Abstract

Introduction: Anesthetic injection is the dental procedure that produces the greatest negative response in children. Pain and anxiety can reduce the efficacy of anesthesia in pediatric patients. In the arena of pediatric dentistry, successful delivery of local anesthesia is an essential component of positive treatment outcomes. For many individuals, the experience of pain with dental procedures can lead to their future avoidance of much needed oral health care due to dental fears and anxiety. A child's early positive experiences can lead to a lifetime of healthy perceptions and attitudes towards dental health. The aim of this study was to assess the knowledge and use of topical and local anesthetic agents in pediatric oral procedures amongst the dentists.

Materials and Method: A closed- ended questionnaire comprising 12 questions based on type, procedural use, effectiveness, and adverse reactions noted to various topical and local anesthetics in pediatric patients was given to 150 dental practitioners. Data was analyzed by computing the percentage response for each question.

Results: The results show that 50% of the dental practitioners treating pediatric patients always used topical anesthesia prior to local anesthesia. 76%used topical in spray form. 69% of the practitioners used 4.4mg/kg dosage of LA. 55% of the respondents preferred the use of a 25 gauge needle.

Conclusion: Thisstudy concludes that dental practitioners treating pediatric patients consider topical anesthesia to be effective when used prior to LA and preferred short length needle with 25 gauge.

Key Words:*Local anesthesia, topical, Treatment, pediatric, Needle*

Introduction

Behavior management in pediatric dentistry comprehends various essentials ranging from creating a pain-free environment to reception of treatment by a child [1].The goal of providing “painless” dental care has been actively sought after for decades. In pediatric dentistry, successful delivery of local anesthesia is an essential component of positive treatment outcomes. According to the American Academy of Pediatric Dentistry, the prevention of pain during dental procedures can nurture the relationship of the patient and dentist, build trust, allaying fear and anxiety, and promoting a positive dental attitude [2]. In order to instilla positive attitude towards dental care among the patients, proper injection technique, topical anesthetics, dosage and time should be followed[3,4,5]. Many advances have been made in topical anesthetics, types of anesthesia, volume, location, and pre-operative patient management that have been used to improve overall patient care[6,7].

Local anesthesia causes temporary loss of sensation in one part of the body without depressing the level of consciousness with the use of a topically-applied or injected agent [8]. Local anesthetics act within the neural fibers to inhibit the ionic influx of sodium for neuron impulse[9,10]. This helps to prevent transmission of pain sensation. The two general types of local anesthetic formulations are: Esters (eg, procaine, benzocaine, tetracaine) and Amides (eg, lidocaine, mepivacaine, prilocaine,articaine)[11]. The local anesthetic blocks the action of a specialized gate called the sodium channel. The nerve signals cannot be transmitted when the sodium channel of a nerve is blocked. The only location at which the local anesthetic molecules have access to the nerve membrane is at the nodes of Ranvier, where there is an abundance of sodium channels. The interruption of a nerve signal in a myelinated nerve occurs when nerve depolarization (the nerve signal) is blocked at three consecutive nodes of ranvier.Local

anesthetics create a chemical road block between the source of pain and the brain by interfering with the ability of a nerve to transmit electricalsignals or action potentials [10].

Epinephrine, levonordefrin, norepinephrine are vasoconstrictors which can be added to local anesthetics to constrict blood vessels in the area of injection. Theyhelp to prolong the anaesthetic action by decreasing the rate of absorption of the local anesthetic into the blood streamandthereby lowers the risk of toxicity [12].A local anesthetic without a vasoconstrictor also can be used for shorter treatment needs but should be used with caution to minimize the risk of toxicity of the anesthetic agents.

Because of lower weight when compared to adults, young children are more likely to experienceanesthetic overdose or toxicity. Most adverse drug reactions occur within 5-10 minutes of injection. Overdose of local anesthetics are caused by high blood levels of anesthetic as a result of an inadvertent intravascular injection or repeated injections. Local anesthetic overdose outcomes depression of the central nervous system. Early subjective symptoms of the central nervous system include dizziness, anxiety and confusion and may be followed by diplopia, tinnitus, drowsiness and circumoral numbness or tingling. Objective signs include muscle twitching, tremors, talkativeness, slowed speech and quivering. Although allergic reactions to injectable amide local anesthetics are rare, patients may exhibit a reaction to thebisulfite preservative added to anesthetics containing epinephrine. Patients with a sulfa allergy should not receivearticaine. Patients may also exhibit allergic reactions to benzocaine topical anesthetics [13,14].

Injection prick is perceived as painful procedure and most children are fearful about the needle prick rather than the dental procedure itself.Topical local anaesthetics (TLA) are frequently used in dental practice to reduce acute and chronic pain and facilitate atraumatic dental treatment. TLA induces temporary loss of sensation up to a depth of 2-3mmon the applied surface [15,16]. Topical anesthetics produce temporary loss of sensationbyreversibly blocking the nerve conduction near their site of administration in a limited area. Nerve impulse conduction is blocked by decreasing nerve cell membrane permeability to sodium ions, possibly by competing with calcium-binding sites that control sodium permeability. Decreased depolarization and an increased excitability threshold occurs due to change in permeability that ultimately prevents the nerve action potential from forming. [17,18,19]TLA is an important prerequisite for many

pediatric dental procedures such as needle penetration, scaling and root planing, mucosal punch biopsies, application of orthodontic appliances and rubber dam clamps, postsurgical pain etc. [20]. The application of a topical anesthetic minimizesthe distress caused during administration of local anesthesia. Topical anaesthesia is effective when they are in contact with the applied site for a minimum duration of 2 minutes,1and lower duration of application might not produce desired clinical effect. Topical anesthetic agents are obtainable in gel, liquid, ointment, patch and aerosol forms.It's disadvantages are the taste may be disagreeable to patient and the length of application time may increase apprehension of approaching procedure in the pediatric patient.Benzocaine or lidocaineare the common topical anesthetics used in dentistry.

Local anesthesia forms the backbone of pain control techniques in dentistry and has a major role in dentistry for children. There is a constant search for ways to find a more comfortable and pleasant means of achieving local anesthesia before dental procedures to avoid the invasive and often painful nature of the injection. Fear of syringes and needles has been reported as one of the major causes of apprehension and anxiety in pediatric patients. Hence, pediatric dentists are on a constant search of tools for painless administration of topical and local anesthesia [21]. Thus, the aim of the present study was to evaluate the knowledge and awareness amongst the general dental practitioners about the appropriate use of topical and local anesthetic agents in pediatric patients.

Materials and Method

A questionnaire was designed for the dentists regarding the type, procedural use, effectiveness, and adverse reactions noted to various topical and local anesthetics in pediatric patients. The survey sampled one hundred and fifty general dental practitioners in Chennai city,India. The survey consisted of 12-items in multiple choice/answer format. The survey consisted of several questions related to the usage of local and topical anesthetics, the adverse reaction to the anesthetics, the needle size and gauge used,dosage and waiting time after the application of topical anesthetic before injecting. The survey also asked the clinicians to provide demographic data such as the name, age, sex and year of study. Data was analyzed by computing the percentage response for each question.

Results

Question	Response	MaxResponse	Response	MinResponse
Use of topical anesthesia	Always	50%	Never	3%
Type of topical anesthesia	Spray	76%	Ointment	3%
Time waited after application of topical anesthesia	31-60sec	40%	<10sec	12%
Effectiveness of topical anesthesia	Effective	60%	Poor	3%
dislike to topical anesthesia	Taste	76%	Colour	1%
Adverse reaction to TLA	0	71%	4-6%	3%
Times TLA works	75%	45%	100	3%
Dosage of LA	4.4mg/kg	69%	10mg/kg	2%
Factor considered during dosage	Body weight	74%	Others	5%
Gauge of needle	25 gauge	55%	30 gauge	9%

Length of needle	Short	71%	Long	29%
Time taken to inject	31-60sec	41%	<10sec	7%

Table 1 Responses of the practitioners to the questionnaire

The results show that 50% of the dental practitioners treating pediatric patients always used topical anesthesia prior to local anesthesia and 3% never used. For the question regarding the type of topical anesthesia used, a majority of the respondents (76%) used spray form and only about 3% used it in the form of ointment. When the respondents were asked about the waiting time before injecting, 12% waited only for <10sec and 40% waited for31-60 seconds. When asked about the effectiveness of topical anesthetics, 60% perceived them effective and 3% perceived them poor.When questioned concerning the different properties of topical anesthetic, according to the dental practitioners most of their patients did not like the taste (76%). The adverse drug reactions to topical anesthetics in pediatrics seen in the last year of practice were also examined. Most of the practitioners (71%) reported that their patients did not experience any adverse reactions to the topical anesthetic, while only 3% of the practitioners reported that 4-6% of their patients experienced an adverse drug reaction. When practitioners were asked the percentage of times they felt that the topical anesthetic worked, 45% felt that the topical worked 100% of the times and 3% felt that it never worked. 69% of the practitioners used 4.4mg/kg dosage of LA while 2% said it is 10mg/kg (figure 1).

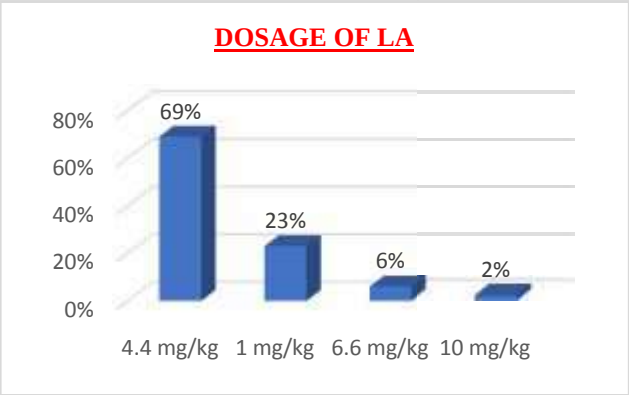

Figure 1: Dosage of LA(%).

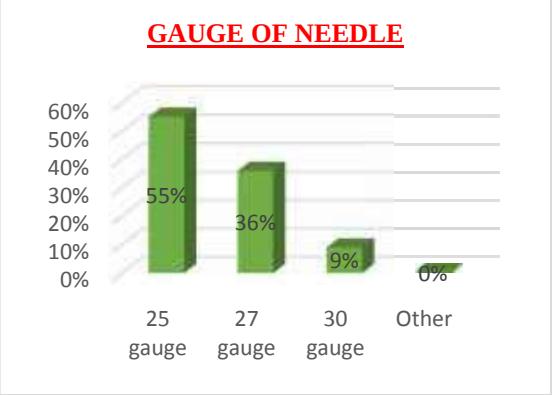

Figure 2: Gauge of needle used(%)

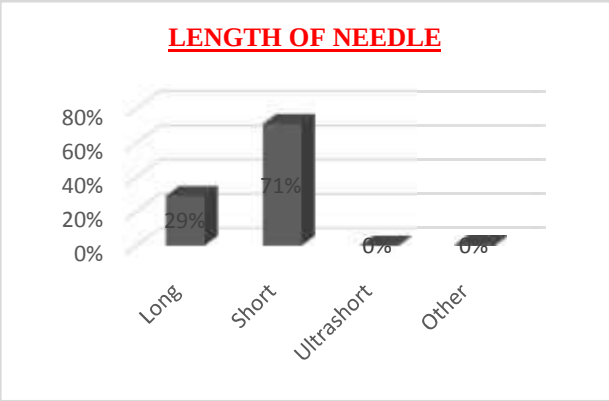
When questioned which criteria practitioners used to determine the local anesthetic dosage, 74% of the respondents reported using the exact body weight when determining the dosage of local anesthetic for each pediatric patient. The commonly used gauge sizes by the practitioners showed that 55% of the respondents preferred the use of a 25 gauge and 9% used a 30 gauge (figure 2). The length of needle used for pediatric patients was short length needles (figure 3).



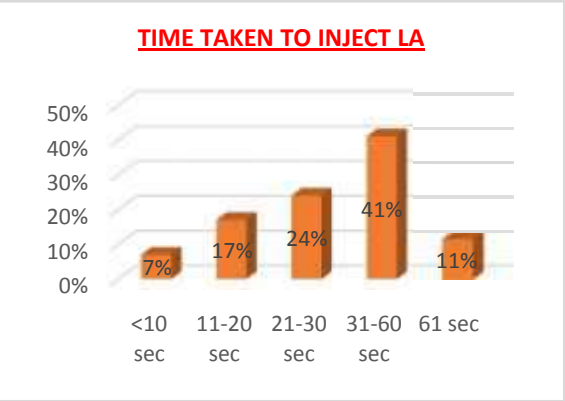


Figure 3: Length of needle used(%)

Figure 4: Time taken to give LA(%)

When questioned regarding the amount of time taken to inject a full cartridge of local anesthetic, 7% took less than 10 secs and 41% took 31-60 secs (figure 4).

Discussion

The questionnaire was distributed among dental practitioners which included 83% females and 17% males between age groups of 20-27 years. Majority of the dentists always use topical anesthesia when treating pediatric patients. Topical anesthesia when used appropriately can improvepatients behaviors and attitudes and provide a safe and positive treatment outcome [22].The type of topical anesthesia commonly used is the spray form. Many options to deliver anesthesia have developed over the last several decades. Most of the practitioners use the spray form of topical anesthesia for pediatric patients. Electronic dental anaesthesia (EDA), precooling, vibration, iontophoresis, and sonophoresis are some alternative techniques that can be used for producing topical/surface anaesthesia.

As for the waiting time after application of topical anesthetics, the recommend waiting time is 10-30 seconds before injecting depending on the form of the preparation. Earlier studies recommended 60 seconds or longer before injection to assure maximum efficacy of topical anesthetics [23]. Others recommend a waiting time of approximately 30 seconds [24].Stern and Giddon showed that, application of a topical anaesthetic to mucous membrane for 2 to 3 minutesleads to profound soft tissue analgesia [25].

Most practitioners responded that the current topical anesthetics they were using were effective, while about 3% thought they were inadequate.Most practitioners responded that their patients disliked the taste of the topical anesthetics.

In this survey, very few practitioners reported any adverse reactions from the local and topical anesthetics. Majority of the practitioners felt that the topical anesthetics work when applied prior to the local anesthesia. Many local anaesthetics used effectively via injection prove ineffective when applied topically (e.g., articaine, mepivacaine, prilocaine, procaine), because, the concentrations necessary to produce anaesthesia via topical application are high, with significantly increased overdose and local tissue toxicity. Higher concentration also increases the risk of toxicity, locally and systemically if the drug is efficiently absorbed. Allergic reactions are more common with ester type when compared to amide type. The risk of overdose with amide topical anaesthetics is greater than that with the esters and increases with the area of application of the topical anaesthetic. Because topical anaesthetic formulations do not contain vasoconstrictors and local anaesthetics have vasodilatory properties, vascular absorption of some topical formulations is rapid, and blood levels may quickly reach those achieved by direct IV administration. Preservatives, such as methylparaben, and other ingredients may also cause allergic reactions. Toxic reactions to local anaesthetics are more common after topical than via any other route of administration. It is the amount of drug administered that is important with regard to toxicity and topical agents are usually available in concentrations much greater than are found in injected formulations. Local anesthetic toxicity can be prevented by careful injection technique, watchful observation of the patient, and knowledge of the maximum dosage based on weight. Practitioners should aspirate before every injection and inject slowly [26].

With the question of the factor used to determine the dosage of local anesthetic, majority of the practitioners chose using body weight as an important factor while calculating the dosage. Malamed recommended the use of exact body weight to prevent anesthetic overdose.

Needle selection should allow for profound local anesthesia and adequate aspiration. Larger gauge needles provide for less deflection as the needle passes through soft tissues and for more reliable aspiration [27]. The depth of insertion varies not only by injection technique, but also by the age and size of the patient. The survey showed that a high percentage of pediatric dentists are using needles with a diameter (25 gauge) smaller than recommended. Malamed recommends the

use of a 25-gauge needle for all injections in highly vascular areas and 27-gauge needle can be used for all other injection techniques provided the aspiration percentage is exceedingly low [28]. Trapp and Davies have reported positive aspiration through 23-, 25-27- and 30-gauge needles. However, the question as to which the appropriate needle gauge isremains, and it is universally agreed upon that the anesthetic solution must be injected slowly, and the dentist should observe the patient carefully for any unexpected reactions [29].Malamed also recommends the length of the needle to be long for all techniques requiring penetration of significant thickness of soft tissue. Short needles may be used for injections that do not require penetration of significant depths of soft tissue. If using a smaller diameter is justified to prevent visual excitation of the patient, it must be noted that the diameter difference is almost negligible to the unaided eye. Needles should not be bent if they are to be inserted into soft tissue to a depth of greater than five millimeters or inserted to their hub for injections to avoid needle breakage[30].

As for the time taken to inject a full cartridge of anesthetic, a slow injection is important for two reasons: 1) for the safety of the patient and 2) to avoid the solution from tearing the soft tissues into which it is being injected. Rapid injection causes an immediate discomfort that last a few seconds followed by a prolonged soreness long after the numbing effect of the local anesthetic has subsided [31].Malamed recommends at least 60 seconds for a full 1.8ml of cartridge as this rate of deposition will not produce tissue damage either during or after anesthesia, nor will it cause a serious reaction in an event of accidental intravascular injection.48%of the surveyed pediatric dentists were injecting a full cartridge with a time of less than sixty seconds.

Conclusion

The findings of this study demonstrate that dental practitioners treating pediatric patients consider that topical anesthesia are effective when used prior to LA and are most commonly using spray form as the preferred type of topical anesthesia. Topical and local anaesthetics are most important armamentarium for pediatric dentists to make dental procedures atraumatic for the children.

Abstract

Introduction: The design of prosthetic replacement depends upon the patterns of partial edentulism. The aim of classification of partially edentulous arches is to facilitate the communication of prosthesis designs and treatment options among professional colleagues, students and technicians. The aim of this study was to determine the prevalence of various classes of Kennedy's classification in patients reporting to Saveetha dental college.

Materials and Methods: 170 patients were recruited in this study from February 2015 to May 2015 of age group 30 to 60. Kennedy's classification was utilized after applying Applegate's rules to record the partial edentulism.

Results: 101 male patients and 69 female patients participated in this study. Out of this, 71 were bite cases and 99 were single arch cases. Partial edentulism in the maxillary arch was found in 22.3% patients, while 35.9% patients had partial edentulism in mandibular arch. The remaining 41.8% of patients had missing teeth in both arches. Kennedy's class I was found to be most common, while Kennedy's class IV the least common.

Conclusion: A higher frequency of tooth loss due to dental caries and negligence of oral health among the patients in this study is quite alarming and is suggestive of need to create awareness among dental health care system for timely prevention of diseases and factors leading to tooth loss. By bringing about awareness of tooth loss and available treatment options, the dental needs of the community could be met leading to an overall improvement in their quality of life.

***Key Words**: Applegate's rules, Kennedy's classification, Maxilla, Mandible, Partial edentulism*

Introduction

Teeth are the key entities of stomatognathic system for mastication, phonation and aesthetics [1, 2]. Many options are available for replacing missing teeth like removable partial dentures, fixed partial dentures and implant-supported prosthesis[3]. Conservative treatment modalities used to treat partial edentulism in patients, such as dental implants also happen to be the most expensive. This happens to limit their availability to lower socioeconomic groups[4]. Hence, it should not be much of a surprise that conventional removable prosthodontic treatment modalities continue to outnumber implant tooth replacements in general dental practice. Removable partial prosthesis is a versatile, cost effective and reversible treatment method for partially edentulous patients of any age. The design of prosthetic replacement depends upon the patterns of partial edentulism. The aim of classification of partially edentulous arches is to facilitate the communication of prosthesis designs and treatment options among professional colleagues, students and technicians. The classification is also helpful in recording history of patients[5]. Different Prosthodontists had proposed many classification systems[6]. Each classification system is associated with its own merits and demerits. The ultimate goal of any classification system and is, improved communication and consistency within the dental professionals. Different classifications may also have associated treatment principles that assist in treatment standardization and teaching. Kennedy's system of classification is most widely used[7]. The Kennedy classification system's main differentiating factor is its ability to quickly and clearly demonstrate the location of tooth support in relation to edentulous spaces. Due to its simplicity, it does not make judgments regarding condition or position of the remaining teeth. There are many instances, in which Kennedy's classification is difficult to apply. For such special situations Applegate's rules are applied[8]. The objective of this study was to determine the prevalence of various patterns of partial edentulism, using Kennedy's classification system, of patients reporting to Saveetha Dental College and Hospitals.

Materials and Methods

This study was undertaken in Saveetha Dental College Hospitals from February 2015 to May 2015. After approval from institutional ethical review Committee, the data for this study was compiled from the patients fulfilling the inclusion criteria. Name, age, gender, cause of tooth loss, periodontal health and Kennedy's class along with modification spaces were recorded. Informed consent was taken from all patients. History was taken, which was followed by detailed clinical examination for partial edentulism. Whether only anterior or only posterior or both anterior and posterior teeth were missing was recorded. If assessment of missing anterior teeth was in question, anterior teeth were considered missing, if the patient's prosthesis consisted of a prosthetic anterior tooth. This avoided misrepresentation of large diastema's or spaces closed due to tooth migration. The total number of missing teeth was recorded. Fixed prosthodontic pontics and closed spaces were not considered missing teeth. Kennedy's classification system modified by Applegate was used in this study.

Results

A total of 170 patients with partial edentulism were examined, in which 101 were male patients and 69 were female patients. Out of this, 71 were bite case and 99 were single arch cases, resulting in examination of 241 dental arches in total. Partial edentulism in maxillary arch was found in 22.3% patients, while 35.9% patients had partial edentulism in mandibular arch. The remaining 41.8% of patients had missing teeth in both arches (Table 1). Caries are found to be the most common cause of tooth loss in patients with edentulism (72.4%) followed by periodontal diseases (17%). The distribution is given in Fig.1. Kennedy's class I (44.3%) was found to be most common, while Kennedy's class IV (11%) the least common (Fig 2). Male predilection is higher in all Kennedy's classification than female (Fig 4).

Table 1: Distribution of Kennedy's classification according to dental arches

DENTAL ARCH	MALE	FEMALE	TOTAL n (%)
MAXILLA	20	18	38 (22.3)

Discussion

The presence or absence of teeth acts as a good indicator of the oral health of an individual in general. Oral health is an important component of both overall health and quality of life, as oral health and general health are interdependent. Oral disease creates a major public health burden worldwide and receives inadequate attention in many low- and middle-income countries [World Health Organization (WHO)] [9]. Systemic conditions have oral manifestations that increase the risk of oral disease, which in turn is a risk factor for various systemic diseases. Tooth loss is recognized as an individual risk factor for a range of systemic conditions, such as hypertension, stroke, cardiovascular disease, diabetes and coronary heart disease. Tooth loss affects the quality of life of an individual resulting in reduced efficiency and function of the masticatory system and the appearance of the individual. By reduced chewing ability in individuals with tooth loss, nutritional deficiencies may be seen, and intakes of certain foods could probably be reduced. There is strong evidence that a diet high in fruits and vegetables improves systemic immunity and protects our body against obesity, diabetes, cardiovascular disease, and many other

cancers[10]. The recommended intake of fruits and vegetables is 400 gm/day. Thus, tooth loss will ultimately lead to the poor dietary intakes which in turn causes poor nutritional status. Masticatory performance and biting force are greater in dentate individuals followed by partially edentate and completely edentulous individuals[11]. Most of the patients evaluated in this study had missing posterior teeth, and in such partially edentulous subjects, biting force and masticatory ability is very much lower compared to dentate individuals, which was the prime concern in replacing the missing posterior teeth. Enlargement of the tongue, reduction in the vertical dimension, interocclusal space and lower facial height of the individual are few common effects of tooth loss. The reasons for tooth loss may be due to dental caries, periodontal disease, traumatic accidents, impaction, orthodontics, supernumerary, preparation for radiotherapy, or even due to congenital and developmental disorders[12]. The two most common causes of tooth loss in Asian population are dental caries and periodontal disease[13]. Secondary reasons for tooth loss are restricted access to dental services, health systems, and lack of oral health care[14]. These individuals with a high percentage of tooth loss need prosthetic restorations to restore the form, function, and aesthetics.

Several methods have been proposed to classify the partially edentulous arches on the basis of the potential combinations of teeth to ridges. At present, Kennedy's classification is probably the most widely accepted one. Kennedy divided all partially edentulous arches into four main types. In his classification, edentulous areas, other than those determining the main types, were designated as modification spaces. The Kennedy classification is as follows[15]

Class I. Bilateral edentulous areas located posterior to the remaining natural teeth.

Class II. A unilateral edentulous area located posterior to the remaining natural teeth.

Class III. A unilateral edentulous area with natural teeth remaining both anterior and posterior to it.

Class IV. A single but bilateral (crossing the midline) edentulous area located anterior to the remaining natural teeth.

The results of this study showed that the frequency of partial edentulism is higher in mandible than maxilla in our population and Class 1 is the most common and Class 4 is the least common. This is in concordance with the study carried out by Curtis et al[16], at University of California, school of dentistry. Anderson et al[17] investigated the prevalence of the classification of removable partial dentures at Birmingham Dental Hospital in the United Kingdom. Out of a total

of 417 removable partial dentures, 208 (49.9%) were Kennedy Class I, 76 (18.2%) Class II, 101 (24.2%) Class III and 32 (7.6%) Class IV. This was the earliest study of Kennedy classification prevalence. Basker et al and Davenport et al[18] conducted survey in three commercial dental laboratories in the United Kingdom, resulting in examination of 80 maxillary and 44 mandibular cast metal framework removable partial dentures. Kennedy Class III (69%) was the most frequent maxillary removable partial denture while Class II was the most frequent in the mandibular arch (43%). Interestingly, the study was repeated 10 years later for comparison purposes[19]. This time five commercial dental laboratories were surveyed for a total of 330 frameworks examined. Kennedy Class III (55%) was still the most common maxillary removable partial denture, though the frequency decreased. Kennedy Class I was the most common mandibular removable partial denture found. These differences may have been due to chance or possible changes in tooth loss and treatment selection. Bergman et al[20] did a long-term follow-up consisting of 33 removable partial denture patients in Sweden. Two cases were Class II and a single case was Class III. Of the 30 Class I removable partial dentures, 25 were mandibular. Wetherill et al and Smales et al[21] conducted a survey in which, a total of 150 RPDs was thereby assessed. A distinct difference between maxillary and mandibular arches was seen. 60 out of 86 mandibular removable partial dentures were Class I. 29 Class II and 21 Class III maxillary removable partial dentures were found from the total of 64. Schwalm et al[22] conducted a survey in which 161 patients were examining in which the Class I RPD was the most common followed by Class III, II and IV respectively. Filiz keyf et al[23] analyzed the distribution of partial edentulous patients who sought treatment for removable partial denture in clinics using Kennedy classification. This study showed Class I had a large distribution in the mandible, while class II in maxilla. In contrast to our study, Lana A. Shinawi et al[24] investigated the frequency of different pattern of partial edentulism in 200 patients in King Abdul Aziz University, showed that Kenney's class III was most predominant. A R Jain et al[25] studied the prevalence of partial edentulism in South Indian rural population. The results of this study showed that Kennedy's class III was most prevalent in both maxilla and mandible. Al Dawairi et al[26] in a study investigated the frequency of different pattern of partial edentulism of 200 patients in Jordan. In this study Kennedy's class III pattern of partial edentulism was most commonly encountered in both maxilla (47%) and mandible (45%). Sadig and Idowu et al[27] carried out a study in Saudi population on 422 partially dentate patients in which they concluded that Kennedy's class III in

both maxilla and mandible were common. Maqsood et al[28] in study of partial edentulism based on Kennedy's classification carried out on 395 patients in Isra Dental College outpatient department in Hyderabad, showed that Kennedy's class IV was most prevalent in both arches. A study carried by Hassan et al[29] at Armed Forces Institute of Dentistry, Pakistan on 1000 partially edentulous patients showed that Kennedy's class III was most common in maxilla (60.9%) and mandible (46.8%).

Conclusion

The result of the distribution of various classes of Kennedy's classification is almost similar to most of the other studies. The higher frequency of posterior tooth loss is suggestive of a greater need to create awareness in patients about oral hygiene maintenance and early restorative management of carious lesions. The higher frequency of class 4 in male patients requires emphasis on safety measures for trauma prevention and advances in aesthetic dentistry.

Abstract

Introduction: The consumption of soft drinks has increased dramatically over past several decades. Dentists are becoming more concerned about over consumption of soft drinks which results in dental disease. All soft drinks are acidic which corrodes the teeth by eroding its enamel. The high measure of sugar expended through soda pops prompt the advancement of microscopic organisms that assault the teeth along these lines exasperating dental issues.

Material and Method: A questionnaire with 7 questions was made on oral health hazards on taking aerated soft drinks among adolescents was conducted between Dec to March 2016.

Results: This study showed 65% females of age group 10-19 years and 60% males of age group 10-19years had the habit of consuming carbonated soft drinks.

Conclusion: The findings of the present study indicate a high rate of soft drink consumption among adolescents. In order to diminish the use of carbonated drinks by population it is necessary to provide appropriate training for the adolescents about the adverse effects of soft drinks and the oral health knowledge.

Key Words: *soft drinks, adolescents, survey, carbonated*

Introduction

A soft drink is a beverage that is carbonated and it has become a highly visible with increase energy intake and body weight (1).Generally soft drinks are composed of filtered water, artificial additives and refined sugar. They usually lack nutritional value and add up calories

and it makes you gain weight. It has been found that dental erosion is considered as a clinical problem in the oral health of school children and young adults and acidic drinks are thought to be an important cause(2).High consumption of soft drinks and other sugary drinks are associated with a number of health problems, including overweight and obesity, type 2 diabetes, osteoporosis and dental caries(3).High soda pop consumption is linked with widespread demineralisation of enamel and extensive caries in pits and fissures and in the inter proximal areas(4).The soda pops are thought to make harm the teeth in view of two properties – to start with, the low pH and corrosiveness of a few beverages can cause disintegration on the polish surfaces and besides the fermentable starch in drinks is processed by plaque miniaturized scale living beings to produce natural acids in the dental plaque and spit, bringing about demineralisation and prompting dental caries(5). People are devouring sodas relatively consistently without knowing the evil impacts and the mischief of sodas on their dental and general wellbeing. Thus this study aimed to assess the level of knowledge and attitude towards oral health hazards on taking carbonated soft drinks among adolescents(6). Causative components for tooth disintegration are isolated into extraneous and inborn classes. Inborn disintegration happens from automatic gastrointestinal unsettling influences, for example, gastroesophageal reflux ailment (GERD) and from intentional disgorging of gastric acids showed by anorexic as well as bulimic people(7). Outward tooth disintegration causes incorporate natural elements, medicaments, way of life, and eating regimen. In present day social orders the outward factor is ending up more critical, because of the expanded utilization of corrosive beverages as soda pops, don drinks, organic product squeezes and natural product teas(8).Dental examination found that crescent-shaped lesions were present on the cervical region of the buccal and labial surfaces of the teeth of the patients(9). The individual manner of drinking acidic soft drinks has been said to affect how long the teeth are in contact with the erosive challenge and therefore influence the pattern of destruction caused by them. The drinking method strongly affects tooth-surface pH and thereby the risk for dental erosion. Six different methods of drinking were tested in a randomized order by Johansson et al. : holding; short-sipping; long-sipping; gulping; nipping; and sucking(10).Patient should avoid toothbrushing enamel which has been softened by exposure to black cola this may cause additional material loss due to tooth brush abrasion Kids ought to be urged to drink acidic beverages rapidly and utilize a straw with the goal that the fluid is pushed to the back of the mouth.Also, avoid buying re-sealable bottles and discourage sipping over a long period of time. The liquid fruits can be used as a natural

alternative to synthetic beverages(11). Hence this study aimed to bring awareness about carbonated drinks among adolescents.

Materials and Methods

This is an institutional based study conducted to determine the level of knowledge and attitude towards oral health hazards on taking carbonated soft drinks among adolescents.A self-administered questionnaire survey was conducted among patients between the age group of 10-19years. This survey was conducted between Dec to March 2016. A convenience sample of 150 adolescents were the target population .In this study, a questionnaire was prepared, which consists of 7 questions related to knowledge of oral health hazards on taking carbonated soft drinks among adolescents .The aims and objectives were explained to all the adolescents before starting the study. Questions were manually checked for completion of data. All data were entered in MS Excel spreadsheet, and the percentage was calculated.

Results

The study was conducted between males and females of age group 10-19years. Of these 87 were males and 63 were females. This study showed 65% females of age group 10-19 years and 60% males of age group 10-19years had the habit of consuming carbonated soft drinks. It was found that 30% of females consumed carbonated drinks in daily basis and 20% of males consumed carbonated drinks in daily basis. Regarding the question awareness of consumption of soft drinks it was found that 28% females of age group 10-19years, 30% males of age group 10-19years were aware of consumption of soft drinks would erode tooth enamel. When asked about any sensitivity on taking aerated soft drinks

it was found that 60% females and 65% males experienced sensitivity in taking aerated soft drinks. Thus the awareness programme regarding the oral health hazards of carbonated soft drinks are less, overall only 65% of adolescents are aware of it.

Table 1: Questionnaire

FEMALE:

AGE GROUP: 10 – 19 years

Questions	Sample	%
1. Consumption of soft drinks among patients in varying dental office	41(yes) 22(no)	65% 34%
2.Frequency of consumption of soft drinks	25(daily basis) 21(weekly basis) 17(monthly basis)	39% 33% 26%
3. Necessity of drinking a soft drink	23(taste) 40(refreshment)	36% 64%
4. Ill effects of consuming soft drinks	20(yes) 43(no)	30% 68%
5. Awareness of acids present in soft drinks	29(yes) 34(no)	46% 53%
6.awareness of consumption of soft drinks would erode tooth enamel	22(yes) 41(no)	30% 65%
7.experienced any sensitivity on taking aerated soft drinks	38(yes) 25(no)	60% 39%

MALE:

AGE GROUP: 10 – 19 years

Questions	Sample	%
1. Consumption of soft drinks among patients in varying dental office	53(yes) 34(no)	60% 39%
2.Frequency of consumption of soft drinks	28(daily basis), 18(weekly basis), 5(monthly basis)	32% 20% 5%
3. Necessity of drinking a	34(taste)	39%

soft drink	53(refreshment)	60%
4. Ill effects of consuming soft drinks	40(yes) 47(no)	45% 54%
5. Awareness of acids present in soft drinks	41(yes) 46(no)	47% 52%
6.awareness of consumption of soft drinks would erode tooth enamel	26(yes) 61(no)	30% 70%
7.experienced any sensitivity on taking aerated soft drinks	57(yes) 30(no)	65% 34%

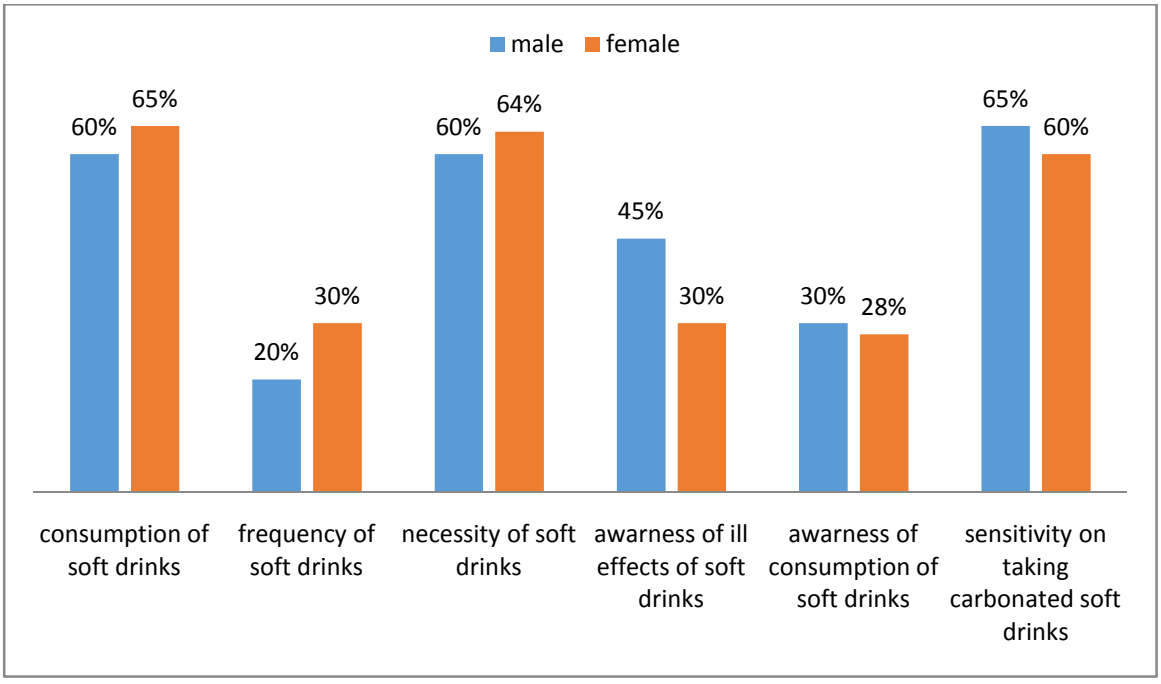

Figure 1: Carbonated drink consumption among adolescents

a)65% of female and 60% of male consumed soft drinks **b)**30% of female and 20% of had the habit of drinking soft drinks frequently **c)**64% of female and 60% of male were aware of the necessity of soft drinks **d)**45% of male and 30% of female were aware of the ill effects of soft drinks **e)**30%of malesand 28% of females were about of consumption of

soft drinks **f)**65% of males and 60% of females had sensitivity on taking carbonated soft drinks.

Discussion:

Soft drinks are now considered to be the most important etiological factors for enamel erosion(12). It is well known that disease loves acid, and particularly true of dental caries' common problem that is associated with consumption of a large number of soft drinks is the increased acid levels throughout the body. Dental cavities are often associated with carbonated beverag(13). This association is important because the amount of sugars that are consumed is important in forming caries, which is when a cavity affects only the enamel, the outer protective layer of a tooth(14). Soft drinks have been extensively investigated over a long period of time and are one of the principle factors in the etiology of extrinsic dental erosion(15).

Study was conducted to assess the knowledge of oral health hazards on taking carbonated soft drinks among patients in varying dental office. Our study was conducted between female and male of age group 10-19years. Among the female of age group 10-19years was found that 65% preferred carbonated soft drinks. Among the male of age group 10-19years was found that 60% preferred carbonated soft drinks. Another study by Gupta,et.al 2015 was found that 73% of students preferred carbonated drinks. An examination by priyadharshini et al indicated 78.5% of the young people among chennai populace are dependent on carbonated refreshments. Among the age group of 10-19years female was found that 30% consumed soft drinks in daily basis and among male of age group 10-19years was found that 20% consumed soft drinks in daily basis. Another study by Dehdari, et al Nov 2011 showed the result of frequency of using drinks is daily for 8.1% of students, 5-6 times per week for 10.8%, 3-4 times per week for 22.1%.

When asked about the ill effects of consuming soft drinks among females it was found that 30% were aware. When asked among male it was found that 45% were aware of it among age group of 10-19years.Another study by Heller kEet.al Nov 2001 showed a result of 78.47 % students had read about ill effects of carbonated drinks. In our present study it was found that 28% of females and 30% of males were aware that consumption of soft drinks would erode

tooth enamel and cause caries. Heller et al, using 1988–1994 U.S. data, determined that there were significant increases in caries rates in adults aged 25–34 with increased consumption of soft drinks.

About 60% of females and about 65% of males of age group 10-19years experienced sensitivity on taking aerated soft drinks. Study by Gupta,et.al 2015 showed only 48% of the students felt discomfort within few minutes of consuming soft drinks. A study byMahumuthaAffshanasuggest that erosion is as prevalent in chennai a,one adolescents. Possible reason may include Sampling variation or regional variations. Hence our present study found that females are consuming soft drinks at higher rate when compared to males also found that adolescents are at higher risk of consuming carbonated soft drinks

Conclusion:

The findings of the present study indicate a high rate of soft drink consumption among adolescents. In order to diminish the use of carbonated drinks by population it is necessary to provide appropriate training for the adolescents about the adverse effects of soft drinks and the oral health knowledge. Most of them preferred to drink aerated soft drinks in spite of being aware of the ill-effects of carbonated drinks. Hence the oral knowledge, attitude and practice among the population is still below the satisfactory level.

A Survey on Awareness of Protein Energy Malnutrition in Below Poverty Line People

Thejeswar EP [1], Brundha M P [2], Thummala Bhagya Lakshmi [3]

Graduate Student [1],Senior lecturer[2],Department of General Pathology

Senior Lecturer [3],Department of Pedodontics and Preventive Dentistry

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: India has provided with a number of nutrition analysing programs, but malnutrition remains highly widespread in the poor states of the country. Malnutrition results due to the imbalance in needs of the body to the intake of nutrients. It may be due to poverty, lack of awareness and illiteracy.The aim of the study is to analyse the awareness of protein malnutrition among below poverty line people, by questionnaire method.

Material and method: The present study was undertaken for below poverty line people from rural areas in Chennai district, Tamil Nadu, India. A questionnaire consisting of 10 questions were framed based on knowledge about protein-energy malnutrition and they were given to 300 below poverty line people of Chennai.

Result: This study showed that (74%) people aware of protein-energy malnutrition, and family members were the most common source of information on protein-energy malnutrition.

Conclusion: Protein malnutrition might have a serious impact on health especially in growing children as well as in adults. Creating awareness about the importance of proteins among people who are under below poverty line becomes a significant factor of study.

Key Words: *Protein energy malnutrition, Marasmus, Kwashiorkor, Poverty, children.*

Introduction

India has provided with a number of nutrition analysing programs, but malnutrition remains highly widespread in the poor states of the country. Malnutrition results due to the imbalance in needs of the body to the intake of nutrients. It may be due to poverty, lack of awareness and illiteracy[1]. In the present study, Protein Energy Malnutrition (PEM) in the below poverty line people from rural areas was measured. Moderate and severe malnutrition was observed in the various categories of age.In additional occupation and annual income were analysed in the study and it was found that these conditions may be the main reason for the Protein-energy malnutrition. A wide variety of development actions are needed to improve the food security and nutrition among the population[2]. Nutritional problems in India have their roots in poverty and inequality[3]. Poverty which restrains an individual or family to establish command over "Commodity Bundles with Enough Food" and inequality among other things places a disproportionate burden of ill health and under-nutrition on women and children[4]. Malnutrition and its associated disease conditions can be caused by eating too little, eating too much, or eating an unbalanced diet that lacks necessary nutrient[5]. Under-nutrition is defined as failure to consume adequate energy, protein, and micronutrients to meet the basic requirements for body maintenance, growth, and development[6]. Malnutrition is one of the most devastating problems worldwide and is intensively linked with poverty[7-8]. This paper mainly focuses on the malnutrition and health status of below poverty line population. The oppression of people socially and culturally means they have less access to everything, including food, resources, healthcare, community support, and information. Hence, significant steps should be taken to educate and to make them aware against the terrible problems of malnutrition and thereby providing proper awareness for below poverty line people in the rural areas is the significant factor of this research.

Materials and Methods

The present study was undertaken for below poverty line people from rural areas in Chennai district, Tamil Nadu, India. A questionnaire consisting of 10 questions were framed based on knowledge about protein-energy malnutrition and they were given to 300 below poverty line people of Chennai. This was a cross-sectional Study; hence it has a self-developed questionnaire, consisting of both open and close-ended questions related to various aspects of knowledge about protein-energy malnutrition. Study population between age group 20-50 years were selected. The aim and purpose of the study were clearly explained and discussed with them population prior to the survey. The respondents were interviewed with the questions and corresponding answers were marked.

The questionnaire was in two parts. The first part had questions on demographic information of the respondents such as Name, age, gender, etc. The second part contained questions such as basic knowledge

on protein-energy malnutrition, the source of knowledge, causes, and risk factors as well as about treatment of it. The questionnaire was framed in such a way for easy understanding and filling by respondents.

Results

This questionnaire is based on the awareness of protein-energy malnutrition, which includes causes, signs, symptoms, investigation, prevention and treatment. Out of 300 responders, 174 people were male, while remaining 126 people were female. This study showed that (74%) people aware of protein-energy malnutrition, and family members were the most common source of information on protein-energy malnutrition. People think that dietary deficiency is the major cause of protein-energy malnutrition and knowledge about the risk factors were mostly identified as low socio-economic conditions. People were not aware of different types and laboratory investigations for protein-energy malnutrition. Provision of immunization was found to be an important factor in managing a child. This study also showed that most people were aware of symptoms associated with protein-energy malnutrition but not aware of its risk factors.

Discussion

When enquired about the source of knowledge, the Family was the most common source of knowledge for protein-energy malnutrition (34%), followed by Friends (26%), Media (16%), Relatives (10%), office (6%), Doctors (6%), while rest (2%) were not aware of it. The dietary deficiency was the most common cause of protein-energy malnutrition (44%), followed by social inequality (34%), Drought (8%), while (14%) population selected all the above. When questioned about the risk factors of protein-energy malnutrition, (44%) were aware of the risk factors, followed by ignorance of parents about the importance of child's nutrition (30%), child abuse (10%), and infections like diarrhoea (6%); whereas rest (4%) people said they don't know about it. This study also showed that (60%) people do not know the types of protein-energy malnutrition, while (16%) and (14%) people know about marasmus and Kwashiorkor respectively. Provision of immunization was the most common way of managing child with protein-energy malnutrition, followed by correction of specific nutrient diseases, treating super-imposed infection. According to them the Extreme weakness and fatigue were the main symptom of Marasmus, followed by low body weight, chronic diarrhoea, Dryness of skin and peeling of skin and rest (30%) people doesn't know any symptoms of marasmus. The symptoms of kwashiorkor were known to grow or gain weight, loss of muscle mass, fatigue, Diarrhoea, and oedema. The healthy and nutritional diet (66%) is the most common treatment of choice for marasmus, followed by intravenous fluids (16%), oral rehydration solution (10%), Electrolyte imbalance (4%), whereas (2%) people were not aware of it. Increased vitamin and mineral supplements (36%) and increased carbohydrate and protein intake (32%) are the most common treatment for the Kwashiorkor, followed by Electrolyte imbalance (12%), Hypo-glycaemia (10%), while (10%) people do not know about it. Several reports from Germany, the United Kingdom, the United States, and France as recently as the last

decade reported the prevalence of acute malnutrition in hospitalized paediatric patients to be between 6.1%and 24%[9-11]. Global nutritional assessment in children admitted for elective surgery in a tertiary referral paediatric hospital in Toronto and found that (51%) of children were malnourished (36%) had moderate malnutrition, and (15%) had severe malnutrition. Despite differences in methods of assessing malnutrition, these studies clearly document a significant prevalence of malnutrition even in the developed world, particularly in hospitalized paediatric patients. In 2008, Pawellek and colleagues, using Waterlow's criteria, reported 24.1% of patients in a tertiary paediatric hospital in Germany to be malnourished (<90th percentile weight for height), of which 17.9% were mild, 4.4% moderate, and 1.7% severely malnourished[12]. The prevalence of malnutrition varied depending on their underlying medical conditions and ranged from 40% in patients with neurologic diseases, to 34.5% in those with infectious disease, 33.3% in those with cystic fibrosis, 28.6% in those with cardiovascular disease, 27.3% in oncology patients, and 23.6% in those with gastrointestinal disease[13]. Patients with multiple diagnoses were most likely to be malnourished (43.8%). The prevalence and degree of acute PEM in hospitalized paediatric patients are similar to those observed by Hendricks and colleagues almost a decade ago using the same criteria[14]. One of the difficulties in being able to compare prevalence between studies and Centres is the lack of consensus on a uniform definition of malnutrition and its grades of severity. A recent review highlighted the issues of lack of uniform screening tools, poor nutritional data collection, and early identification of those at risk of developing PEM[15]. Worldwide, only 36 countries account for 90% of all stunted children when countries with stunting prevalence of at least 20% were considered. India alone has 34% of the world's stunted children because of its large population, although there is significant variation between its states[16].

Primary protein-energy malnutrition is caused by lack of access to adequate nutrient intake and usually affects children and elderly persons[17]. The functional and structural abnormalities associated with primary protein-energy malnutrition are often reversible with nutritional therapy. However, prolonged primary protein-energy malnutrition can cause irreversible changes in organ function and growth[18].

Secondary protein-energy malnutrition is caused by illnesses that alter appetite, digestion, absorption, or nutrient metabolism and can be divided into three general, but often overlapping, categories:

(1) Diseases that affect gastrointestinal tract function,

(2) Wasting disorders, and

(3) Critical illness.

Gastrointestinal disease can cause protein-energy malnutrition by pre-mucosal (maldigestion), mucosal (malabsorption), or post-mucosal (lymphatic obstruction) defects. The nutritional status of patients with protein-energy malnutrition caused by gastrointestinal tract dysfunction can often be restored to normal if adequate nutritional support can be provided by dietary manipulations, enteral tube feeding, or parenteral nutrition. Wasting disorders, such as cancer, acquired immunodeficiency syndrome (AIDS), and

rheumatologic diseases, are characterized by involuntary loss of body weight and muscle mass in the setting of a chronic illness. More than 85% of the students consume balanced diet among a dental school[19].

These patients often experience wasting because of

(1) Inadequate nutrient intake related to anorexia and possibly gastrointestinal tract dysfunction and

(2) Metabolic abnormalities caused by alterations in regulatory hormones, cytokines, and systemic inflammation.

The alterations in metabolism are responsible for the greater loss of muscle tissue observed in these patients than in those with pure starvation or semi starvation. It was proved that on consuming dates boiled in milk in an empty stomach helps to increase the haemoglobin level[20]. Restoration of muscle mass is unlikely with nutritional support unless the underlying inflammatory disease is corrected. Weight gain that occurs after nutritional support is started is usually caused by increases in fat mass and body water, without significant increases in muscle tissue. Patients with critical illness exhibit marked metabolic alterations, manifested by increased energy expenditure, altered endogenous glucose production and lipolytic rates, and protein breakdown. About 47% of the people prefer to get self-help from the internet to maintain their their nutritional status[21]. Therefore, protein and energy requirements are increased in critically ill patients. However, providing aggressive nutritional support may ameliorate but does not prevent net lean tissue losses without correction of the underlying illness or injury.

It has been claimed that eating balanced diet is beneficial for living healthy. However, some individuals in our society could not stuck with only this limit because chocolate and candies, for example are the main part of their life, which make them extremely happily. Various factors like social, economic status, age, sex, social class, dietary habits are some of the major etiological factors for malnutrition[22]. As a consequence, diet means for many kind of entertainment and happiness. Eventually, without specific food, they may feel tired and unhealthy[23]. To conclude, the balanced diet has brought plenty of positives effects, so once the individual maintains on this nutritious diet, the potential cause of having any disorder would be rare. Nevertheless, those people, who are against eating balanced diets, might understand the value of this diet in future.

Conclusion

This study showed that overall awareness of protein-energy malnutrition was found to be (**74%**) population in which (**66%)** people were mostly aware of health and nutritional diet as a treatment of choice for marasmus. Consequently, unawareness of protein-energy malnutrition was found to be in (**26%**) population. Even though overall awareness was good for protein-energy malnutrition, proper counselling and education must be given to the risk factors, prevention, Treatment, Symptoms of it. Public health programs, programs from NGOs and medical camps must be conducted to educate the people about protein-energy malnutrition.

Acknowledgement

We would like to express our gratitude to all the respondents for spending their valuable time to answer our questionnaire that helped us to successfully complete our study.

A Survey On Complete Denture Patient's Satisfaction

Harini. N.S[1]., Pon Kirubha Robin[2], Sankari.M[3]
Graduate student [1],Senior Lecturer [2],Department of Prosthodontics
Professor [3],Department of Periodontics,
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Aim: The aim of study is to determine the level of satisfaction of the complete denture patients.

Objective: To assess the satisfactory level of complete denture patients after the treatment, to analyse the drawbacks and to enhance the dental treatment in future.

Background: Complete denture is one of the challenging dental procedure in prosthodontics which when done perfectly, will make the smile and hearts of the patients to utmost beauty. Thus, analysing the satisfactory level of the patients is of most value so that any discomfort for the patient can be corrected immediately which will again improve the status and bonding between the patient as well as the doctor.

Material and methods :50 edentulous patients with their maxillary and mandibular complete dentures in use who were seeking prosthetic treatment for relining of their old dentures or the fabrication of new ones were selected for the study. They were surveyed about their satisfaction with the treatment provided with their complete denture. The patients were also informed that their answers will be confidential. Then, the patients photograph along with their oral cavity have been captured for reference. It has been informed to the patients that their photographs captured is only collected for a personal data. The survey ended by collecting the patients' signature with date for the survey reference.

Conclusion: It is been concluded that patients wearing complete denture are mostly satisfied with the treatment but some are not satisfied. This may be due to the personality traits and the behaviour and attitude of the dentist. Moreover, we can also see that there is some amount of

dissatisfactory rate among the patients due to multiple number of visits, outcome of the denture and due to facial expressions. These can be corrected by the dentists by giving an excellent denture with good retention, stability and support and also with most esthetic prosthesis and with minimal visits which should have shorter appointments too which may enhance the satisfactory level for both the patients and dentists. Thus, it is expected that all the treatments provided to the complete denture patients in the future must be satisfactory.

Key Words:*Complete denture, satisfaction, patient, dentist, treatment*

Introduction

The prevalence of edentulism has been decreased during the last three decades especially in the developing countries[1]. However, the interesting fact is the level of edentulism is still high in the developing countries.[2]This is because more people worldwide are advancing into the old age and thus a growing number of edentulous patients are expected [3].Edentulism has a deep impact on the quality of life, which affects an individual's physiological, biological, social and psychological state [4].It can also cause a state of depression which occurs due to disturbances in speech, esthetics, mastication, and a feeling of inferiority because an important part of the person has been lost [5].Thus the treatment of choice for many cases is still the placement of conventional complete dentures [6].However, a considerable proportion of denture wearers are dissatisfied with their complete dentures[7].Several studies have investigated that factors that may affect the patients' satisfaction with their complete dentures may include denture technical quality, condition of residual ridges and patients' gender, age, previous denture experience, and personality [8-9]. Some studies also suggest that patients must always be handled with care or else they might not be satisfied [10].The loss of all the teeth is a traumatic event in a person's life. Subsequent adaptation to complete dentures is influenced considerably by the ability of the person to come to terms with the edentulous condition. Satisfaction with dentures is thought to be influenced primarily by the person's personality [11].Clinicians need to assess the values of a wide range of factors prior to arriving at a decision that represents optimal care for their patient. These factors include clinical factor patient values, the available research evidence, clinical guidelines, their previous clinical experience and medico-legal implications [12]. Conventional complete denture prostheses have been widely used for the replacement of missing dentition [13]. Simpler methods of complete denture fabrication and technique

helps to reduce appointments and offer better compliance to the patients with respect to time, logistic and expenses [14]. Compilation of the various denture techniques in complete denture fabrication shows the evolution of denture techniques that led to reduced number of appointments, without compromising the outcome. Reduced appointments offer better compliance to the patients with respect to time, logistics and expenses [15].Over the past century, the technique of complete denture fabrication has evolved. Today, the most likely technique used in complete denture fabrication is the five appointment complete denture, which is the most suitable method of denture construction[16].Complete denture teaching, about four decades ago is composed of lectures, followed by clinical work, and later on preclinical complete denture curriculum was established[17]. Preclinical work includes demonstrations for the purpose of effective performance by the students[18]. Now, living in the fast-paced world, advanced learning method has been implemented such as video lectures with demonstrations and visual aids have been introduced[19]. Provided with advanced learning method with technology in dental education, studies show that there are still significant ineptness in complete denture fabrication even after graduation. This study sparked the need to improve competency of complete denture fabrication in undergraduates. Using better clinical materials, improving training methods and by making the technique simpler, competency in fabricating complete dentures can be accomplished. This survey conveys the proportion of the patients wearing the complete denture whether they are satisfied or not satisfied[20].Thus analysing this data will give us a clean knowledge on patients, their attitude, their knowledge towards dentistry and the skills of the dentist, and their knowledge towards dentistry.

Materials and methods

50 edentulous patients with their maxillary and mandibular complete dentures in use who were seeking prosthetic treatment for relining of their old dentures or the fabrication of new ones were selected. They were surveyed about their satisfaction with the treatment provided with their complete denture. The patients were also informed that their answers will be confidential. Then, the patients photograph along with their oral cavity have been captured for reference. It has been informed to the patients that their photographs captured is only collected for a personal data. The survey ended by collecting the patients' signature with date for the survey reference. This survey is now brought up by concluding with the results which are conveyed along with the statistics. It has also been discussed about the various

causes which affect the dentures such as halitosis, adaptation etc, and are briefly discussed in detail. This survey also depicts that the preparations of the complete dentures and the way of treatment towards the patients must be enhanced in such a way that the results are satisfactory and it is also satisfied to the patients.

Results:-

The results obtained were that almost 70% of the patients are satisfied with their complete dentures while the remaining are not satisfied. The statistics for the results are given below:

Discussion

Based on the facts of the survey and the above analysis clearly proves that women are more exhibited for the treatment of complete dentures than men. Further people with non vegetarian food habits are more likely to lose their teeth and going for complete denture. People in the age group of 55-60 and >65 are the ones who are affected mostly. Further, the number of visits is mostly 7 and >7 visits which needs to be addressed considering the age factor of the patients. While 50% of the patients are very much satisfied with their dentures provided, about 38% of the patients are not satisfied of which most of the women which is 71% of the total non satisfied category. Due attention and care to be improved while handling women patients for enhancement of satisfaction levels[11]. From the survey it is clear that most of the patients has visited their doctors seven times or more until their denture is comfortable to them. This means that lack of attention and concentration is the only cause for more number of visits[12]. Dentures also causes ulcerations and halitosis if it is not maintained properly. If the dentures are not maintained in a hygienic way, then microorganisms like bacteria, etc accumulates on the dentures and causes ulcerations[13]. Due to this there is progressive caries and this causes halitosis. Maintenance of the dentures is also important and it is not a difficult way. Placing the dentures in a compact and clean container which is filled with water cleans the dentures. Again, while replacing the dentures has to be replaced with fresh water[14-15].Thus hygiene also plays a very important role in maintenance of the dentures, where this also affects the outcome as well as the dental treatment. Patterns of tooth loss and retention are also changing. One of the key factors affecting the outcome of the treatment is the impression procedure involved in the fabrication of complete denture prosthesis. Various impression philosophies have been proposed over years by various authors, out of which the selective-pressure impression technique is most widely accepted by all since it produces a denture of good outcome[21]. Nine visit technique is the most time consuming complete denture fabrication method and was popular in 1950's. From this technique, complete denture fabrication started to evolve to simpler techniques. The nine visit denture technique consists of nine appointments, where the first two are diagnostic appointments and the remaining appointments are treatment appointments [22]. All these are techniques to improve the quality of the complete denture prosthesis which will even more satisfy the patients. Thus higher the quality, more the satisfactory rate is

assured.

Conclusion

It is been concluded that patients wearing complete denture are mostly satisfied with the treatment but some are not satisfied. This may be due to the personality traits and the behaviour and attitude of the dentist. Moreover, we can also see that there is some amount of dissatisfactory rate among the patients due to multiple number of visits, outcome of the denture and due to facial expressions. These can be corrected by the dentists by giving an excellent denture with good retention, stability and support and also with most esthetic prosthesis and with minimal visits which should have shorter appointments too which may enhance the satisfactory level for both the patients and dentists. Thus, it is expected that all the treatments provided to the complete denture patients in the future must be satisfactory.

A Survey on Consequences of Self-Medication Versus Prescribed Medication

Thejeswar EP [1], Anitha Roy [2], Thummala Bhagya Lakshmi [3]
Graduate Student, Professor,Department of Pharmacology
Senior Lecturer,Department of Pedodontics and Preventive Dentistry
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,
Saveetha University, Chennai, India

Abstract

Aim: To compare the pattern of self-medication and prescribed medication among the population in Chennai, India and to tabulate results and thereby creating awareness on population.

Materials and Methods:A questionnaire consisting of 15 questions were framed based on knowledge and usage of self-administered drugs as well as prescribed drugs. They were given to 100 people aged between 20-50 years without any gender difference. This study has a self-developed questionnaire, related to various aspects of self-medication and prescribed medication. A pre-tested interviewed administered questionnaire, with 17 questions was distributed to participants.

Results: Among 100 respondents, 72 respondents practice self-medication, while only 28 people choose prescribed the medication by a registered medical practitioner. Adverse reactions, lack of knowledge about dose, the frequency of administration and chances of taking the wrong medicine were the major drawbacks of self-medication reported. The frequently reported illness that prompted self-medication included Headache, Cough, Fever, Diarrhoea, and Acidity.

Conclusion: Usage of OTC drugs was highest among common population. Time consumption for consultation, financial crisis, availability of OTC drugs, the predictability of doctor's general prescription were the commonly mentioned reasons for self-medication. Hence, proper Education and awareness must be created to help patients decide on proper medications.

Key Words: *Awareness, Anti-biotics,Over the counter(OTC), Prescribed Drugs, Self-medication.*

Introduction

Self-medication is the use of drugs with therapeutic intent but without any professional advice or prescription. It has also been defined as the use of non-prescription medicines on their own initiative[1]. While on the other hand prescribed medication is the use of drugs with the help of medical supervision and prescription. Drug retail shops frequently serve as the public's first point of contact with the healthcare system[2].In India, pharmacists and pharmacy attendants play an important role in fostering self-medication among the public[3]. Self-medication can cause resistance to bacteria and may lead to the emergence of multiple resistant organisms that would be difficult to treat[4-7]. Studies on self-medication patterns and the prevalence of doctor prescribing in India shows an increasing number of patients developing resistance to the commonly used antibiotics. The most commonly available over the counter (OTC) medicines in Chennai are analgesics, non-steroidal anti-inflammatory drugs (NSAIDs), antihistaminic, vitamin supplements, tonics and cough and cold remedies. Although these medications are considered safe, their excessive use can lead to serious adverse effects.

In India, the Drugs and Cosmetics Act, 1940 (DCA), the Drugs and Cosmetics Rules, 1945 (DCR) regulates the import, manufacture, distribution, and sale of drugs and cosmetics. The “OTC” (over the counter) has no legal implications in India[8]. Hence “OTC Drugs” means drugs legally allowed to be sold “Over the Counter” by pharmacists, i.e. without the prescription of a Registered Medical Practitioner. Prescription-only drugs are listed in Schedules H and X of the Drug and Cosmetics Rules. Few drugs which are scheduled under G do not need the prescription to purchase but require the following mandatory text on the label: Caution: It is dangerous to take this preparation except under medical supervision[9]. In several studies it has been found that inappropriate self-medication can generally cause serious health hazards such as adverse drug reactions, and drug dependence[10].

Self-medication is now increasing as a component of self-care[11]. Unlike other aspects of self-care, self-medication involves the use of drugs and these drugs have the potential to do good as well as harm. Self-medication can save the time, may be economical but due to its improper use of correct dose, side-effects and interactions can lead to serious implications[12]. Therefore, the study was taken up to analyze the population at risk, in extend to various aspects of self-medication and prescribed medication and create awareness of the adverse effects among the participants.

Materials and Methods

A questionnaire consisting of 15 questions were framed based on knowledge and usage of self-administrated drugs as well as prescribed drugs and they were given to 100 people. This was a cross-sectional study and has a self-developed questionnaire, consisting of both open and closed end questions related to various aspects of self-medication and prescribed medication which were most commonly employed. The study population consisted of the common population of Chennai, between age group 20-50 years. People were explained about the aim and purpose of the study and concept of self- medication and prescribed medication were clearly explained and discussed with the them prior to the survey. The respondents were interviewed with the questions and corresponding answers were marked.

The questionnaire was in two parts. The first part had questions on demographic information of the respondents such as Name, age, gender, etc. The second part contained questions on core issues which dealt on direct questions such as reasons for self-medication, most common drugs used for self-medication, type of ailment treated through self-medication, factors influencing discomforts of self-medication practices and also knowledge about drug resistance. The questionnaire was framed in such a way for easy understanding and filling by respondents. The questionnaire was also backed by a moral interview. Some of the questions asked during the interview section were: do you think self-medication is a good practice? Do you think education will help reduce the incidence of self-medication?

The aims of our study were to obtain baseline data on self-medication and doctor prescribing drugsin Chennai city, obtain information on the factors influencing self-medication and Doctor prescribing medication. And to create awareness about the drug interactions, that can lead to drugs in implications and adverse effects, due to self-medication.

Data obtained from the questionnaire were coded, given sequential numbers and entered into the Statistical Package for Social Sciences (SPSS), version 16, software. The analysis was carried out using descriptive statistics and Prevalence of self-medication along with prescribed medication, among population were measured in percentages. Descriptive analysis was employed to present bar charts for appropriate results.

Results

One hundred respondents were covered during this entire study. The age distributions of the responders were between the age of 20 to 50 years. Out of one hundred responders (59) were male and the rest (41) were females. These 100 responders were from various professions from Chennai district selected

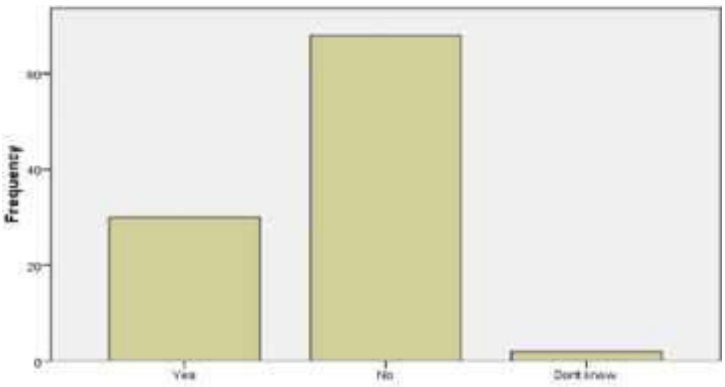
randomly for this survey. Coming to the results of administrating self-medication drugs in comparison to doctor's prescription drugs, when enquired about whether self-medication is good practice or not, (68%) responders accepted it's not good, while remaining (30%) responders said it is notbad, followed by 2% who doesn't know about it.[Graph 1]When we enquired them about Source of drug information, they responded that they gained knowledge from Doctors (48%), Internet (24%), friends (14%), Media (7%), Relatives (4%), while remaining (3%) learned from academic knowledge.[Graph 2]

According to the (28%) responders fever and cold are major reasons that demand them visiting doctors, followed by continuous headache (27%), and diarrhoea (24%). When they were enquired about completing the course of drugs that doctors prescribed (63%) responders said yes, while remaining (35%) does not finish the course of drugs which doctors prescribe is noted. (62%) responders said that they will visit the doctor for the second time, if the problem persists, while (38%) responded that, they will buy the same drugs over the counter, which was earlier prescribed by the doctors. From this survey we identified that confidence in self-medication (41%) was the main reason for administrating self-medication followed by, the financial crisis (35%), and time consumption (15%).

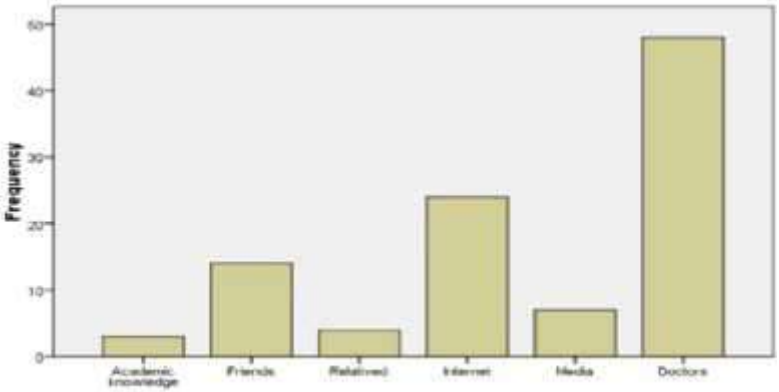
We also noticed (66%) responders were aware that drugs taken through self-medication have many disadvantages, while (33%) came up with a thought, it doesn't have any sort of adverse effects while remaining (1%) doesn't have any idea about it.[Graph 3] Even though self-medication has many side effects (54%) responders do not experience any side effects, while (31%) had severe side effects due to wrong self-medication, remaining (15%) were not sure about it. [Graph 4] When enquired about the safety of physician-prescribed medication in sequence to self-medicated ones, (93%) responders were absolutely sure that prescribed drugs are safe, while (7%) individuals said even prescribed drugs may not be safe always.

Interestingly (79%) responders said that they didn't experience any hospitalization due to adverse effects of self-medication, while (14%) went on hospitalization for further treatment due to its side effects, while (7%) individuals were not sure about it. According to the responders, the most commonly used over the counter drugs were Antibiotics (21%), Analgesics (21%), Anti-diarrheal (17%) followed by Anti-histamines (12%).[Graph 5] We also found that (63%) responders are not aware that Anti-biotic must be taken for complete dose due to its resistance, while just (32%) responders know about it, followed by (5%) individuals who don't even have any clue about it. We also identified the most common discomforts that people experience while administrating self-medication, they were Diarrhoea (32%), Allergies and rashes

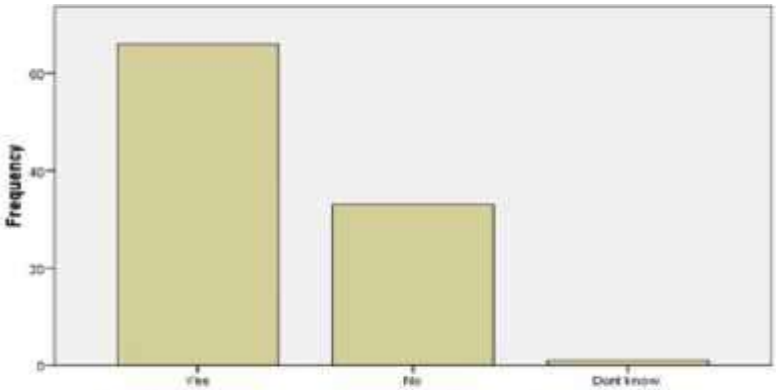
(21%), Constipation (18%), Nausea /Vomiting (14%), Headache (12%), and remaining (3%) doesn't have any discomforts.[Graph 6] when we enquired about their knowledge about drugs used for common problem, (47%) people responded that they have good knowledge, (36%) responded they have the average knowledge, while remaining (17%) have no idea about any drugs or drug names. Even after (47%) individuals said, they have good knowledge about drugs still (89%) individuals have no clue about combination drugs like H2 Blockers for NSAIDs, while only (11%) people knew about it and responded it's to counteract gastric irritation.



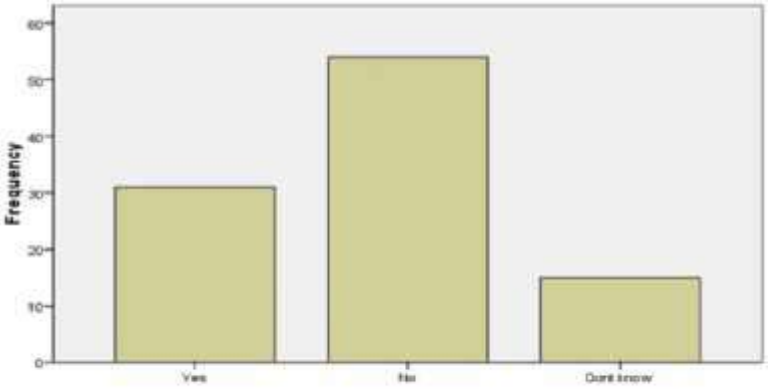
Graph 1 : Is self-medication a good practice?



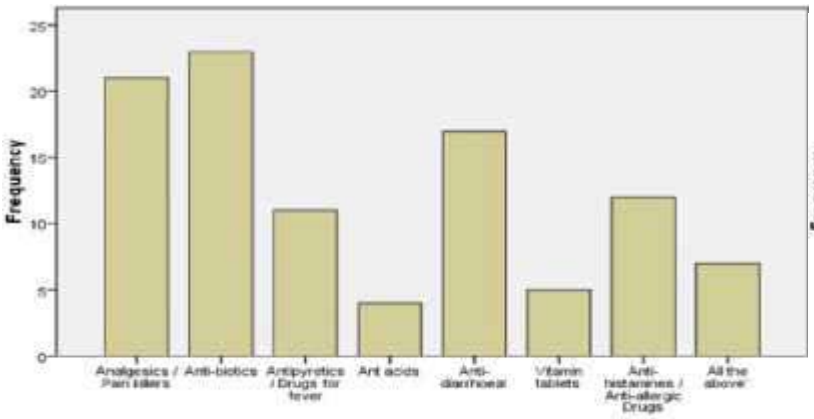
Graph 2 : Source of drug information?



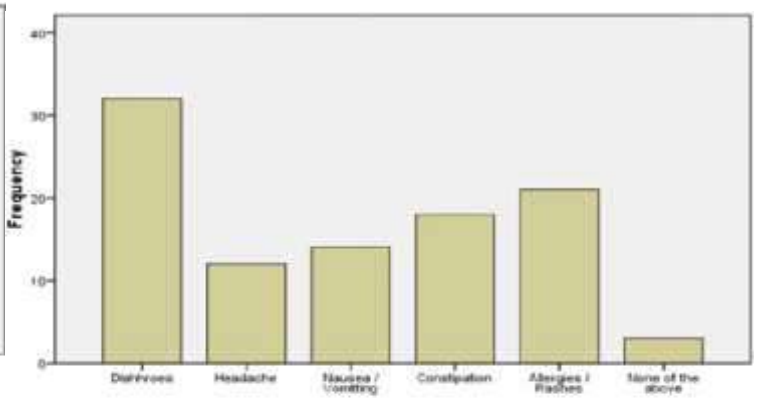
Graph 3 : Are you aware that drugs taken through self-medication have many disadvantages?



Graph 4 : Have you experienced adverse effects due to over the counter drugs?



Graph 5 : Most commonly used over the counter drug?



Graph 6 : Most common discomforts administrating self-medicated drug?

Discussion

Our study shows that majority of the responders were aware of OTC drugs and self-medication is widely practiced among them when compared to prescribed medication. Confidence in self-medication, a financial crisis etc, were some of the reasons for using OTC drugs. Anti-Biotics and Analgesics were the drugs most commonly used for self-medication. Male sex and age between 25- 40 years were associated with increased self-medication. Time consumption for consultation, the Financial crisis, availability of OTC drugs, predictability of doctor's general prescription were the commonly mentioned reasons for Self-medication. Diarrhoea and headache were the most common reasons for self-medication. We found Drugs especially anti-biotics were not taken for the proper course, which can lead to serious resistance in future. Education to help patients decide on the appropriateness of self-medication is required.

Self-medication is defined as the use of medication, whether modern or traditional, for self- treatment without the advice of physician (expert in the medical profession) either for diagnosis, and prescription. Of treatment. Experience from prior illness; advice from pharmacist, relatives, and friends play a major role in the self-medication. Out of total 100 responders, 59 were male and 41 were female. There was no statistically significant difference between males and females in regard to self-medication. A similar result was noted by Shahbaz Baig[13].According to one study, the most common reason of self-medication was not being in need, for a doctor in diseases widely seen and the most common form of obtaining medication was directly from a pharmacist without the prescription[14].

Prevalence of self-medication has been found among 81.5% individuals in a rural area in Maharashtra. More male patients used self-medication compared to females, contrary to data from Western reports[15]. A questionnaire-based cross-sectional study showed that prevalence of self-medication was about 88% among study participants. The frequency of self - medication is highly variable in different parts of the world; as

low as 45% in Turkey to as high as 94% in Hong Kong[16].

Some authors reported that previous experience was one of the major reason for self-medication besides unavailability of doctors and transport, ability to self-manage, an urgency to treat, assumption of better knowledge, lack of time and cost of treatment were the other contributing factors. But our study proves that they are not only the reason, but also, the confidence in self-medication drugs (41%), the financial crisis (35%), and time consumption (15%) were also the main reason for administrating self-medication.

In our study we enquired them about Source of drug information; they responded that they gained knowledge from Doctors prescription (48%), Internet (24%), friends (14%), Media (7%), Relatives (4%), while remaining (3%) learned from academic knowledge. Similarly, Advertisement in the newspaper and media as main sources followed by chemist shops. Therefore, it is necessary that pharmacist should take responsibility to avoid selling drugs without prescriptions.

Pharmacists play a valuable role in identifying, solving and preventing drug-related problems for achieving optimal patient outcomes and quality of life. Ambulatory based pharmacists have the responsibility to appropriate, effective and economical use of all medications, especially those therapies patients are self-selecting. Pharmacists should guide their customers to consult the physician before taking any medication by self[17-19].

Whenever a drug is prescribed to a person, he/she should be given instructions to the person's comprehensive levels so that it will be helpful for them to understand the impacts of it and also encourage them to adopt alternative methods to relieve their symptoms instead of using self-mediation there by preventing the ill effects of self-medication such as drug dependence, drug abuse, etc[20].

The economic barriers and familial competition has the potential to prompt an individual to indulge in self-medication[21].

The prevalence of medicine storage in room leads to practice of self medication. Analgesics and antibiotics are being the most common types of medicine present in residence[22].

self-medication was practiced with a range of drugs from the conventional anti-pains to antibiotics. Although the practice of self-medication is inevitable; drug authorities and health professionals need to educate students about the pros and cons of self-medication[23-24].

By taking inappropriate drugs the results can be two-fold. These drugs does not cure the actual pathology. It produces unwanted side - effects which affects the patient[25].

An antimicrobial is an agent that kills microorganisms or inhibits their growth. Antimicrobials can be grouped according to the microorganisms they act primarily against. They are ones which help in building up resistance[26].

Doctors and pharmacists play a very important role in creating awareness about self-medication by

educating the patients. Hence it is suggested that the public education is mandatory on the type of illness for self-diagnosis and its medication, along with an implementation of stringent rules and regulations on their use. It is also essential to highlight the dangers of OTCs on their misuse.

Conclusion

Our study shows that majority of the responders were aware of OTC drugs and self-medication is widely practiced among them when compared to prescribed medication. Confidence in self-medication, a financial crisis where the some of the reasons for using OTC drugs. Anti-Biotics and Analgesics were the drugs most commonly used for self-medication. Male sex and age between 25- 40 years were associated with increased self-medication. Time consumption for consultation, the Financial crisis, availability of OTC drugs, predictability of doctor's general prescription were the commonly mentioned reasons for Self-medication. Diarrhoea and headache were the most common reasons for self-medication. We found Drugs especially anti-biotics were not taken for the proper course, which can lead to serious resistance in future. Education to help patients decide on the appropriateness of self-medication is required. Self-medication is an alarming sign for society. It was analyzed that most of them were not aware of the drug, dosage, the frequency of administration and adverse reactions. While very little people were aware of these medications. Drugs, especially antimicrobials, which were not taken for the proper duration, can lead to serious resistance. Moreover, there are many drugs which are new to the market and many are banned due to side effects. Hence, proper education and awareness must be created to help patients decide on proper medications, which can save the lives from unnecessary complications.

Acknowledgement

We would like to express our gratitude to all the respondents for spending their valuable time to answer our questionnaire that helped us to successfully complete our study.

Abstract

Introduction: Medical emergencies can occur at any time in the dental office.Every health care providers should be aware of recognizing and handling medical emergencies in their respective workplace. All should be trained and frequently updated regarding aiding patient in emergency situations. The aim of this study is to determine the knowledge and preparedness of a dental practitioner to manage medical emergencies at their dental office.

Material and Methods: A self-administered questionnaire comprising of 10 questions was designed relating to medical emergencies that may occur in dental office, its prevention and management and was distributed to the practicing dentists in and around Chennai.

Result: A total of 150 dentists participated in this study. Of these 48 were BDS graduates and 102 were MDS graduates. Almost 134 have their working place in urban areas, 12 of them have working place in rural areas and 4 of them have their working place in both urban and rural areas. This study shows almost 97% of surveyed dentists enquire medical history including medication and allergy. Only 60% of dentists record vital signs of their patients. The study shows that only 72.6% were trained for management of medical emergencies in dental office and 94.6% of them responded that training to dentist for management of medical emergencies is important. It is found that only 68% of participants have been reported to be confident in handling medical emergency situation and about 27% have been faced with medical emergency for past 12 months

Conclusion: Dentists being members of the healthcare profession, should be prepared to deal with medical emergencies which may arise at their workplace. A better knowledge of medical emergencies is essential for further development and professional care for people with various medical complications. This will ensure the provision of better and safer dental healthcare services for the population.

Key Words: *dental office, adverse effects, drugs, vital signs, knowledge*

Introduction

A medical emergency is generally termed as an acute injury or illness that poses an immediate risk to a person's life or long-term health. Medical emergencies can occur at any time in the dental office.[1] Medical emergencies can be alarming to any clinician but these situations and can be prevented if proper preparations are made.[2] Effective management of medical emergencies in the dental office are ultimately the dentist's responsibility. Lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legal action.[3] Fear and anxiety in patient seeking dental treatment may cause measurable metabolic changes, which make these patients prone to such emergencies. The chance of medical emergency increases with administration of anesthesia and medication, virtually all of which are known to have adverse reactions [4]. Most dental procedures are performed under local anesthesia.[12] The primary prevention by giving prescription may influence their patient's health.[13] Anaphylaxis is defined as a serious allergic reaction that is rapid in onset and may cause death.[14] The worst manifestations are cardiovascular collapse, bronchospasm and laryngeal edema.[15]. General Adverse effects include localized reactions like minimal to moderate redness was reported and central nervous system manifestations.[16] A good step in making ready for clinical emergencies is the acquisition of emergency supplies. The circle of neighboring physicians should choose emergency drugs and device that reflect the spectrum of their office's expected emergencies.[17] The most crucial element of nearly all medical emergencies in the dental workplaces is to save patient, or accurate, provide adequate oxygenation to the brain and heart.[18] Therefore, the control of all clinical emergencies ought to ensure that oxygenated blood is being introduced to those important organs. That

is constant with basic CPR, with which the dentist must be in a position.[19] A successful prevention relies upon at the assessment of a patient's history and physical situation as well as suitable treatment adjustments.[20] The aim of this study is to determine knowledge and preparedness of dentists to manage medical emergencies at their dental offices and assess the availability of medical emergency drugs and equipments.

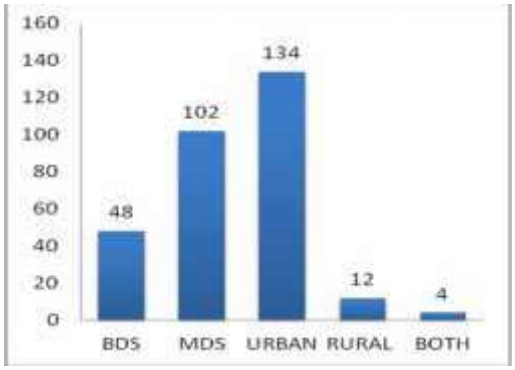
Material and Methods

This study was conducted to determine the awareness on medical emergency in dental office among practicing dentists. This study was conducted among dentists practicing in and around Chennai. A valid questionnaire of 10 was designed which was inclusive of both open and close ended questions relating to medical emergencies that may occur in dental office, its prevention and management. All questions were given two options (Yes / No**)**. The questionnaire was distributed among dentists in and around Chennai, who were willing to participate in the study. This is self reported questionnaire which takes 10 minutes for completion. The participant of the study includes dentists who were undergraduates, postgraduate with clinics in urban or rural areas or clinics in both urban and rural areas. Questionnaires were manually checked for completion of data. All data were entered in data entry form. The analysis of data was done and percentage calculation of the collected data was done with simple mathematical calculations.

Result

A total of 150 dentists participated in this study. Of these 48 were BDS graduates and 102 were MDS graduates. Almost 134 have their working place in urban areas, 12 of them have working place in rural areas and 4 of them have their working place in both urban and rural areas (graph 1). This study shows almost 97% of surveyed dentists enquire medical history including medication and allergy. Only 60% of dentists record vital signs of their patients. The study shows that only 72.6% were trained for management of medical emergencies in dental office and 94.6% of them responded that training to dentist for management of medical emergencies is important. It is found that only 68% of participants were reported to be confident in handling medical emergency situation and about 27% have faced with medical emergency in their dental office for past 12 months (graph 2).

Graph 3 shows that among surveyed dentists 41 of them have no emergency drugs and equipments and only 109 have been reported to have emergency drugs and equipments. Adrenalin, glucose are the most commonly stocked drugs and 70% of them have AMBU bag and 38% of them have oxygen cylinders. Other drugs and equipments reported are ammonia (51%), nitroglycerin (78.6%), epinephrine (79%), oxygen (89%), antihistaminic drugs such as phenramine maleate, diphenhydramine, chlorpheniramine (80%), bronchodilator such as salbutamol, albuterol (76.6%), atropine (47%), aspirin (53%), steroids such as hydrocortisone, dexamethasone (70.6%), tranhexaminic acid (3%), magill



Graph 1: Distribution of participants based on graduation and working place

forceps, laryngoscope, oropharyngeal tube (1%), I.V cannula (6.6%). Chart 1 shows that the most common medical emergency reported in dental office faced by participants is syncope (52%). Other medical emergencies faced in dental office reported are hypertension (5%), respiratory depression (2%), hypoglycemia (14%), seizure (14%), hypersensitivity (2%), shock (2%), bleeding disorder (7%), and angina (2%).

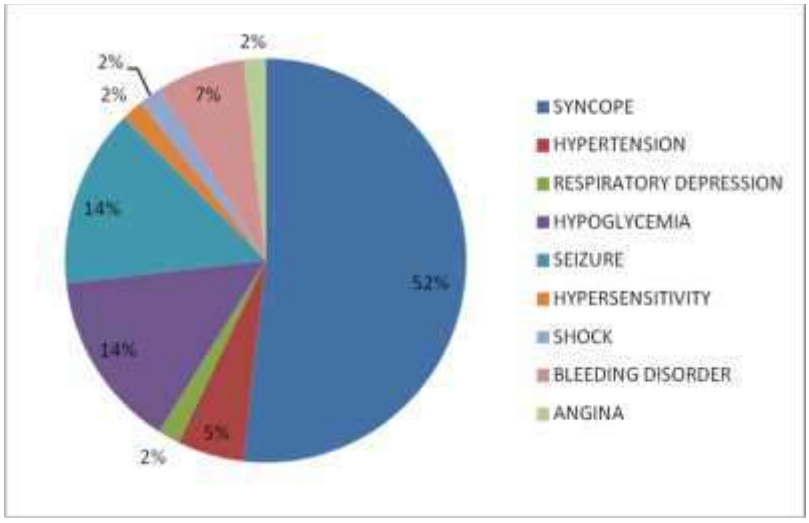

Graph 3: Availability of medical emergency drugs and equipments

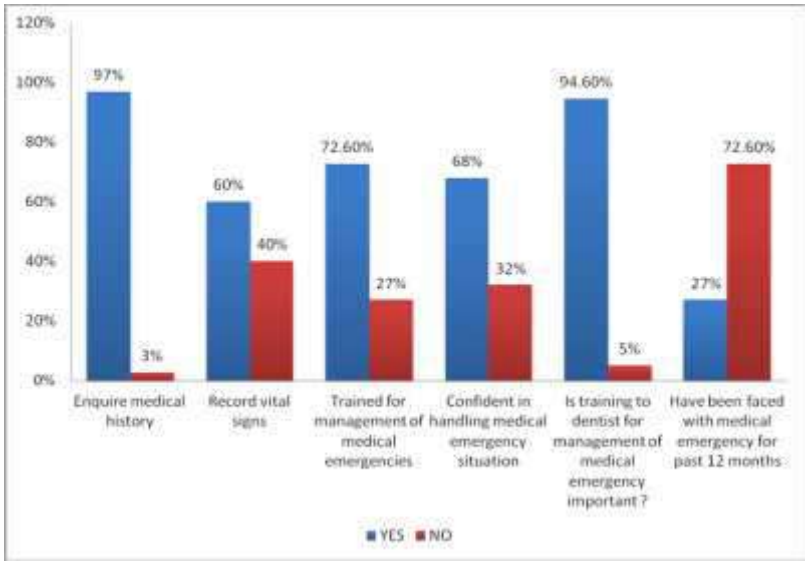

Chart 1: Medical emergencies reported by dentists in their dental office

Discussion

This study was conducted to assess the knowledge and preparedness of dentists to manage medical emergencies at their dental office. In this study, it is determined that only 72.6% of surveyed dentists are trained for management of medical emergencies, which is comparatively higher than the one reported by Gupta et al in which only 42.1% dentists were reported to be trained.[4] It is found that 94.6% of dentists responded that training to dentists for management of medical emergency is important, this is comparatively less than Praveen et al who reported 97.1% felt training is important.[2] In this study it is found that 97% of surveyed dentists enquire about medical history including medication and allergy which is similar to that of Shwetha et al.[5] About 60% of dentists record vital signs but most of them record only blood pressure and pulse in needed situation. It is important to enquire about medical history, record vital signs because it may give a clue for possibility of occurrence of medical emergency at dental office. It is found that only 27% of them have experienced medical emergency during their practice. The experience reported only within 12 months duration was enquired as it may be easy for the dentists to recall the situation. Among the surveyed dentists only 68% of them are confident in managing medical emergency situations in dental office which is higher than compared to the survey done by Maisa et al. According to their survey only 41% of the surveyed dentists were confident in handling medical emergency situation.[6] Even though 72.6% of the dentists were reported to be trained only 68% of them are confident in handling medical emergency situation. This may be due to improper training to the dentists, short duration programs, etc. The 27% of dentists who have experienced medical emergency situation at their dental office were enquired about the common medical emergency situation they experienced.

The most commonly reported medical emergency was syncope of 52% , seizure disorder and hypoglycemia 14%, and other emergency situations such as hypersensitivity, shock, angina, respiratory distress, hypertension, bleeding disorders were reported to be occurring less than 10%. Similar results were obtained in study done by Praveen et al [2]. In study

done by Laurent et al[7] and Gbotolorun OM et al,[8] syncope was reported to be the common medical emergency situation encountered by dentists.

On enquiring about availability of medical emergency drugs, among the surveyed dentists, about 38% of them reported to have no drugs and equipments available in their dental office. This is higher when compared to Chapman's study in which 14% of dentists reported of not having any emergency drugs and equipments.[9] Adrenalin and glucose are the most commonly stocked drug and 70% of them have AMBU bag, 38% of them have oxygen cylinders. Other drugs and equipments reported are ammonia (51%), nitroglycerin (78.6%), epinephrine (79%), oxygen (89%), antihistaminic drugs such as pheniramine maleate, diphenhydramine, chlorpheniramine (80%), bronchodilator such as salbutamol, albuterol (76.6%), atropine (47%), aspirin (53%), steroids such as hydrocortisone, dexamethasone (70.6%), tranexaminic acid (3%), magill forceps, laryngoscope, oropharyngeal tube (1%), I.V cannula (6.6%). According to Amirchaghmaghi et al, nitroglycerin was reported to be commonest drug and syringe and I.V cannula were reported to be commonest equipment available in dental office.[10]

Even though the incidence level is reported to be increased when compared to studies done previously, the reported levels are still low and should be improved. It is important for all dentists to attain knowledge about management of medical emergency. It is suggested that training to dentists about management of medical emergency should be considered seriously. Many awareness programs, training sessions, long duration training programs should be done. The training must be provided in such a way that the dentists are confident in handling any medical emergency situation during their practice. Proper training, better knowledge of management of medical emergencies will provide confidence for a dentist to handle it. By properly equipping the office, educating their assistants and staffs, the dentist can ensure that their patients receive essential care in office emergencies.[11] This will provide a fortified dental care for the population.

Conclusion

To conclude, Dentists being members of the healthcare profession, should be prepared to deal with medical emergencies which may arise at their workplace. Dentistry in India has made tremendous progress in different subspecialties of dentistry. A better knowledge of

medical emergencies is essential for further development and professional care for people with various medical complications. This will ensure the provision of better and safer dental healthcare services for the population.

Abstract

Introduction: Federation DentaireInternationale have formulated criteria for quality assessment of restorations and serve as a guidelines to determine if a restoration needs refurbishment, repair or replacement. Refurbishment is referred as a minimal intervention such as polishing or contouring when no additional material is placed. Repair is a minimal intervention that requires additional material to be placed with or without a minimal preparation in the restoration or dental tissues. Clinical criteria will group the aesthetic, biological and functional categories of restoration for clinical evaluation procedure.

Materials and Methods: A pre-piloted questionnaire was distributed amongst a group of 100 dentists randomly selected from all the departments of the dental college. Dentists were surveyed in relation to their knowledge about FDI criteria and advantages in assessing a restoration using FDI criteria.

Result: 96% of participants were aware of FDI criteria for evaluating the restorations and 4% knew both Ryge and FDI criteria. We found that more that half population are not trained for assessing the restorations. 80% population believe that criteria should be followed for evaluation of restoration which gives a positive scope for this system.

Conclusion: The FDI clinical criteria and scoring system is very efficient system for evaluation of direct and indirect restorations. With the limitations of the study, we conclude that by proper training and calibration this criteria can be applied not only by the researchers but also by dental students and general practitioners for quality assurance purpose of replacement andrepair of dental restorations.

Key Word: *FDI criteria, Dental restorations, Replacement, Quality, Training*

Introduction

Dental restorations are the one most commonly done treatment in dentistry. Assessment of the dental restoration is important for quality assurance in dental office[1]. Significant step has to be taken to improvise the knowledge about the dental restoration. In 2007, a new clinical criteria were approved by theFDI to assess restoration quality. This article on restoration evaluation was published in the journal of adhesive dentistry[2] and also in the journal of clinical oral investigation[3] for the evaluation of dental restoration. This standard criteria should be utilised when the restorative materials and operative techniques are to be investigated clinically. Restored material should be assessed whether it can be maintained or undergo refurbishment, repair or any replacement. One study has compared the FDI criteria and the traditional United States Public Health Service (USPHS) which is also called as Ryge criteria for the evaluation of restorations in deciduous teeth[4]. In that study it was concluded that FDI is more sensitive for identifying difference in deciduous composite resin restorations[5]. In 2008 a tool called e-calib was introduced to facilitate both training and calibration of new FDI criteria. The cases will be selected randomly with high quality photographs. Scoring in percentage is done to evaluate correct response. This helps a practitioner to improvise their knowledge of assessing the restorations. A good quality restoration requires many clinical considerations. FDI criteria gives many strategies to identify the cause of failure[6,7]. Applicationof FDI criteria improves the standards of clinical practice and dental care[8-11].

FDI Criteria

Aesthetic Criteria

1. Surface luster
2. Staining: (a) surface and (b) margin
3. Colour match and translucency
4. Aesthetic anatomical form

Functional Criteria

1. Fracture of material and retention
2. Marginal adaptation
3. Occlusal contour and wear

4. Approximate anatomical form: (a) contact point and (b) contour
5. Radiographic examination, where applicable
6. Patient's view

Biological Criteria

1. Postoperative sensitivity and tooth vitality
2. Recurrence of caries, erosion, abfraction
3. Tooth integrity
4. Periodontal response
5. Adjacent mucosa
6. Oral and general health

For all three groups, the following gradings are used for evaluation:

1. Clinically excellent/very good
2. Clinically good
3. Clinically sufficient/satisfactory
4. Clinically unsatisfactory
5. Clinically poor

Table 1: Questionnaire

Age:
Sex:
Speciality:
Years of experience:
1.Are you aware of clinical criteria for dental restorations
a)Yes b) No
2. Among the following which clinical criteria have you read
a)FDI Clinical criteria
b) Ryge criteria
c) none of the above
3. Do we need strict/universally accepted clinical criteria for evaluation of
dental restorations.
a)Yes b)No

If yes why?
a)Easy communication
b)Standardisation
c)Easy follow up
d)Treatment plan
4. Have you undergone training for evaluation of dental restoration
a) yes
b) no
5.Clinical evaluation of restored material should be done
a) on the day of restoration
b) after one week
c) after 6,12 and 18 months
6. Assessment of the restoration is done through
a) black and white photographs
b)Colour photographs
c)Radiographs
7. The clinical assessment influence the treatment plan
a)strongly agree
b)Agree
c) disagree
d) strongly disagree
8. Is it possible to train the undergraduate students to assess restoration based on the FDI criteria.
a) yes
b) no
9.Are you practising FDI criteria

If yes, reasons for practising the FDI criteria.
a) reliable
b) quality
c) easy
d) increase restoration longevity
e)treatment plan
f) faster than other criteria
10. Are you practising FDI criteria
If no, reasons for not practicing the FDI criteria
a)Time consuming
b)patient cooperation
c)lack of knowledge and training
d)not interested

Scoring the Dental Restoration

Restoration is judged as clinically as unacceptable, then the reason has to be recorded for the failure and it must be decided whether the restoration goes for repair or replacement. Not all restorations with score 4 be replaced. Localised defects with sufficient clinical access can be repaired like gaps which can be sealed, adding new material to chipped fractures, and veneering of stained areas of the restorations, etc. Repaired restorations are scored as relative failure and replaced restorations are scored as absolute failure. Most commonly score 5 clinical results gives bad results than score 4, but that is not inevitable. Score 4, and consequently the possibility for repair, depends more on whether it is accessible for repair or not. A repair is considered to be minimally invasive approach that implies the addition of restorative material after the defect is explored with or without involvement of material placement. Refurbishment is referred as a minimal intervention which leads to contouring , polishing or the application of glaze or adhesives. To take into consideration the extent of a clinical defect or observation in relation to the entire restoration or to record the exact location of the defect, there is a semi quantitative Clinical Evaluation which is recommended. Final rating of a particular restoration is only evaluated after completion of the assessments of the final scores for aesthetic, biological, functional aspects of restoration. More severe the score it will prevail. Whenever a restoration receives a score of 4 or 5 independent of the

specific criteria below, it should be recorded as a failure, but it is not necessary that all failures call for replacement of the entire restoration.

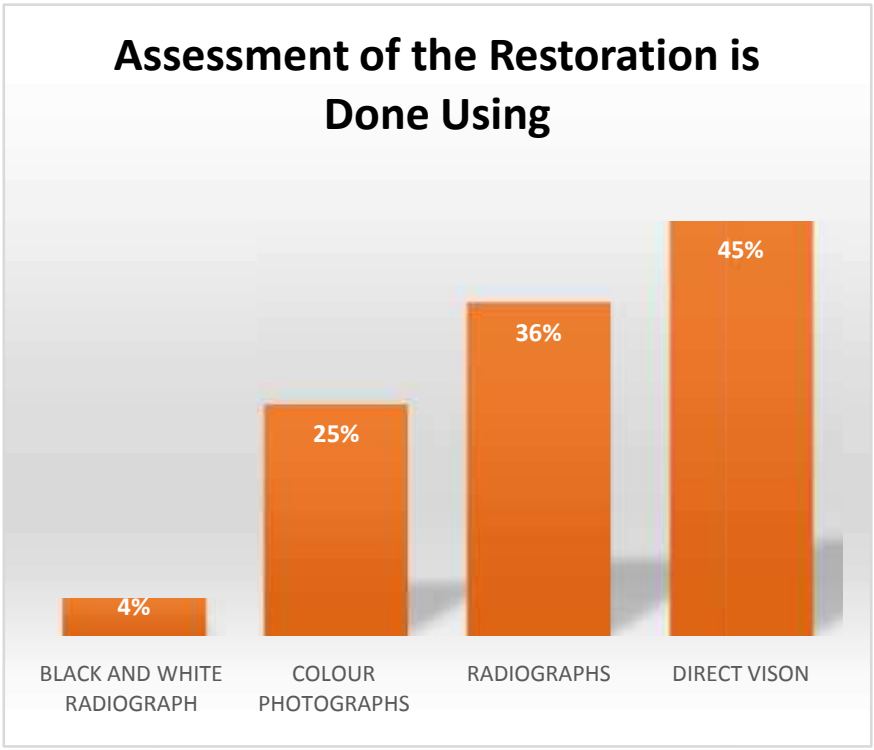

Figure 4: Restoration Assessment

Figure 5: Duration left to evaluate a restoration

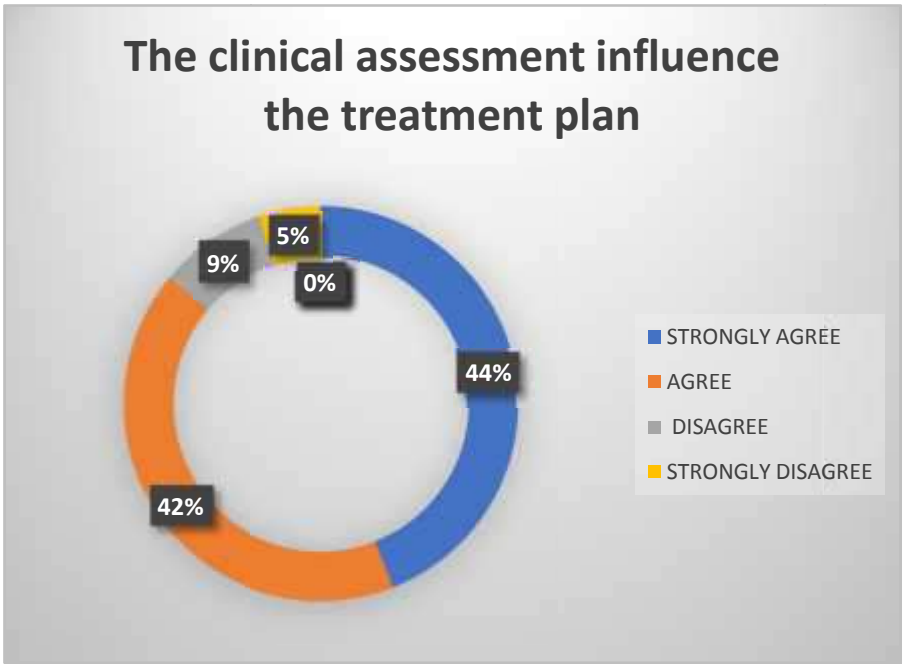

Figure 6: Clinical assessment on influencing treatmentplan

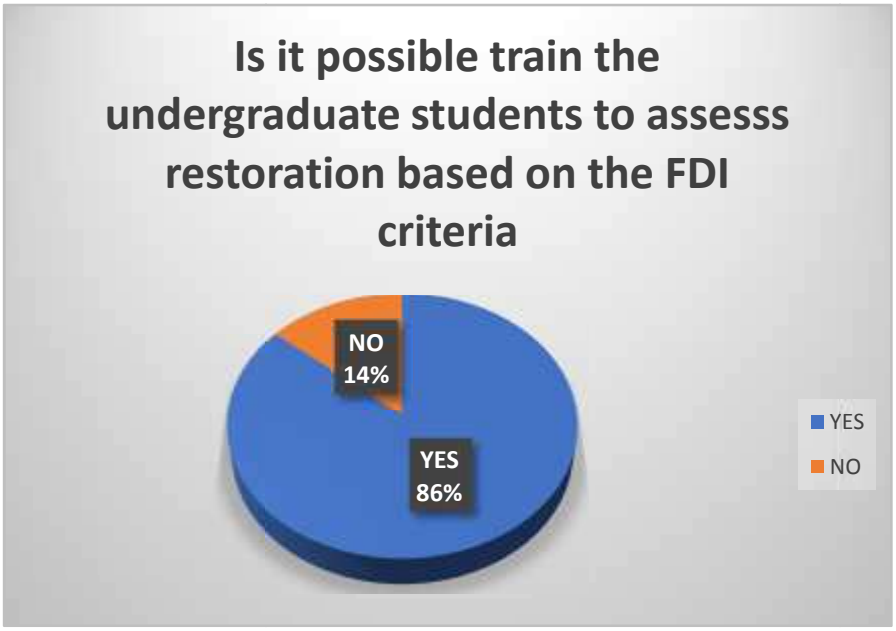

Figure 7: Possibility of traing an undergraduate

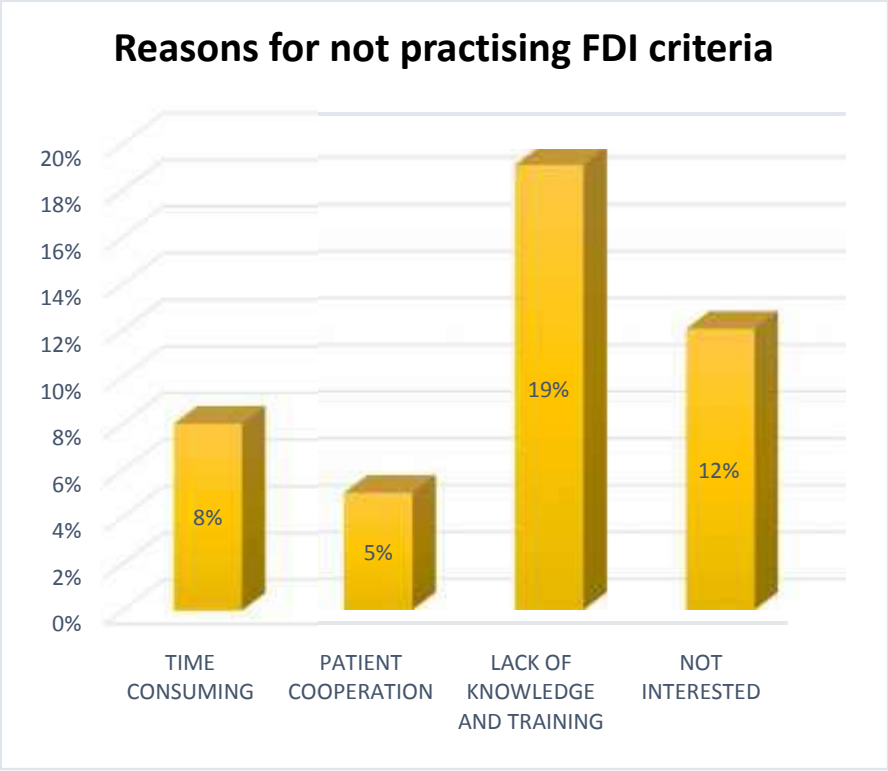

Figure 8: Reason for not practising criteria

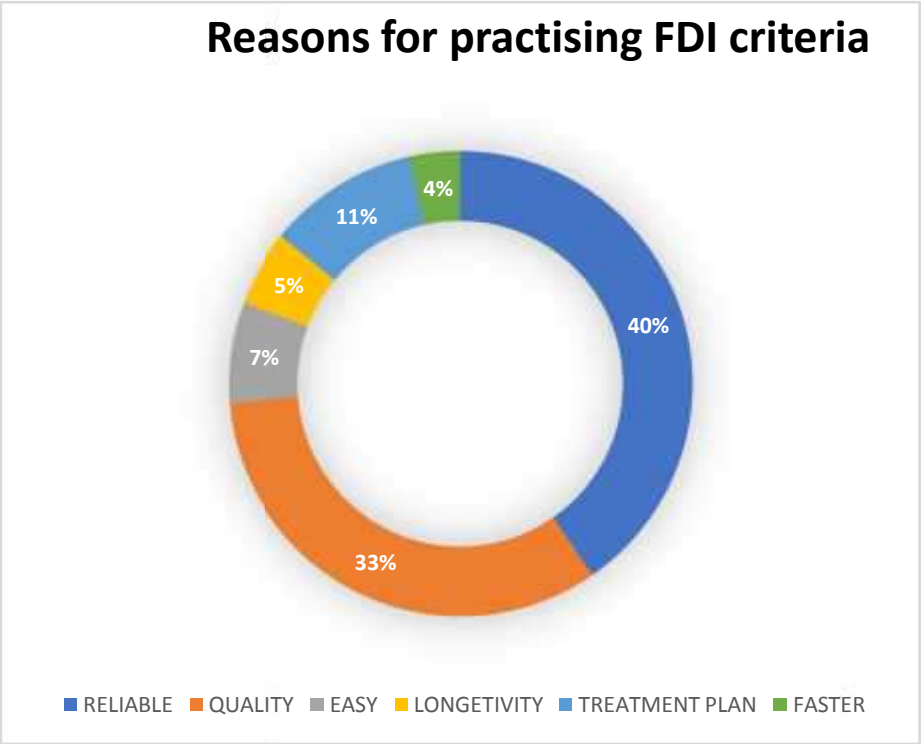

Figure 9: Reason for not practising criteria

Total respondents n=100 completed the questionnaire. Among 100 dentists 53 are females and 47 are males. Minimum year of experience of dentists has been surveyed to be 1 year and maximum is 8 years.63% of the dentists have 3 years of experience.

51%of respondents were aware of FDI criteria, 45% with Ryge and only 4% were well versed with both (Figure1). Among 100 dentists 58 were trained to assess the restoration (Figure2). 84% of participants favoured universally accepted clinical criteria for evaluation(Figure 3) . Most of the dentists shared their opinion that evaluation of dental restoration should be done after 6,12 and 18 months only(Figure5). 86% of dentists reported that it is possible to train the undergraduate students to assess the restorations(Figure7).

45% of the dentists prefers assessment of restoration through direct vision, 35% through radiographs,25% through colour radiographs and 4% through black and white photographs(Figure4). 86% of respondents feel that clinical assessment influence the treatment plan(Figure6). Reliability of FDI criteria is responsible for dentist adapting it for restoration evaluation.

Discussion

Dental caries is the most common oral health disease in developing countries[11]. The conservative approach of treating dental caries is dental restorationsMany studies have demonstrated that major work of the dentist is re-restoration of previously restored teeth. The estimations of annual expenditure of replacement dentistry were 5000 million dollars in USA[12,13].600 million Euros in Netherland[14], 100 million Great Britain pounds in UK[15]. To avoid premature replacement of restoration, FDI clinical criteria and scoring system for the evaluation of both direct and indirect restoration have been introduced.

This study is to evaluate the knowledge of dentists in assessing the dental restoration. Knowledge of clinical criteria is important, which plays a role in treatment plan and in turn success of the procedure. Moreover the dental material used and the technique can also be assessed. 86% of participants were aware of FDI criteria for evaluating the restorations and 4% knew both Ryge and FDI criteria. We found that more than half respondents are not trained for assessing the restorations. 80% respondents strongly want criteria to be followed for evaluation of restoration which gives a positive scope for this system. Most of the dentists answered that restoration is assessed through direct vision which is true but even colour photographs can help in assessing which is seen in e-calib trainings but 36% and 4% population failed to give correct answer by choosing radiographs and black and white photographs which cannot currently help in assessment. We found that about 86% of participants completely agree that standard clinical criteria helps in treatment plan.

Recent studies in 2016 by Thomas marquillier et al. shows that 16.3% of the studies used FDI criteria and the percentage of using this criteria has increased from 4.5% in 2010 to 50% in 2016 and the most employed criteria was marginal adaptation and the least in the study was surface luster[16]. Another study by Reinhardhickle reported that a grouping of esthetic, functional and biological categories have simplified the clinical evaluation procedures[17]. On other hand a study by s Deepak et al. stated that FDI criteria is not sensitive enough to determine the minor changes like proximal contact tightness[18] instead there are better instruments which was designed by loomans et al. at university of technology at Delft, Nertherlands[19]and other instrument by investigators at university of Tokushima, Korea[20]. It is surprising to know that even though FDI criteria has lot of advantages it remains as a hurdle to practice it with ease. Some of the dentists feels it is time consuming or have limited

knowledge. The dentists also responded that FDI criteria can be easily taught to students.

Conclusion

The FDI clinical criteria and scoring system is very efficient system for evaluation of direct and indirect restorations. It is a well- structured and flexible criteria, which can be selected and adjusted according to the needs of the investigator. With the limitations of the study, we conclude that by proper training and calibration this criteria can be applied not only by the researchers but also by dental students and general practitioners for quality assurance purpose of replacement and repair of dental restorations.

Abstract

Introduction: The use of rubber dam is an excellent means of providing infection control during dental treatment by reducing bacterial contamination of prepared cavities, root canal system and reducing the transmission of infections between dentist and patient. Rubber dam is recommended for various restorative and endodontic procedures.This study was conducted to evaluate the attitude towards the use of rubber dam in clinical practice by students of a private dental school.The rubber dam is considered to be the greatest benefit to patients safety.

Materials and Method: A prepiloted questionnaire was prepared and distributed to 120 juniorstudents in private dental college. The questionnaire included various aspects on rubber dam use in dental procedures like indications, advantages difficulty in application. Statistical analysis done by using chi-square test and used for comparison of qualitative data ($p<0.05$) was estimated.

Results: 79.3% males accepted that rubber dam is adequate usage in dental school training and 20.7% opinionated that training is inadequate. 81.7% females accepted it is adequate and 18.3% accepted it is not.

Conclusion: The response to the questionnaire was mixed amongst the participants which was statistically significant. It is very much necessary to increase the awareness amongst practitioners to the benefits of a rubber dam usage by means of continuing education. Rubber dam will make dentistry much faster, easier and safer for both practitioners and patients.

Key Words:*Rubber dam, Clamp, Dental school, Restoration, Clinical standard*

Introduction

Rubber dam has been considered as an ideal method to control infection in the oral environment. It was introduced in dentistry in 1864 by S.C. Barnum, a Newyorkcity dentist. To provide isolation, to create an aseptic area and to prevent the ingestion of irrigants rubber dam application has been in practice for more than 150 years[1]. It offers various advantages such as dry, clear operative field, improved access and visibility, soft tissue protection and retraction during operative procedures, prevention of infection transfer and aspiration of instrument and materials and also for the patients who are sensitive to gag reflex[2,3]. Although universally accepted, dentists fail to use it in their daily practice[4]. . It has been widely recommended in developed countries[5,6]. It is consider to be an essential component in modern restorative dentistry[7,8]. Many dental schools emphasizes all students to use to the rubber dam during all operative procedures, the matter of concern is whether they strongly adopt using rubber dam throughout their dental practice. In spite of all recommendation its wide range of functions is often overlooked by dental practitioners[10,11,12]. Literature shows rubber dam in pediatric dentistry has been on use for more than 100 years[13]. The present questionnaire based survey aimed to assess students perspective on the use of rubber dam in routine dental practice.

Materials and Methods

A prepiloted questionnaire was prepared and distributed to 120 interns and post graduate students of private dental collage, Chennai. The questionnaire included various aspects on rubber dam use in dental procedures like indications, advantages difficulty in application. Statistical analysis done by using chi-square test and significance ($p<0.05$) was estimated.

Table 1: Questionnaire

1. Gender
male female
2.Training in dental school on the use of rubber dam
a) Adequate b) Inadequate
3. Greatest advantage offered by the rubber dam
a) Provision of isolation and an aseptic working area

b) Preventive of swallowing or aspirating materials
c) Preventing the ingestion of irrigants
4. What is the major factor that makes rubber dam application difficult?
a) Selection of clamp and its adaptation
b) Placement of rubber dam
c) Placement of the frame
5. Rubber dam is not a helpful adjunct because
a) I experience difficulty during application
b) I believe that it consumes time
c) I believe patients do not like it.
6. Is patient explained about need to use rubber dam?
a) Yes
b) No
7. Patient opinion on rubber dam application
a) Doctors benefit
b) Their benefit
c) Both
8. Patient experience with rubber dam
a) Pleasant
b) Uncomfortable
c) Painful
9. Do you ask your patient whether they have latex allergy prior to rubber dam usage
a) Yes
b) No
10. Patient preference on rubber dam to be during next dental treatment
a) Yes
b) No
11. Which procedure you feel it is mandatory to use rubber dam
a) Amalgam filling
b) Composite resin filling

c) Root canal treatment
d) All the above
12. Your most common reason not to use rubber dam for restorative procedure is
a) Time and cost
b) Inconvenience
c) Patients refusal
13. Do you feel that the rubber dam has any effect on your restorative procedures
a) Yes
b) No
14. A higher clinical standard is possible when restorations are placed under a rubber dam
a) Yes
b) No
15. Restorations placed under the rubber dam have greater longevity than those placed without
a) Yes
b) No
16. You believe rubber dam prevents contamination
a) Yes
b) No
17. Do you use rubber dam in pediatric patients
a) Yes
b) No
18. Time taken to apply rubber dam
a)Seconds b)Minutes
19.Do you use of rubber dam in private practice following graduation
a) I strongly believe that it is helpful tool
b) I only use it because I am obliged to
20. Following graduation
a) I intend to use the rubber dam during all the procedures required
b) I intend to use only during restorative procedures
c) I intend to use it only during root canal treatment

d) I will never use it.

Results

Total respondents were 120 students. Among 120 students there were 29 males and 91 females. Among them 79.3% males accepted that rubber dam is adequate usage in dental school training and 20.7% opinionated that training is inadequate. Among females 81.7% accepted it is adequate and 18.3% accepted it is not.

Table 2: Answers given by the students regarding the adequacy of rubber dam

Training in dental school on the use of rubber dam	Gender						P-VALUE
	Male		Female		Total		
	N	%	N	%	N	%	
Adequate	23	79.3	75	82.4	98	81.7	0.706
Inadequate	6	20.7	16	17.6	22	18.3	
Total	29	100.0	91	100.0	120	100.0	

In terms of advantage offered by rubber dam about 63.3% with statistical significance(P=0.037) mentioned that provision of isolation and an aseptic working area as a top ranked benefit and 29.2% of students mentioned that prevention of swallowing or aspirating materials as another advantage. 88.3% students agreed that rubber dam prevents contamination but 11.7% said it is not helpful in preventing contamination.

Table 3: Answers given to the questions based on utilization of rubber dam usage

Questions	Options	Total		P- VALUE
		N	%	
Greatest advantage offered by the rubber dam	Provision of isolation and an aseptic working area	76	63.3	0.037
	Prevention of swallowing or aspirating materials	35	29.2	
	Preventing the ingestion of irrigants	9	7.5	
	Total	120	100.0	P-VALUE 0.995
Believe rubber dam prevents contamination	Yes	106	88.3	
	No	14	11.7	
	Total	120	100.0	

Regarding difficulties faced during rubber dam usage, 44.2% students reported that selection of clamp and its adaptation as their difficulty and 41.7% students felt difficulty in placement of rubber dam. Only 14.2% had difficulty in placement of the frame .40% students had an opinion that rubber dam is not a helpful adjunct because patients do not like it. 38.3% felt that it consumes time (p=0.009).45.8% students did not use the rubber dam due to patients refusal.

Table 4: Opinion of students based on the difficulties faced during Rubber Dam usage

Questions	Options	Total		P- VALUE
		N	%	
Major factor that makes rubber dam application difficult	Selection of clamp and its adaptation	53	44.2	0.771
	Placement of rubber dam	50	41.7	
	Placement of the frame	17	14.2	
	Total	120	100.0	
Rubber dam is not a helpful adjunct because	Difficulty during application	26	21.7	0.009
	It consumes time	46	38.3	
	Patients do not like it	48	40.0	
	Total	120	100.0	
Most common reason not to use rubber dam for restorative procedure is	Time and cost	26	21.7	0.304
	Inconvenience	39	32.5	
	Patients refusal	55	45.8	
	Total	120	100.0	

73.3% students (p=0.022) felt that patient should be explained about rubber dam usage. 42.5% of respondents felt patients feel rubber dam is used for both doctors and patients benefit, 35% opinioned it is only for dentists benefit. 62.5% students were of opinion that patient find wearing rubber dam to be uncomfortable. 73.3% of students questioned the patients regarding latex

allergy prior to rubber dam usage. 70.8% (p=0.002) students reported that patients will never prefer wearing the rubber dam next time.

Table 5: Answers given by the students regarding Rubber Dam usage on Patients

Questions	Options	Total		P-VALUE
		N	%	
Patient explained about need to use rubberdam.	Yes	88	73.3	0.022
	No	32	26.7	
	Total	120	100.0	
Patient opinion onrubber dam application	Doctors benefit	42	35.0	0.730
	Their benefit	27	22.5	
	Both	51	42.5	
	Total	120	100.0	
Patient experience with rubber dam	Pleasant	10	8.3	0.451
	Uncomfortable	75	62.5	
	Painful	35	29.2	
	Total	120	100.0	
Do you ask patients whether they have latex allergy prior rubber dam usage	Yes	88	73.3	0.187
	No	32	26.7	
	Total	120	100.0	

Patient preference on rubber dam to be used during next Dental treatment	Yes	35	29.2	0.002
	No	85	70.8	
	Total	120	100.0	

Majority of the students told that they do not use rubber dam on pediatric patients (78.3%). 50% of students reported that they use rubber dam because it is a helpful tool remaining do it as an obligation. Following graduation 44.2% students preferred rubber dam only for restorative procedures and 22.5% for all the dental procedures. 15% students said that they will use it only during root canal treatment. 18.3% said they will never use rubber dam following their graduation.

Discussion

Conducting a survey on a topic without external influence is quite difficult as stated by Hill and Rubel[9]. As students are in their learning phase they may be tempted to give what is perceived as correct answer instead of an honest answer.Majority of the participants thought the rubber dam usage training in dental school is adequate. It is surprising to know that even though rubber dam has a lot of advantages it remains as a topic of controversy. It was disappointing to note that few students reported that rubber dam is not a useful adjunct in preventing contamination. As rubber dam is an excellent tool for isolation, the reason for such response may be due to incorrect rubber dam application. The majority of students find the selection of clamp and its adaptation difficult. The reason behind it may be presence of inadequate tooth structure posing difficulty in placement of regular clamp or they were not having clamps for different teeth. Adequate knowledge about availability of various clamps in the market and selection of clamp according to the available tooth structure may help to resolve this problem. Pertaining to difficulty in placement and selection of clamp, repeated application may help to resolve this problem. Other problemsnoticed in rubber dam acceptance were patient refusal. Adequate patient education and motivation could help in overcoming this problem. Many students were not using rubber dam in pediatric patients, the reason being patients are uncooperative to this device. As rubber dam improves the quality of dental materials, proper education should be given to the parents for its

acceptance. It is rather highly disappointing to know that half of the student population think that they are obliged to use it and few opinionated that they will not be using this device further in their practice. It is accepted that there is a strong learning curve in rubber dam application and its usage, the advantage of using should be overweighed in comparison to difficulties encountered in its usage.

In a study from Belgium, about 64.5% of practitioners do not use rubber dam in their daily practice, while only a very few that is 3.4% believed that rubber dam to be a standard procedure[14]. Whitworth et al.stated that thepatients dislike towards rubber dam can be strongly determined by the cliniciansattitude. Stewardsonand McHugh et al. also stated that the experience of the dentist and the efficiency and technique regarding the usage of rubber dam in the patients oral cavityshould be achieved by frequent practice. In most of the studies practitioners are not been asked of latex allergy to the patient prior the application of rubber dam which suggests that more attention should to be directed towards the possibility of latex allergy prior to application of the rubber dam as it causes intra oral complications .

Mala et.al,stated that theincrease percentage of students who did not use rubber dam for child patients (89.1%) [15]. This difficulty however needs to be considered from a pedodontic point of view, probably in a future study focusing on this group of patients. Percentages of students with this difficult facing the rubber dam were increased than that of those who reported by Mala et al. Marshall and Page (1990) in their study used Patient discomfort as main reason for not using rubberdam[16]. But the limitation of spending extra time in placing the dam is compensated with better working conditions offered by the dam including controlling the saliva contamination and eliminating the need to frequently change cotton rolls as well as limiting the movements of the patient’s tongue and lips. As it is already evident that rubber dam may reduce the incidence of post-treatment disease during root canal treatment[17].Saranyapackiriet al reported that 37.4% believe it is a useful tool and45.8% students felt that patient’s do not like it, there by implyingin its disincentive use in future dental practice (26.2%)[18].In other study on non caries cervical lesions, Haripriya et al stated that, it is evident that majority of the practitioners are not aware of isolation methods for restoring NCCLs and those who are aware also do not imply them in their clinical practice. Therefore, knowledge about conventional methods of isolation and newer methods of gingival retraction should be imparted[19].

Conclusion

As rubber dam is considered as a standard tool in terms of proper oral health delivery care, it judicious use cannot be neglected by the students. By increasing the awareness among the patients and by heightening educational awareness among studentsthe ultimate goal of standard method of isolation can be achieved and practiced widely.

A Survey on the Preference of Spectacles or Lens in Myopic Patients

LeyaMeriam Mathews [1], M.P.Brundha [2], Shantha Sundari [3]

Graduate Student [1],Senior Lecturer [2],Department of General Pathology

Professor and Head [3],Department of Orthodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction: Nearsightedness, or myopia, is the most common refractive error of the eye, and it has become more prevalent in recent years. Myopia occurs when the eyeball is too long, relative to the focusing power of the cornea and lens of the eye. This causes light rays to focus at a point in front of retina, rather than directly on its surface. Symptoms include squinting, eye strain, distant vision not clear, and headaches .Treatment options include use of prescription glasses, contact lens, and corneal refractive therapy.

Materials and Method: To survey the myopic population using spectacles and contact lens, on certain practical issues. A comparative analysis of the use of spectacles and contact lens in terms of frequency, regularity, comfort and complications if any

Results: Most of the participants wore prescription glasses over contact lens for obvious reasons of comfort and better vision. However, contact lens was aesthetically preferred over prescription glasses and also helped give a clear vision, due to less chances of fogging.

Conclusion: The survey, meant to appraise personal opinions of myopic patients, on their use of visual aids, willhelp to understand various aspects of a very commonly used device in day to day life, the spectacle and contact lens. The study will reveal the efficacy and short comings posed by both, in the attempt to correct the inevitable.

Keywords: *Myopia, short -sight, contact lens, spectacles,aesthetics*

Introduction

Myopia also known as near-sightedness or short sight is one of the common refractive error of the eye and ocular disease in Asia.It is the state of refraction where the parallel rays of light are brought to focus in front of retina [1]. Therefore, a distant object tends to be out of focus. The onset of myopia is observed between the age of 5 and 15 years [2].Myopia is normally signified by a blurry distant vision and at times, people with high myopia, the near sight is also affected. On examination, it is often observed that, the optic nerve is tilted with pigmentation on the macula. Squinting, headaches are other symptoms observed. It occurs when the eyeball is too long, relative to the focusing power of the cornea and lens of the eye. This causes the light rays to focus at a point in front of the retina.Severe cases of myopia can even lead to blindness because of its associated ocular co morbidities of retinal detachment, macular degeneration and glaucoma [3].The cause of myopia is still debated as being pathological, congenital or acquired. However, other factors which could cause myopia are high sugar levels in diabetic patients, visual stress and even a family history of myopia could put an individual at high risk.People with myopia have several options to correct their vision. Spectacles, contact lens, laser surgery,vision therapy for people with stress related myopia and corneal refracted therapy.For most people with myopia, spectacles are primary choice for correcting distantvision. Generally, a single vision lens is required to provide a much clearer and better vision. However, certain studies show that children now opt for contact lenses as choice of treatment. Contact lenses like spectacles, provide correction of vision, but cannot be worn full time.The objective of this analysis was to find the amount of time and level of comfort felt, when the subjects wore their mode of correction and, to assess the efficacy and short comings of each

Materials and Methods

The study was conducted among the South Indian population, in Saveetha Dental College, Tamil Nadu, India, during the month of May 2017. .The subjects were selected at random, among those who attended Saveetha Dental College, Out- patient department, with visual aids. Fifty participants who accepted to participate in the study,in the age group 15 - 30 years were included in the study.

A questionnaire was prepared and distributed. Participants were questioned based on their preference to spectacles or lens on issues like level of comfort, age, advantages, disadvantages and their knowledge on other treatment options available. Subjects were asked if the prescribed mode of correction helped to correct myopia.

The collected data was then analyzed and compared accordingly.

Results

The data collected from the participants was evaluated and the following observations were made.As shown in Table 1,more number of the participants preferred prescription glasses over contact lens to correct myopia. With increase in age, the number of people whoused glasses and lens alternatively on a daily basis also increased. It was also noted that only few participants chose contact lens as first choice of treatment to correct myopia when compared to spectacles

Table I: Age based distribution of spectacle and lens users

Age group	Only spectacles used	Only contact lens used	Both	Number who used Spectacle the most	Number who used contact lens the most
15-20 years	0	0	7	5	2
20-25 years	7	2	8	10	7
25-30years	13	3	10	20	6
TOTAL	20	5	25	35	20

A few number of theparticipants used both spectacles and contact lens to treat myopia. However,when askedabout the age they had begun to use Glasses / Contact lens, data(Table II) showed that participants, when less than 10 years of age preferred using spectacles. Contact lens was used on the rise from late teenage towards young adults beyond 18 years age.

Table II: Age of commencement of Treatment

Age Group	Spectacles	Contact Lens
6-12years	6	0
13-18years	5	6
19-24years	7	9
25-30years	7	10

Among the advantages listed, aesthetics, vision and level of comfort were questioned. Data collected showed that among lens user's aesthetics and better vision (80%) was the major advantage, while comfort andvision (60%)was the primary advantage among spectacle users. (Figure 1)

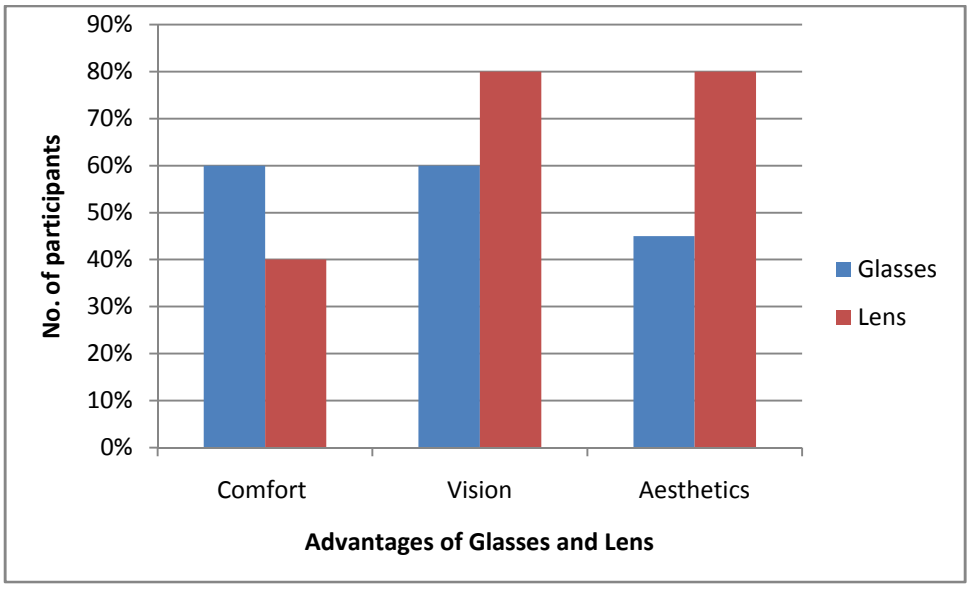

Figure 1: Comparison of advantages

However, the disadvantages listed about lens users, were also more compared to prescription glass users (Figure 2). About 80 -70% complained about irritation and the time consumption for wear, while using lens. Lens also required excessive care when compared to glasses, to avoid any damage or infection. Less aesthetics and fogging were more observed in prescription glasses. Most of the participants did not find many difficulties while using spectacles

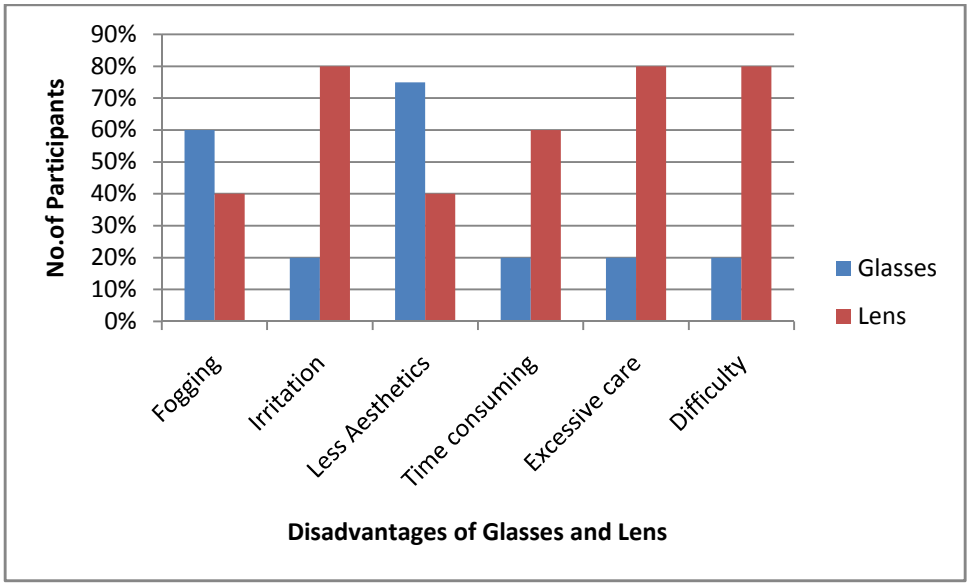

Figure2: Comparison of Disadvantages.

Knowledge about other treatment options was also asked during the survey. Laser and eye exercises were the most listed treatment options. Latest treatment options include corneal refractive treatment and Orthokeratology. (Table 3)

Table 3 Alternative ways for correction of Myopia

Age Group	Eye Exercise	Laser	Others
15-20years	5	2	0
21-26 years	7	7	3

27-30 years	10	8	8

Discussion

Myopic patients are provided with refractive correction, especially young patients, to help them have a clear distant vision .School work, sports and other activities benefit from optimal vision. Studies have also shown that myopia can further have social, economic and educational consequences, if not corrected on time [4].

The underlying pathogenesis behind myopia is still debatable whether it is acquired, pathological or congenital [5]. Studies show a possible chance that, myopia could begenetically acquired. Zadnik et.al conducted a study focusing on the refractive errors of both the parents and children. All the components of refraction of both the parents and children were measured and it was observed that children with myopic parents tend to have longer eyes than children without myopic parents. In myopia, the image is formed in front of the retina because the cornea or lens curvature is too strong or the eye is too long Hence, this factor could be a possible predisposition to become myopic later in life [6, 7]. Myopia has also been related to various ocular co morbidities like pathologies in retina, pigmentary degeneration, optic nerve crescent, bilateral rhegmatogenous retinal detachment [8].

In this study, most of the participantswore prescription glasses over contact lens for obvious reasons of comfort and better vision. It was also observed, that those participants who usedlens for a much shorter time in a day attributed it due to the excessive care needed to maintain duringwear and time consumption needed for wearing. However,contact lens was aesthetically preferred over prescription glasses and also helped give a clear vision,due to less chances of fogging.

The studies related to self-perception and physical appearance was quite interesting. It appearedthat, among thosewho used both spectacles and contact lens, those who were conscious of their looks, preferred to use lens for longer hours, in spite of being knowledgeable, that spectacles helped to retard myopic progression better. In fact, certain studies indicate that

physical appearance or self – esteem was significantly improved among those who felt good about their contact lenses [9].

Age is another factor which comes to light while judging between contact lens and spectacles. Studies show that optometrists recommend spectacles at a primary age than contact lens. Most importantly, the maturity of the child and other criteria like motivation to take care of it, personal hygiene also determined why at a primary age, spectacles is more preferred [10].

People with low myopia, tend to lose spectacles as they do not wear it whole time. Fogging of the glasses and less aesthetic appearance are other disadvantages listed out while wearing spectacles. They also do not help much in myopic correction.

From this study, it has been observed that the better choice of the treatment to control myopia is spectacles. Spectacles can be given at a primary age to children, at the age of 11, as a source of primary myopic correction. Spectacles also do not offer complete vision correction when compared to lens, but definitely more comfortableand easy to maintain. Studies show that though, spectacles were less aesthetic, they providedcorrection over a range of refractory errors, reduce retinal defocus thereby providing a corrective refractive treatment [11, 12].

Reasons cited for preferring contact lens for correction of myopia, have been better vision, ocular health, less discomfort and also boost up the self - esteem.But studies show that contact lens are not effective in retarding myopic progression[13] .Corneal curvature flattening, which could also be responsible for a myopic progression have been noted while using contact lens [14,15]. Change in axial length rather than refractive error is typically used as the outcome measure because of corneal flattening produced by the lenses. Pilot studies have shown that the use of contact lenses have also increased the progression of myopia .The longitudinal Orthokeratology research in children was a pilot study conducted in Hong Kong which showed that lenses slowed axial elongation and the progression of myopia. [16,17]. In conditions like astigmatism , which causes blurred vision due to irregular curvature of the cornea, spherical lenses was not very effective in providing a better treatment [18].

As per recent studies, it was observed that on anaverage, a person wore spectacles for 13.5 hours and lens for 11 hours but, neither contact lens nor spectacles provided total correction of vision

with time. Currently, the only mode of total correction is corneal refractive therapy, without the use of corrective device [19].

The search for an effective intervention to slow down the progression of myopia continues to be hampered due to a lack of clear understanding of the pathogenesis of myopia .Effective therapy should be more focused on environmental factors, early age of onset, retinal degenerative factors in the future. Other treatment options like orthokeratology, corneal refractive therapy, atropine drops have also been tried and better results have been yielded to correct myopia [20, 21].

Conclusion

As per the data analysis, it was observed that spectacles were more preferred over contact lens among patients who attended the out-patient department at Saveetha Dental College. At a primary age, prescription glasses were recommended by ophthalmologists, with thematurity of the child in mind, the less amount of care needed for maintenance and personal hygiene. Contact lens, although aesthetically favorable, was preferred less due to the demand for excessive care, irritation and discomfort .Studies show that both prescription glasses and contact lens did not aid in providing a complete effective treatment and other treatment options like corneal refractive treatment, Orthokeratology should be further explored.

An Endodontic Practice Profile Amongst General Practitioners In Chennai- A Questionairre Survey

Nandhini.S[1], D.Delphine Priscilla[2], V.Jayanth kumar[3]
Graduate Student[1],Senior Lecturer[2], Department of Conservative Dentistry,Reader[3], Department of Oral Medicine and Radiology,

Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences,Saveetha University, Chennai, India

Abstract

Introduction: The practice of dentistry shows a vast difference owing to the place of practice that is., between private practice and institutional one as well as between the general practitioner and the specialists. Endodontic treatment itself offers a wide gamut of options to a clinician in the way a simple root canal can be carried out. Use of rubber dam, irrigants, prescription of antibiotics, choice in Single and multiple-visit treatment and interappointment dressings are the aspects of one most commonly carried out procedure that is., root canal treatment in dentistry

Materials and Method: This study was a questionnaire-based survey of samples of dentists in Chennai. The self-administered questionnaire contained 15 close-ended questions with multiple choice options. The data collected included demographic details of respondents, root canal preparation techniques, irrigants and intra canal medicaments used, the number of appointments, method of working length determination, root filling techniques, cements used, and the scope of treatment performed.

Result: The usage of rubber dam is very low among the general practitioners. Most of the dentists follow radiograph with instrument in the canal as the best option for working length determination. Out of three root canal instrumentation techniques like crown down, push and pull and step back, the third one(56%) is the mostly followed technique. Hero shaper(51%) is the choice of Ni-Ti rotary instrument used by the dentists of Chennai followed by M Two. Stainless steel hand files(69%) are mostly used to prepare canals followed by nickel titanium hand files(21%) and rotary nickel titanium files(10%).Lateral compaction(91%) is the

commonly used obturation technique.Autoclave sterilization(20%) is mostly followed by the dentists followed by glass bead and chemical sterilization(12%).The most commonly used sealer is ZOE sealer (72%).

Conclusion: During past decade many innovative concepts, techniques and instruments have been introduced in practice. And standard of care for endodontics can be improved by increasing general dental practitioner interest. This study concludes that standard guidelines and new technologies are to be implemented by the practitioners in Chennai.

Key Words: *Endodontic practice, general practitioners, root canal, medicaments, apex locator.*

Introduction

The practice of dentistry shows a vast difference owing to the place of practice that is., between private practice and institutional one as well as between the general practitioner and the specialists. Endodontic treatment itself offers a wide gamut of options to a clinician in the way a simple root canal can be carried out. Use of rubber dam, irrigants, prescription of antibiotics, choice in Single and multiple-visit treatment and interappointment dressings are the aspects of one most commonly carried out procedure that is., root canal treatment in dentistry.With the introduction of new materials, devices and techniques, quality of endodontic treatment has increased leading to higher endodontic success rate.[1,2] With the development of these technologies, many teeth with guarded prognosis that used to be extracted in the past can be salvaged by surgical or non-surgical endodontic treatment. Endodontic treatment includes all clinical procedures designed to maintain the teeth in a functional state in the dental arch. The challenges of preserving the dental arch free of pulp and periapical diseases have contributed to numerous innovations in contemporary endodontic practice. Research data on attitude of general dental practitioners towards endodontic therapy is rare.[3] Several studies have investigated the attitudes of general dental practitioners towards various aspects of endodontic treatment in England,UK, Belgium, Nigeria, Sudan, Australia, Denmark, USA, Sweden, Turkey, Jordan and Iran. But there has been no survey of the current status of endodontic practice in India. So, the primary purpose of this survey was to determine the attitude of general dental practitioners towards endodontic

treatment and current use of new endodontic technology and materials by them.[4,5] Changes in the field of endodontics have been so rapid in recent years that current instruction in root canal treatment (RCT) bears little resemblance to that of 10 years ago. The consequence is that dentists are faced with numerous materials and techniques, while dental schools try to tailor their curriculum accordingly.In order to ensure acceptable treatment outcomes, quality guidelines for endodontic practice have been published.The aim of the study is to investigate and compare the status of endodontic practice among Indian endodontists that will help suggest a standardized treatment guideline.

Materials and Methods

The target population of this investigation was the general dental practitioners in Chennai.A sample of 100 questionnaires with 15 closed ended questions weredistributed to them in their working place.Convenience sampling was used and samples were chosen to be 100 arbitrarily.Question categories included different aspects of endodontic treatment, including root canal therapy stages, materials, choice of instruments, isolation methods, use of canal irrigants, use of intracanal medicaments and choice of obturation technique.Percentages were then calculated, based on the number of respondents to each question.The data was analyzed using descriptive statistics.[6,7,8]

Table 1: Questionnaire

1.Gender
A) male b)female
2 .Do you use rubber dam in your endodontic treatment ?
a)always
b) occasionally
c) never
3.If its more than one visit ,what intra canal medicament do you give ?

a) CaOH

b)Formocresol

c) iodoform

4.Method of working length determination

A) apex locator

B) pre operative radiograph

C)Radiograph with instrument in the canal

5.Method of root canal instrumentation

A) crown down

B) step back

C) push and pull

6.Which one do you prefer the most ?

a) step back

b) crown down

7.Which is your choice of Ni Ti rotary instrument ?

a)Profile

b) hero 642

c) pro taper

8.Length of time of use of rotary NI TI ?

A) 0 to 12 months

B) 13 to 24 months

C)35 months

D) more than 36 months

9.How do you retrieve fractured instrument?

A) ultra sonic

B) by pass the instrument

C) apical surgery

10.Which irrigating solution you use?

A) sodium hypochlorite

B) Normal Saline

C) hydrogen peroxide

11.which type of obturation technique you commonly use?

A) lateral compaction B) warm compaction c) single cone

12.Type of RCT complication which u think is more common

A) irrigant related b) perforation c) over instrumentation.

13.How do you sterilise your endodontic files ?

A) glass bead sterilisation

B) autoclave

C) chemical sterilisation

14.How do you manage emergency ?

A) analgesics and antibiotics

B) pulpectomy

C)pulpectomy and medication

15.The sealer that you use mostly is

A) ZOE

B) endomethasone

C)sealapex

Results

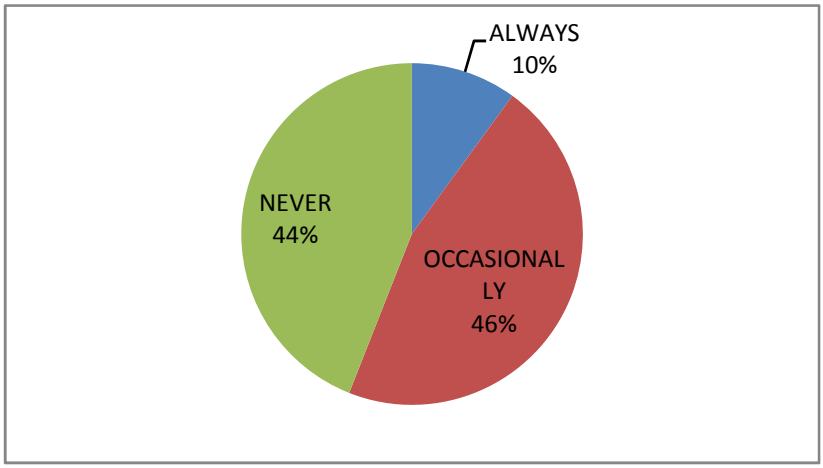

Figure 1: Frequency of rubber dam usagein clinical practice

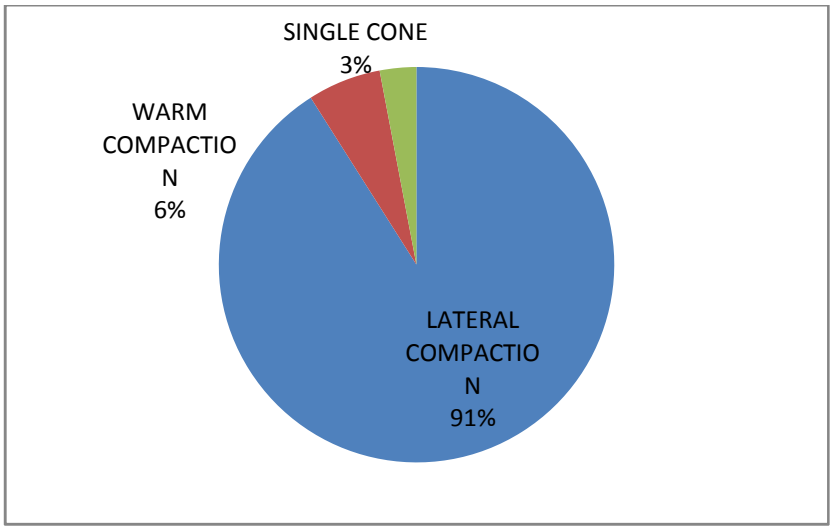

Figure 2:Type of obturating technique used

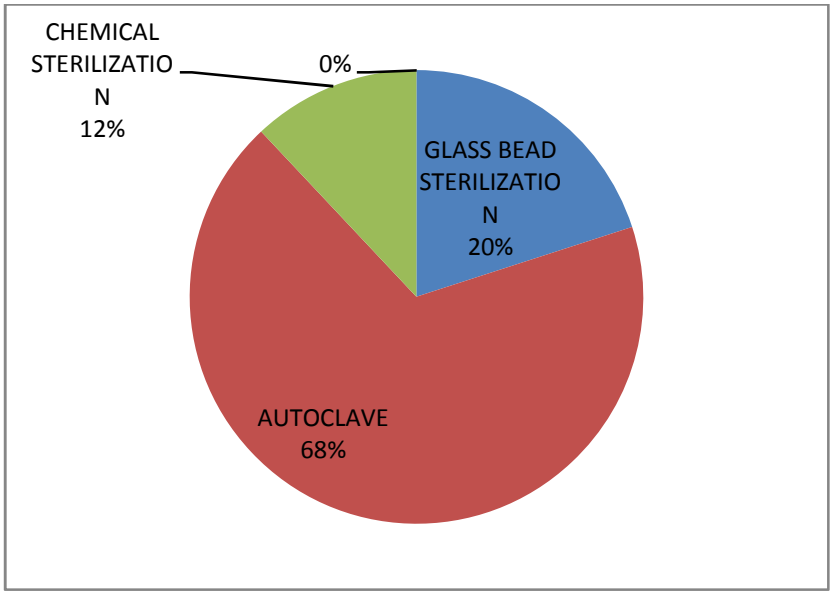

Figure 3:Sterilization of endodontic files

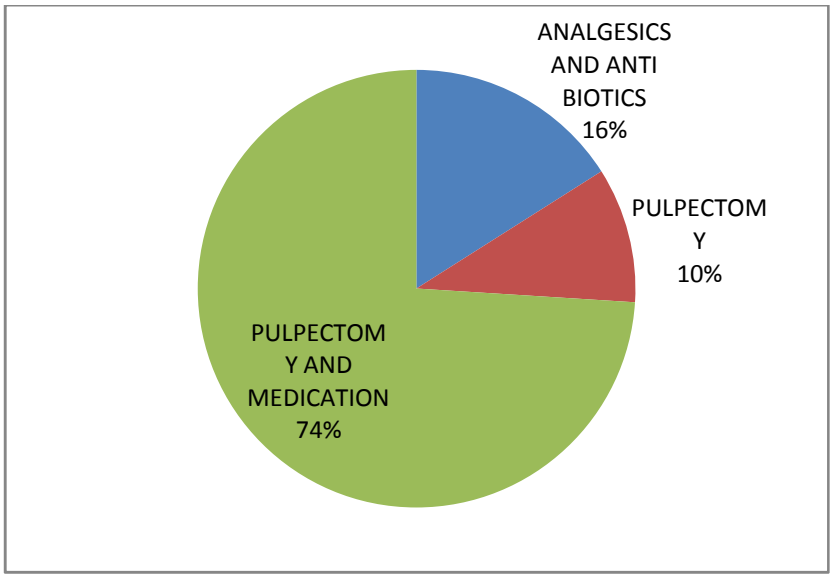

Figure 4: Mode management of endodontic emergency

This study investigated the endodontic practice profile.Out of 100 dentists here,only very few use rubber dam.The mostly used intracanal medicament is CaOH (74%) followed by formocresol and iodoform.Most of the dentists follow radiograph with instrument in the canal as the best option for working length determination. Out of three root canal instrumentation techniques like crown down,push and pull and step back, the third one(56%) is the mostly followed technique.Hero shaper(51%) is the choice of Ni-Ti rotary instrument used by the dentists of Chennai followed by M Two.Stainless steel hand files(69%) are mostly used to prepare canals followed by nickel titanium hand files(21%) and rotary nickel titanium files(10%).Most of the dentists bypass the fractured instrument(46%).Ultrasonic method(17%) and apical surgery(22%) are followed by very few dentists.Lateral compaction(91%) is the commonly used obturation technique then comes warm compaction(6%) and single cone(3%).Obturating beyond apex (42%) is the common root canal complication.Autoclave sterilization(20%) is mostly followed by the dentists followed by glass bead and chemical sterilization(12%).The most commonly used sealer is ZOE sealer (72%).Resin based(10%), calcium hydroxide based (9%) and bioceramic sealers(9%) are also used.

Discussion

A dentists' attitude, knowledge and practice can be determined in an effective manner by conducting a questionnaire survey. Face to face surveys have response rates higher than electronic or mailed questionnaires. The respondents in the current study were dentists who were able to provide valid and valuable information on the current status of endodontic practice. The major limitations and weaknesses of this study include the inflexible nature of the study design. As opposed to direct observations, it is difficult to deal with specific contexts in the current questionnaire-based study. Moreover, some questions that may be more appropriate to respondents may have been missed in an attempt to standardize the questions.[9,10,11]

This study investigated the endodontic practice profile.Out of 100 dentists here,only very few use rubber dam.Because its time consuming and patient discomfort rate is very high. All endodontic procedures should be performed with a rubber dam, which should be considered standard care. The purpose of rubber dam protection in dentistry on whole cannot be overempasized. Although rubber dam isolation is taught as mandatory during training, its importance appears to be ignored by most of the Endodontists in India.The mostly used intracanal medicament is CaOH (74%) followed by formocresol and iodoform. For intracanal medicament, calcium hydroxide usage was the most popular followed by formocresol, which was similar to that practiced by dentists in HK and endodontists of India. Calcium hydroxide has been determined as suitable for use as an intracanal medicament as it is stable for long periods, harmless to the body, and bactericidal in a limited area. It also induces hard tissue formation and is effective for stopping inflammatory exudates. Besides, intracanal dressing is also for a blockade against coronal leakage from the gap between filling materials and cavity wall. On the other hand, formocresol has a tissue fixative property and also is distributed to the whole body from the root apex and so might induce various harmful effects including allergies. Furthermore, as these medicaments are potent carcinogenic agents, there is no indication for these chemicals in modern endodontic.Most of the dentists follow radiograph with instrument in the canal as the best option for working length determination.With use of either electronic apex locator or radiographs, the respondents preferred to be short of the apex, while Lee et al. in their survey showed that 30-40% of respondents instrumented to the level of apex reading on the electronic apex locator regardless of the clinical situation[12,13,14].

Periapical radiographs are important in endodontics for diagnosis, determine the number, location, shape, size, and direction of roots and root canals, estimate and confirm the length of root canals before instrumentation, localize hard-to-find, or disclose unsuspected, pulp canals by examining the position of an instrument within the root, aid in locating a pulp that is markedly calcified and/or receded, determine the relative position of structures in the facial–lingual dimension, confirm the position and adaptation of the primary filling point and aid in the evaluation of the final root canal filling.This method can be useful in patients who need not to be exposed to repeated radiation because of mental, medical or oral conditions.Moreover, electronic apex locators areparticularly useful when the apical portion of the canalis obscured by anatomic structures, such as impactedteeth, tori, the zygomatic arch, excessive bone density,overlapping roots or shallow palatal vaults. Irrigation has been performed in conjunction with endodontic therapy for many years. One of the primary reasons for irrigating the root canal system is to ensure cleanliness of the canals prior to obturation. This cleanliness involves both elimination of microorganisms and removal of organic matter.Out of three root canal instrumentation techniques like crown down,push and pull and step back, the third one(56%) is the mostly followed technique. A crown-down approach provides certain advantages including early organic debris removal, the creation of a large reservoir for irrigating solutions, a straighter access to the apical region of curved canals, and greater precision with regard to the exact working length and apical size.20 Only 23 % of the GDPs used crown-down technique while 90% still followed step-back technique.Hero shaper(51%) is the choice of Ni-Ti rotary instrument used by the dentists of Chennai followed by M Two.Stainless steel hand files(69%) are mostly used to prepare canals followed by nickel titanium hand files(21%) and rotary nickel titanium files(10%). Non-rotary manual endodontic files were commonly used by the endodontists surveyed. Recently introduced rotary NiTi files are able to produce a uniformly tapered canal configuration without canal transportation.[13,14,15]

However, unpredictable instrument separation remains a deterrent to their popularity. Moreover, cost of rotary files also restrained their use in the developing countries like India. Majority of respondents only replaced their instruments when signs of distortion and bluntness were obvious, which is likely to result in a higher risk of instrument separation in the canal. Most of the dentists bypass the fractured instrument(46%).Ultrasonic method(17%) and apical surgery(22%) are followed by very few dentists.Lateral compaction(91%) is the

commonly used obturation technique then comes warm compaction(6%) and single cone(3%).The preferred technique for filling the root canals in the current study was the lateral condensation technique and this has been reported as the most universally accepted technique.5 It is also the preferred technique among undergraduate dental students.[16,17,18]Obturating beyond apex (42%) is the common root canal complication.Autoclave sterilization(20%) is mostly followed by the dentists followed by glass bead and chemical sterilization(12%).The most commonly used sealer is ZOE sealer (72%).Resin based(10%), calcium hydroxide based (9%) and bioceramic sealers(9%) are also used.

There are some limitations of the present study which are worth mentioning. Since, the study used a face to face questionnaire it was not possible to survey a large sample size. The survey didn't attempt to differentiate the participants based on their specialty and training. Hence, it could be assumed that not all the dentists would perform all procedures listed in the questionnaire frequently. This could result in their response to be based on knowledge and not on routine practice.

Conclusion

This study investigated and compared the status of endodontic practice among Indian endodontists. It showed that dentists are following the basic protocols and techniques in accordance with recognized international standards. But still there are certain differences that suggest a need for standardization of treatment guidelines for the Indian specialist.[19,20] These findings would help reach a consensus to set an Indian endodontic treatment protocol/guideline by the Indian Board of Endodontists similar to one done by European Society of Endodontists, American Association of Endodontists and the Canadian Academy of Endodontists.Duringpast decade many innovative concepts,techniques and instruments have been introduced in practice.And standard of care for endodontics can be improved by increasing general dental practicionerinterest.This study concludes that standard guidelines and new technologies are to be implemented by the practicioners in chennai.[21]

Abstract

Introduction : Many students have malocclusion in our population but the accurate percentage of students with malocclusion has not been determined properly. Hence dentists are not aware of how much percentage of people requires treatment. This study is to estimate the various reasons that why school children with malocclusion have not started orthodontic treatment, particularly in Chennai population and also how many people requires orthodontic treatment.

Aim and Objectives: The survey is to analyse the reason why school student are not talking orthodontic treatment between 15-20 years of age particularly in Chennai.

Materials and Methods: 517 school students from Chennai region who are between ages of 15-20 who have not undergone any orthodontic treatment or extraction will be examined intraoral to detect the malocclusion. The examination for malocclusion was made according to DAI as described in WHO Oral Health Survey Basic Methods, 1997. Data collected were statistically analyzed.

Result: The analyzed data shows about 68% of students in the sample are aware about their irregular dentition and 32% were not aware of their malocclusion since they don't have any functional problems. Only 10% of students were aware about various orthodontic treatments and remaining 90% of people are not aware of any orthodontic treatments that would help them to correct their malocclusion in both functionally and esthetically.

Conclusion: This study reveals lack of awareness in school children about orthodontic treatment. Hence a proper awareness and treatment protocol should be given to children and their parents. This enables them to think in better way for opting orthodontic treatment in future.

Key Words: Malocclusion, Orthodontic treatment, Dental aesthetic index, Aesthetics, Awareness.

Introduction

Malocclusion was defined as a deviation of teeth or a malrelationship of the dental arches over the level of what is accepted as normal.[1] even though malocclusion is not life-threatening,[2] it may be regarded as a public health problem because of its high prevalence and preventive treatment availability.[3] Malocclusions occupies the third highest prevalence with in oral diseases, second only to the tooth decay and periodontal disease, hence ranked third among world-wide dental public health precedence.[4]

Malocclusion occurs as a result of orofacial deformities and various etiological factors,[4] which result in various complications such as psychosocial problems related to impaired dentofacial aesthetics, disruptions of oral function, such as mastication, swallowing and speech and greater susceptibility to trauma and periodontal disease.[1] Several studies have emphasised on its impact on quality-of-life.[5,6] Since the public equates good dental appearance with success in many pursuits and societal forces define the norms for acceptable, normal and attractive physical appearance, persons with malocclusion may develop a feeling of inferiority bout their dental appearance and may feel shame in social situations this even leads to loss of their career promotion. Several methods are available which can be used to evaluate, describe and classify occlusion. Malocclusions are evaluated by dental aesthetic index (DAI), since its development in 1986; the dental aesthetic index (DAI) has proven to be simple and rapidly applied. [7] Some existing reports have demonstrated the high accuracy and validity of this index, which also compares favourably with other indices. [8, 9] It gives a mathematical value that links clinical and esthetic components to produce a single score hence it is called as a cross cultural index. This index can be used for various communities and populations without any necessary for modification. [10] According to World Health Organization (WHO), these main oral diseases should be described to periodic epidemiological surveys. The epidemiological information's on orthodontic treatment need was the interest of dental public health programs, clinical treatment, screening for treatment precedence, resource planning and third party funding.[4] estimating the value of distribution of malocclusion in childhood can make steps to prevent such a disorder and its complications and make it possible to decreasing the complexity of costly orthodontic treatment. Later, this information might help to minimize or eliminate future treatment need.

Malocclusion is one of the main reasons why a person would like to take orthodontic treatment. It's also related to the esthetic concern.Smile is an attractive thing in human appearance, a well-balanced smile is one of the important treatment goals of modern

orthodontic therapy, extensive studies on facial features have resulted in the establishment of norms that orthodontists use as guidelines to evaluate facial forms to direct therapy [11]. But many time we surprised to see that so many people in a general population with unaesthetic smile and severely misalignedteeth who have still not opted for taking up orthodontic treatment. If esthetic is the only reason for taking up orthodontic treatment, most of these people would have taken up orthodontic treatment. So this leads to the question, is that any other reason why patients who obviously have malocclusion and smile which is unaesthetic are not willing to take up orthodontic treatment. This study aims at finding out the reasons for not taking up orthodontic treatment which will help the orthodontist in future to realize the problems faced by patients and find solutions for the same.

Materials and Method

Information was collected by a single examiner. The examiner visited the school on particular dates according to schedule. The examination for malocclusion was made according to DAI as described in WHO Oral Health Survey Basic Methods, 1997.[12] Survey was conducted among the school students of velammal matriculation higher secondary school, ponneri - Chennai. Eligible children were identified and given informed consent forms to get them signed from their parents/guardians who were also notified by the school teachers on request of the investigator. A total of 517 female students of age group between 14-18 years were included in the study. A pre-structured questionnaire consisting of few questions with multiple options were given to the children to elucidate about their misaligned dentition and reason why they are not taking up orthodontic treatment.

Initially Dental Aesthetic Index (DAI) was developed in the United States of America and incorporated into the International Collaboration Study of Oral Health Outcomes by the World Health Organization (WHO, 1989) as an international index, identifies occlusal traits and mathematically derives a single score. [13] It plays an important advantage in public health programmes, paves a platform for the dentist to explain the quality of life given by the orthodontic treatment.

The DAI was based on socially defined aesthetic standards. It conjoint the gap between the aesthetic and clinical aspects of occlusion by mathematically produces single score. It has some limitations such as it couldn’t identify cases with deep overbite that impinge on gingival or palatal tissue. The DAI was developed as a screening tool for permanent dentitions; it may be not applicable for mixed dentition stage accompanied with changes in future dental appearance. [14] The DAI was evidentially proved to be reliable, simple, valid,

and user-friendly. [15, 16] Hence, it can be used and adapted globally and cross- culturally without any modification. [17, 18]

The following questionnaire format is to analyze the reason why people are not taking up orthodontic treatment,

- Name Age Sex Mobile No.
- Are you aware of your irregular teeth?
- Have you visited a dentist regarding your teeth alignment?
- Are you aware of the various treatments options that are available to correct your teeth alignment? ☐ Yes ☐ No
- Why have you not started treatment for teeth alignment?
- _____
  _____
  _____
  _____
  _____
  _____
  _____
  _____ Your Signature

Result

Questions	**Yes Percentage**	**No Percentage**
Awareness of irregular teeth	68%	32%
Visited to a dentist regarding teeth alignment	45%	55%
Awareness of various orthodontic treatment option	10%	90%

The analyzed data shows about 68% of students in the sample are aware about their irregular dentition and 32% were not aware of their malocclusion since they don't have any functional problems. Only 10% of students were aware about various orthodontic treatments and remaining 90% of people are not aware of any orthodontic treatments that would help them to correct their malocclusion in both functionally and esthetically.

Reasons

S.No:	REASON	PERCENTAGE
1	Fear of post operative pain	6
2	Fear of extraction	13
3	Crowding of back tooth region, have aesthetic smile	2
4	Fear of teeth mobility	7
5	Lack of time	10
6	Scared that my facial structure might change	3
7	Because of 12^{th} board exams	10
8	Not aware of misaligned teeth	12
9	Dentist suggests that start treatment after 18yrs of age	1
10	Facial appearance with braces will be bad	8
11	Parents are not willing for treatment	2

12	Fear of pain and inability to take food	5
13	Crowding is not affecting my aesthetic	10
14	Expensive	5
15	Uncomfortable to wear braces	6

Pre-structured questionnaire were given to 517 students of velammal matriculation higher secondary school, ponneri. The data collected from those questionnaires were analyses and the following results were concluded. About 6% of students have fear of post operative pains, 13% percentage of students have fear of extraction, 2% has crowding of posterior teeth hence they have good esthetics and are not willing for orthodontic treatment, 7% of students have fear of post operative tooth mobility, 10% of student says lack of time for treatment,3% of student reason out that their facial structure would change, 12% of students are not aware of their misaligned teeth,10 % of student says that they would start treatment after their schooling, 8% of students feel that they would have bad appearance with braces, 2% of students parents are not willing for treatment, 5% of student feels that they can't take proper food during treatment duration, 10% of student says that crowding
Is not affecting their aesthetics, 5% of students feel that orthodontic treatment is expensive, and 6% of students feel uncomfortable to wear braces.

Discussion

The inheritance of malocclusion is developed by genetic and environmental factors, but with a greater significant on the effect of oral environment in particularly the orofacial tissues such as positioning of tongue.[19-21] study shows large tongue with increased length of lingual frenum are always associated with class three malocclusion, while class I and II shows less significant variation in length of lingual frenum.[22]This study shows that about more than 60% of children were aware of their own teeth mal-alignment. Remaining 40% of student has malocclusion but they don’t notice before and so they are not aware of their misaligned teeth. Only those who were aware of malocclusion were included in this study. Students who were undergone orthodontic treatment, cleft lip and cleft palate were excluded in the survey. Students who are aware of malocclusion are not taking orthodontic treatment for Several reasons such as post operative complication, fear of extraction, malocclusion of posterior tooth , postoperative mobility, changes in facial structure, lack of time due to board exams, dentist suggested to start treatment after 18 years of age, unaesthetic appearance during

treatment period, parents are not aware and no willing for their kids orthodontic treatment, inability to take proper foods, misaligned to is looking good and it's not affecting my esthetics, expensive and discomfortable in speech while wearing orthodontic brackets.

People always enquiries about treatment options, before they go for the treatment or giving a try for those options. Likewise before planning for orthodontic treatment they would have heard some myth statements about orthodontic treatment. Like Postoperative mobility, improper food intakes are some reasons would have made scary for the children and their parents; some children are scared of extraction that is because of poor dental experience in childhood due to anxiety. Hence a proper awareness and treatment protocol should be given to children and their parents. This enables them to think in better way for opting orthodontic treatment in future.

Conclusion

This study reveals lack of awareness in school children about orthodontic treatment.

Most children with malocclusion have not started their treatment due to ignorance of treatment protocols, extraction, periodontal problems, lack of knowledge about malocclusion and other influencing factors like literacy rate and socio-economic status. Malocclusion has an impact on the social and the psychological behavior of an individual; hence knowledge on how individuals perceive and react to malocclusion in a community is necessary for effective orthodontic treatment and care.

Analysis of Knowledge about the Hospital Warning Symbols among the Clinical Dental Assistants in a Private Dental College in Chennai – A Comparative Study

Sharanya.H [1], Brundha M. P [2], D.Sri Sakthi [3]
Graduate Student [1],Senior Lecturer [2],Department of General Pathology
Reader [3],Department of Public Health Dentistry
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,
Saveetha University, Chennai, India

Abstract

Introduction: Hospital Safety Signs Are The Main Means Of Communicating Health And Safety Informations. There Are Specific Colors, Shape And Patten Of The Safety Signs. They Include The Use Of Illuminated Signs And Hand Signals . These Symbols Are Critical To Understand Without The Prime Knowledge . Health Care Workers Come Across These Signs Every Day In Their Working Environment. It Is Very Important To Make Them Aware And Train Them In Interpreting Theses Symbols Correctly.

Materials And Methods : A Questionnaire Containing 20 Frequently Encountered Hospital Signs Were Given To 40 Clinical Dental Assistants Pre And Post The Training Sessions. The Difference In Knowledge Before And After The Sessions Were Statistically Analysed. The Questionnaire Was Tested For Its Face And Content Validity.

Results : The Total Number Of Participants Were 40,With A Mean Age Of 22.2 Years. During Pre-Training, Majority Had Scored Below 10, 23(57.50%), Post Training Scores Improved Drastically And Majority Scored Between 10 – 15, 24(62.19%).

Conclusion: Based On The Aims And Objectives Of The Study, It Can Be Concluded That Knowledge Scores Of The Clinical Assisstants Improved Post Training. Majority Of Them Had Fair Knowledge Post Training. Hence Periodic Training And Calibration Can Improve Their Awareness And Attitude Towards Interpreting The Hospital Warning Symbols.

Keywords: *Hospital Warning Symbols, Dental, Private Dental*

Introduction

Hospitals Are Those Institutions Which Have Existed Since Time Immemorial In One Form Or The Other And Have Become More Complex In The Present Time Frequented By People From Every Walk Of Life Without Any Distinction Between Sex, Age, Caste And Religion . Recently, There Is A Significant Increase In The Dental And Medical Teaching Hospitals And Correspondingly There Has Been Tremendous Increase In The Amount Of Biomedical Waste Generated By The Hospitals.

Waste Generated In A Teaching Hospital Is Similar To That Generated By Other Hospitals Which Includes A Large Component Of General Waste And A Smaller Proportion Of Hazardous Waste. Dental Professionals And Clinical Assistants Who Work In The Clinic Are At A Greater Risk For Acquiring Cross-Infection While Treating Patients. This Is Evident From The Fact That Most Of The Human Pathogens Have Been Isolated From Oral Secretions. Hospitals Use Instruments And Materials That Are Directly Exposed To Blood And Saliva And Are Therefore Potential Sources Of Infection. Hence It Is Most Important To Acquire Knowledge For Clinical Assistants To Deal With These Biomedical Wastes Generated In The Hospitals [1].

A Study Of The Knowledge, Attitude, And Practice On Usage Of Personal Protective Equipment Was Carried Out And An Attempt Was Made To Create Awareness Among The Workers About Its Importance. Personal Protective Equipment Is Designed To Protect The Skin And The Mucous Membranes Of The Eyes, Nose, And Mouth Of Dental Healthcare Personnel From Exposure Toblood Or Other Potentially Infectious Material.Occupational Safety And Health Administration Mandates That These Ppe In Specified Circumstances Reduces The Risk Of Exposure To Blood Borne Pathogens.

Personal Protective Equipment (Ppe) Is Used To Create A Protective Barrier Between A Worker And Hazards In The Workplace. Ppe Includes Such Equipment As Chemical Resistant Gloves, Safety Shoes, Hard Hats, Safety Glasses, Respirators, And Clothing Such As Gowns And Aprons. Cleaners And Sweepers Play Important Roles For Keeping The Area Clean. Their Works Entail Removing Of Debris From Area Collecting Solid Waste, Disposing And Recycling Waste Material. Consequently, They Have Higher Chances To Be Exposed To Numerous Risk Factors; Therefore, Their Occupational Safety And Health Hazard Became Crucial. There Is Little Evidence About The Sweeping Practices, Perceptions And Knowledge On Their Occupational Safety And Health Hazards[2].

We All Encounter Symbols Day To Day In Life. Symbols And Pictorial Representation Convey Messages Easily And Are Retained In Pictographic Memory Than Text Explanations And They Do Not Have Any Langiage Barrier. Warning Symbols Can Be Found Anywhere, Hospitals, Factories, Health Centers, Or Other Public Places. These Symbols Come In Varied Colours And Backgrounds And Are Considered Essential For Safety At Work And Other Places.

Safety Sign Is An Information Or Instruction About Health And Safety At Work Place On A Sign Board, A Colour, An Illuminated Sign Or Acoustic Signal ,Verbal Or Hand Signal. .The Sign Board Is A Combination Of Shape ,Colour And Symbol Or Pictographs Made Visible By Adequate Lighting And Which May Have Supplementary Text. The Basic Principle For Understanding Safety Symbols Remains The Same Like Colour And Shape Of Outline Symbol But Some Of The Icons Have Changed [3].

Warning Signs Should Be Used To Make People Aware Of A Nearby Danger. For Example, A Flammable Liquid Store Or A Laboratory Where Radioactive Substances Are In Use Should Have An Appropriate Warning Sign Near The Entrance. Signs Warning Of A Particular Hazard Consist Of A Black Band In The Shape Of An Equilateral Triangle. The Background Within The Band Should Be Yellow With The Pictographic Representing The Type Of Hazard In Black Placed Centrally On The Sign [4].

Mandatory Signs Should Be Used To Indicate Actions That Must Be Carried Out In Order To Comply With Statutory Requirements. Symbols Are Indicated In White On A Blue-Coloured Circular As A Background.Mandatory Signs Specify An Instruction That Must Be Carried Out To Vehicles, Workers, Visitors To Sites And Any Other People That Might Need To Know The Instruction. These Can Be Used In Construction Sites, Building Sites ,Hospitals (Protective Eye Wear), And Mine Sites . Sign Wording Is Printed In Black To Give Clear Instructions. Often Mandatory Signs Can Be Used In Conjunction With Other Signs, Traffic Lights And Bollards As Visual Communication To Workers, Drivers, Pedestrians, Visitors And People Regarding Risks[5].

The Radiation Hazard Can Be Particularly Relevant For Young Patients And Especially Children, Whose High Biological Susceptibility And Long Life Expectancy Tend To Increase The Likelihood Of The Effects Of Not Only Cancer But Also Other Non-Cancerous Dis-Eases. In This Respect, Evidence Exists That Imaging Parameters For Paediatric Examinations Are Frequently Not Adjusted To The Smaller Sizes Of Children Compared With Adults, Resulting In An Unnecessarily High Radiation Exposure[6].

The Use Of Radiation In Medical Applications Continues To Increase Worldwide. According To The Latest The United Nations Scientific Committee On The Effects Of Atomic Radiation (Unscear) Reports About 4 Billion X-Ray Examinations Are Performed Annually In The World . Ionizing Radiations Is One Of The Most Common And Robust Diagnostic Tools For Many Diseases. Beside Their Advantages, As With Any Medical Interventions, There Are Some Potential Risks In The Application Of Ionizing Radiations .Ionizing Radiations Have Been Reported As Carcinogen[7]. The Risk Of Radiation-Induced Cancers Varies With The Type Of Radiation, Exposure Time, Exposed Tissue And Patient Age.

Therefore, It Is Necessary To Consider The Principles Of Occupational Radiation Protection For All Staffs Of Diagnostic Imaging Departments. As Low As Reasonably Achievable (Alara) And The 10-Day Rule Are Important Radiation Protection Principles Which Set To Avoid Unnecessary Radiation Exposure Of The Staff [8].

A Laboratory Is A Place Where Dangerous Events Can Occur, From High Voltage Stations To Biohazards To Corrosive Substances. Many People Are Unaware Of The Dangers Lurking In A Laboratory. To Alert About The Hazards Such As Biohazards And High Voltage Stations, There Are Hazard Signs Placed In Laboratories [9]. Day To Day We Will Commonly Find Hazard Signs In A Laboratory, Alerting Us To Various Hazards We Are Expected To Find. However, Many People May Not Be Able To Identify What These Hazard Symbols Mean. To Help People Get Aware Of The Various Meanings Associated With Each Sign, This Study Was Concentrated In Educating And Making The Clinical Assistants Who Work In Hospitals And Laboratory To Create Awareness Among Different Hospital Warning Symbols Used In Hospitals [10].

Materials and Method

Study Design Descriptive Study Design

Study Area Study Was Conducted Among Clinical Dental Assistants Of Saveetha Dental College.The College Has A Steady Patient Inflow Of Approximately 1000 Out Patients Per Day. Highly Trained Auxiliary Personnel Help In Clinical And Non Clinical Duties Of The Patient. It Is Highly Imperative That, These Auxiliary Persons Get Adequately Trained And Are Aware About The Bio Hazardous Environment They Work, Day In And Day Out.

Study Population A Total Of 40clinical Assisstants Aged Between 24-27 Years Were Included In The Study According To There Knowledge And The Perception Level The Various Hospitals Warning Symbols Were Selected. Pre-Training And Post-Training Evaluation Were Done.Clinical Assistants Who Were Not Able To Identify The Certain Symbols Were Given Effective Training In Such A Way That They Could Identify The Symbols During Post Training Evaluation.

Inclusion Criteria

All Clinical Assistants Employed Under Saveetha Dental College Are Included In The Study

Exclusion Criteria

***** Clinical Assistants Who Were Not Interested To Participate In The Study Were Excluded.

* Clinical Assistants Who Were Not Available During Scheduled Time Of Data Collection.

Ethical Clearance

Prior To The Start Of The Study,Ethical Clearance Was Obtained From The Scientific Review Board And Institution Ethics Committee Of Saveetha Dental College.

Scheduling

Data Collection Was Scheduled For A Period Of One Month From November To December 2016.

Survey Instrument

A Template Consisting Of 20 Various Hospital Warning Symbols Like Biohazard, Eye Protection,Flammable,Radiation,ProtectiveGloves,High Voltage Hot Surface,LowTemperature,Laser,Corrosive, Noise, Dangerous Chemical,Explosives,MedicalWaste,HarmfulGoods,FireAlaram,Toxic Gases, Slide Door Left ,Slide Door Right And Emergency Exit Was Designed.

Survey Proceedings

The Questionnaire Was Given Pre And Post Training To Evaluate The Difference In Knowledge Scores. The Training Sessions Were Given To The Particpants For A Period Of 3 Days, 20 Minutes Sessions Each. The Faculty Who Was Training The Clinical Assisstants Were Calibrated Before The Sessions.

Personal Training

Method Of Training Used Was Case Study Method (Off-The-Job Method).The Type Of Training Used In Our Current Study Was Induction Or Orientation Training.Induction Training Is A Systematic Training Plays An Important Role In A Part Of The Organisation Overall Planning Process And Is In Line With Its Goals.Induction Training Provided The

Clinical Assistants With A Better Knowledge And Perception And Response Rate In Indentifing The Warning Symbols Than Those Response Which Got During Per Training.Hence The Training Given Was Seemed To Be More Effective.

Statistical Analysis

Descriptive Statistics Was Done Using Frequency And Percentages And Inferential Statistics Done Using ChisquareTest To Test Whether The Difference In Pre And Post Treatment Scores Were Statistically Siginificant. Siginificance Level Was Set At 5%.

Results

All The Clinical Dental Assistants Working In Saveetha Dental College And Hospitals Participated In The Study And The Response Rate Was 100%.A Total Of 40 Female Assistants, With A Mean Age Of 22.2 Years(18.25 Years) Were Enrolled In The Study. The Pre And Post Training Scores Were Grouped As <10 (Poor), 10-15 (Fair) And 15 To 20 (Good) Respectively.

Majority Of The Pre Training Scores Belonged To The Poor Category, 23(57.5%). The Scores Improved Post Training. Majority Of Them Belonged To The Fair Category, 24(62.19%). Figure 1 Depicts The Comparison Of Knowledge Scores Pre And Post Training.

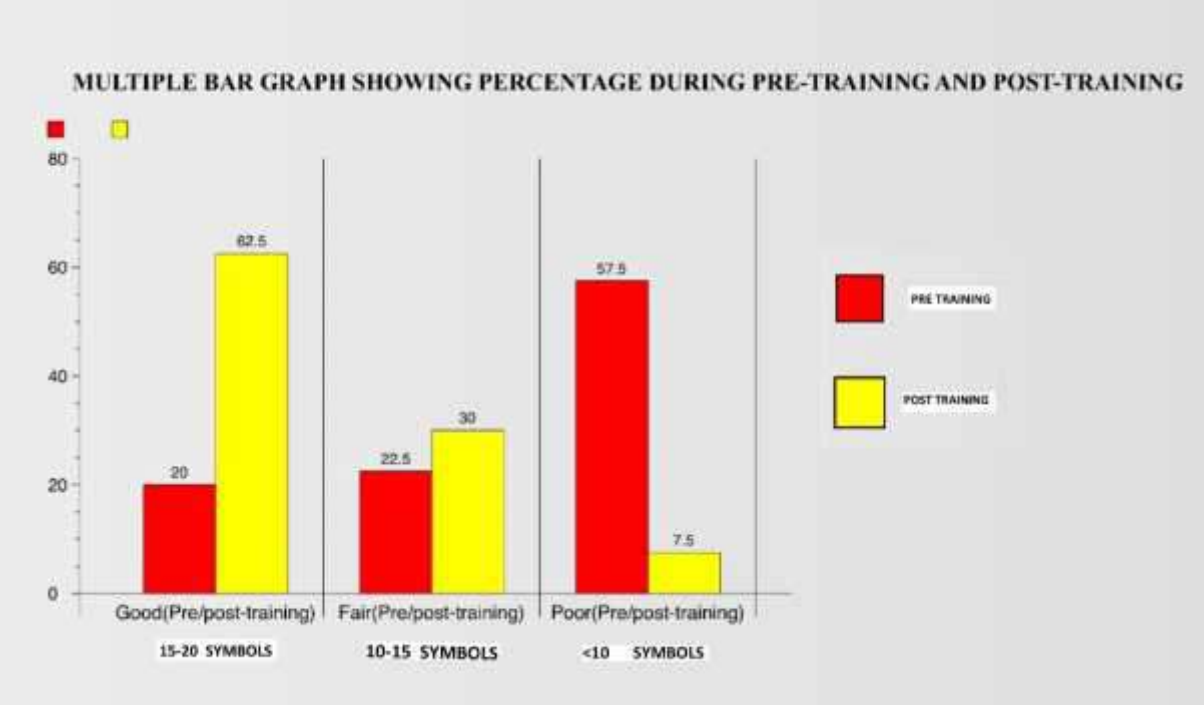

Figure 1: Pre And Post Training Knowledge Scores Comparison Among The Study Participants

Discussion

The Current Study Was Conducted On 40 Dental Clinical Assistants. The Response Rate Was 100% And There Was No Attrition In The Study. As Projected In The Results, The Knowledge Scores Drastically Improved After Training. A Large Proportion Of (62.5%) Of The Participants In This Study Demonstrated Good Knowledge Of Radiation Hazards Symbol And Mandatory Signs And Symbols Used In Hospitals. This Result Was Consistent With That Obtained In A Study Conducted In Three Hospitals In Port Harcourt,Nigeria,In Which(58.7%)Of Radiographers Were Aware Of Dangers Of Ionising Radiation And The Symbol Pertaining To It [11].

On The Contrary The Study Conducted By Iral D' Souze Et Al, The Respondent Had Average Awareness About Eye Protection (Ppe) (52.3%).This Result Was Compared To The Current Study Were The Study Participants Had Good Knowledge 82.8% Regarding Personal Protective Equipment Used In Hospitals And Laboratories [12].

According To TsegayeSewent Et Al, The Study Shows That Subjects Involved In The Study Has Poor Knowledge 32.7% Regarding Flammable Symbols And There Risk In Day To Day Life.This Result Was Compared To Our Study Were The Knowledge Level Was Increased To 73.7% [13].

The Study Conducted By Harvi Et Al., Showed That Majority Of The Participants (72.2%)Were Able To Analyse The Use And The Purpose Of Wearing Gloves (Ppe) In Hospitals,Laboratories And Health Care Centers. When This Results Were Compared To Our Current Study It Showed That Participants Enrolled In Our Study Had More Knowledge 92.5% Regarding Personal Protective Equipment Used In Hospitals [14].

According To J.A Hoops The Study Revealed That Subjects Encoded In The Study Had Poor Knowledge 42.6% Regarding Electrical Hazards Used In Hospitals And Electrical Board Centers .The Study Was Compared With J.A Hoops Et Al Showed Significant Increase In Awareness About High Voltage Symbols In Hospitals And Electricity Board Centers [16].

The Study Conducted By S.Mounika Et Al Says That Participants Involved In The Study Has Average Knowledge 50.9% Regarding The Hot Surface Warning Symbols Used In Laboratories,Hospitals And Workshops.The Results Were Compared To Our Current Study There Was No Significant Difference,Hence The Study Shows Awareness Rate About 47.2% [17].

According To T.L Fisher, Et Al., The Study Revealed That The Subjects Have Poor Knowledge Regarding The Chemical Hazard 37.5% .Hence When Is Was Compared To Our Study There Was Little Increase In The Knowledge Level Of The Participants [18].

According To Swapnill Et Al ,The Study Showed That The Workers Had Good Knowledge 78.3% Regarding Awareness Of Laser In Dentistry And Medical Field .The Results Were Compared To Our Current Study There Was No Significant Difference,Hence The Study Shows Awareness Rate About 75.3% Regarding The Laser Warning Symbols Used In Hospitals And Health Care Centers [19].

The Study Conducted By Robync,Et Al., Showed That Participants Had Poor Knowledge 37.8% Regarding Corrosive .Where Has In Our Current Study There Was Significant Increase In The Knowledge And The Awareness Level Of The Participants Enrolled,Which Was About 72.3% [20].

A Study Done On Radiation Protection By Svenson And Petersson Among Swedish Dental Practitioners Revealed Their Knowledge, Attitude, And Practices In The Field As Dentist Having Higher Level Of Knowledge which Was 84.2%Hence The Current Study Also Revealed That Subjects Have A Good Knowledge As Same As Svenson Et Al 80.5% .Hence There Was No Significant Difference Found Between Them [21].

In Another Study, Among Invasive Cardiologists Whereas Almost All The Participants (93%) Had The Good Knowledge Regarding Lead Apron, And Other Radiation Protective

Measures Including Thyroid Collar And Lead Eye Glasses; This Was Attributed To The Fact That While Lead Apron Was Available, The Other Devices Were Available To Less Than A Third Of Participants.When Results Were Compared With Our Study,The Subjects Had Average Knowledge In Radiation Protection [22].

The Overall Results Of A Study Conducted On Clinical Assistants Indicated That These Had Good Awareness And Perception Level (62.19%) About Warning Symbols Used In Hospitals As Compared To Another Study In Which Most Of The Students Were Not Having Adequate Knowledge Regarding Hospital Warning Symbols . Reports Of A Study Conducted On Dental Staff [Dentists, Dental Auxiliaries And Attenders] Revealed That Staff Had Good Attitude Towards Biohazard When Compared To The Findings Of Another Study In Which Many Dentists Had The Knowledge About Waste Management But They Lacked In Attitude And Practice . Also, There Were Poor Levels Of Knowledge And Awareness About Biohazard , Legislation And Management In Two Other Studies Conducted In Delhi And Rajasthan .

During The Pre Training ,The Most Easily Identifiable Symbols Among 20 Were Flammable, Corrosion , Eye Protection , Hand Protection And Radiation Hazards. The Non Ionising Radiation Was Mistakenly Identified As Wifi Symbol. Laser Symbol Was Mistaken For Sun, Also Low Temperature Was Mistaken For Snow Flake. But All These Changed In The Post Training Session. In This Present Study Majority Of The Pre Training Scores Belonged To The Poor Category, 23(57.5%). The Scores Improved Post Training. Majority Of Them Belonged To The Fair Category, 24(62.19%).Despite The Appreciable Results Obtained Post Training, If Theory Needs To Be Put In To Practice, Continuous Training And Calibration Of These Health Care Workers Needs To Be Done.

Conclusion

Based On The Aims And Objectives Of The Study It Can Be Concluded That Mandatory Training And Periodic Calibration Is Required For All The Health Care Workers Who Are At Potential Risk Of Getting Exposed To Bio Hazardous Materials.

Assessment about Reasons for Extraction of Primary Tooth among Dental Practitioners- A Survey

Savitha P[1], Mahesh Ramakrishnan [2], Pradeep.S [3]

Graduate Student [1],Reader [2],Department of Pedodontics

Senior Lecturer[3], Department of Conservative Dentistry and Endodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction: Extraction of primary tooth in a populations provide information about the prevalence of dental care, the availability of dental care, and attitudes towards extraction. To investigate the reasons for primary teeth extraction and the tooth type most frequently extracted in population.

Materials and Method:A questionnaire with 10 structured questions were prepared and distributed among 100 dentist practitioners to obtain information. The question were designed to determine the level of knowledge about the reasons and tooth type being extracted.

Result:the most common reason for extraction of teeth is due to dental caries among other reasons and the common type of teeth extracted due to dental caries is molars. And also observed that 13% of cases primary tooth extraction is due to over retention and tooth type is canine, 11% due to mobility which is its time for exfoliation, and 9% of the cases the extraction of primary tooth is due to trauma. In some cases extraction is done for orthodontic purpose which accounts for 5% of cases, 55% of cases extraction is due to dental caries.

Conclusion: Since tooth extraction can cause difficultly to pediatric patients, the result is that to identity the various reasons of extraction of teeth and eliminate the cause prior to it and thus minimising tooth loss and it's expected adverse consequences.

Key Words*: Dental caries, Orthodontic purpose, Eliminate, Tooth loss, Retention*

Introduction

Oral health is an important component of both overall health and quality of life [1].Human beings have two successive sets of teeth primary and permanent, therefore they are better known as diphodonts [2]. Primary teeth are considered equally important as the permanent teeth. Primary tooth helps in chewing of food, speech, and esthetics and also acts as template for permanent teeth to assume proper position in dental arch [3]. Extraction of primary toothin a populations provide information about the prevalence of dental care, the availability of dental care, and attitudes towards extraction [4]. Preservation of both primary and permanent teeth in children is of great importance; this is because teeth are important for stimulating the development of the dental arches, maintaining normal occlusal relationship, and playing a role in speech development [5].Extraction of primary or permanent teeth is performed for several reasons, including caries, periodontal disease, orthodontic treatment, traumatic injures, treatment failure, tooth impaction or eruption. Caries is the most common reason for extractions in a majority of the younger age groups. Early loss of primary dentition can result in delayed eruption, drifting, tilting or malpositioning of permanent teeth, thus causing malocclusion. It may affect esthetics, mastication and speech. Loss of several teeth in children can results in psychological disturbances [6].

Extraction of deciduous canine or molars may leads to mesial drift of teeth behind the space and distal drift of anterior teeth, with resultant displacement of permanent teeth and centerline disturbance [7].Although the presence of dental caries in children has reduced considerably in recent years, caries continues to affect the children in the population. Other causes may include trauma, malposition, congenital disorders, and arch length deficiencies causing resorption of primary teeth [8]. The loss of primary teeth also predisposes crowding, rotation and impaction in the permanent teeth [9]. Three factors are important,

- Degree of crowding is directly related to rate and extent of space loss after deciduous tooth extraction.
- Type of tooth loss. Loss of one primary canine may cause centerline shift. Loss of a deciduous molar, especially the second may allow mesial drift of the first permanent molar.
- Age of the child. The earlier a tooth is lost, the greater the tendency for drifting of tooth [10].

Traumatic injuries can be considered as one of the common causes for a tooth to be extracted since traumatic injuries usually occur among young children immediately after tooth eruption [11]. It is important to understand the factors which cause such loss and relative contributions of caries, periodontal diseases, trauma and orthodontic consideration to develop the strategies for future the reduction in loss of deciduous tooth [12]. The retained deciduous teeth are teeth that are did not shed at the normal shedding time and showed insufficient root resorption for normal shedding six months after the loss of the corresponding tooth in the same mouth and usually associated with double primary teeth, hypodontia affecting permanent successors, and subsequent to trauma or sever infection of primary teeth; so extraction of these teeth is indicated to allow proper space for permanent tooth to erupt if it is present [13]. A better knowledge of the reasons for extractions can be a help to optimize dental care and treatment planning and thereby avoid painful events and the possible development of dental anxiety for children.

The purpose of this study was to investigate knowledge, attitude about the principles reasons for primary tooth extractions and tooth type most frequently extracted.

Materials and Method

This study was conducted by assessing the responses to 10 pre-tested multiple choice questions regarding the reasons for extraction among dental practitioners. The questionnaire was used to conduct the survey among dental practitioners, a total of one hundred and fifty dental practitioners were recruited in the study. The questionnaire based study was conducted among dental practitioners to obtain information about their knowledge, attitude about the reasons for extraction of primary tooth and the tooth type that being extracted during their dental practice.

The questionnaire comprised of 10 structured question used to collect the data concerning about their knowledge about the causes for extraction of primary tooth.

1. What's the ideal function of Primary teeth?
    a. Mastication
    b. Aesthetics
    c. normal development of occlusion in the permanent dentition
    d. All of the above.
2. Does paediatric patient seek dental clinic, most commonly for extraction?
    a. Yes. b. No
3. If yes, what is the most common factor that influence the extraction of primary tooth?
    a. Dental caries. b. Trauma. c. Mobility d. Over retention
    e. Orthodontic purpose. f. Other causes.
4. What do you think of other causes for extraction of primary tooth?
    a. Periodontal diseases
    b. Parents request.
    c. Some medical condition.
    d. Failure of pulp therapy
    e. All of the above
5. What is the most common type of tooth being extracted for dental caries?
    a. Incisor.
    b. Canine.
    c. Molar
6. What is the most common type of tooth being extracted due to trauma?
    a. Maxillary Incisors.
    b. Mandibular incisors
7. What is the most common type of tooth being extracted due to mobility?
    a. Maxillary Incisor.
    b. Mandibular incisors
8. What is the most common type of tooth being extracted due to prolonged retention of primary tooth?
    a. Incisors
    b. Canine
    c. Molars.

9. Do you think economic problem are also one of reasons for extraction of primary tooth?

   a. Yes. b. No

10. What is the most common arch that being extracted?

   A. Maxilla. b. Mandible

Results

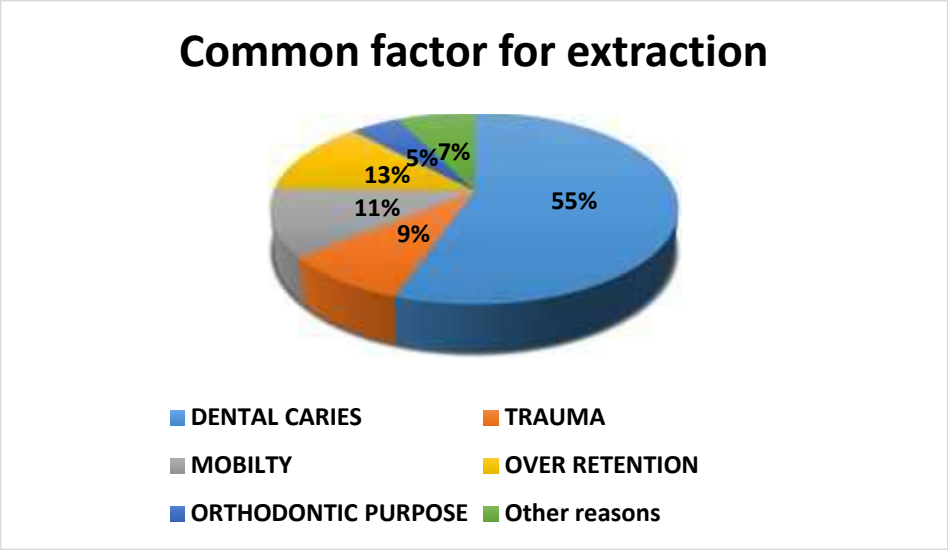

Figure 1: Common Reasons for Extraction of Primary Tooth

Figure 1: Illustrates about the extraction of deciduous tooth due to many reasons but possible reasons are due to dental caries [55%], over retention of primary tooth [13%], mobility due to exfoliation [11%], trauma [9%], other reasons [7%], for orthodontic purpose [5%]. Dental caries is the most common reason due to poor oral hygiene practices and habits.

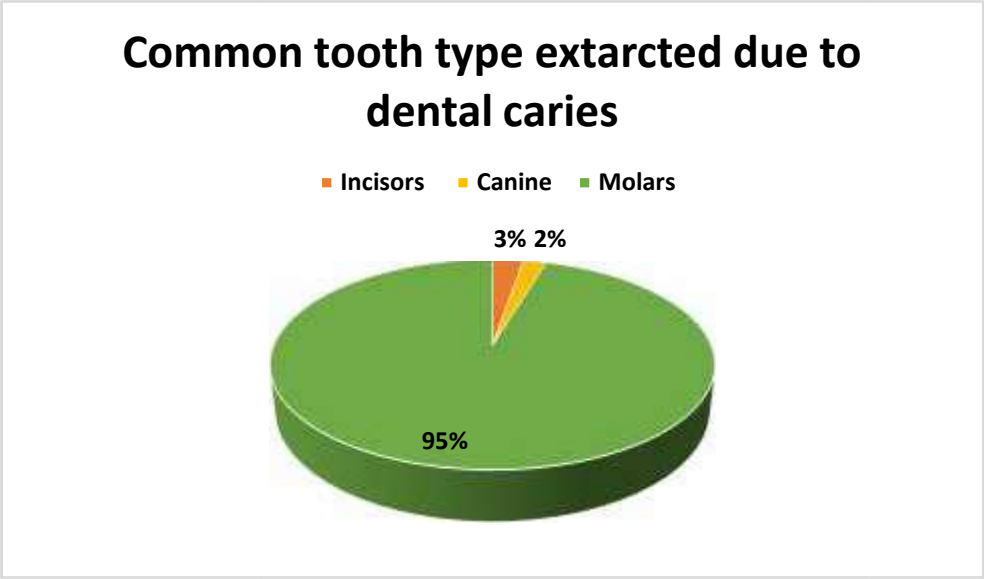

Figure 2: Common tooth type extracted due to dental caries.

Figure 2: Illustrates the most common tooth types extracted due to dental caries were molars [95%], incisors [3%], and canine [2%].The teeth at highest risk for carious lesions are the permanent first and second molars due to length of time in oral cavity and presence of complex surface anatomy.

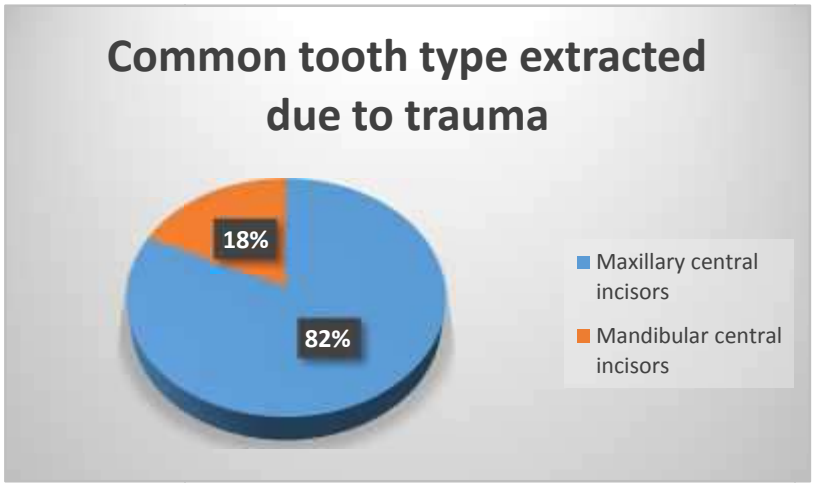

Figure 3: Common tooth type extracted due to trauma

Figure 3:Illustrates the most common tooth type extracted due to trauma maxillary incisors [82%] and mandibular incisors [18%]. Traumatic injuries can be considered as one of the common causes for a tooth to be extracted since traumatic injuries usually occur among young children immediately after tooth eruption.

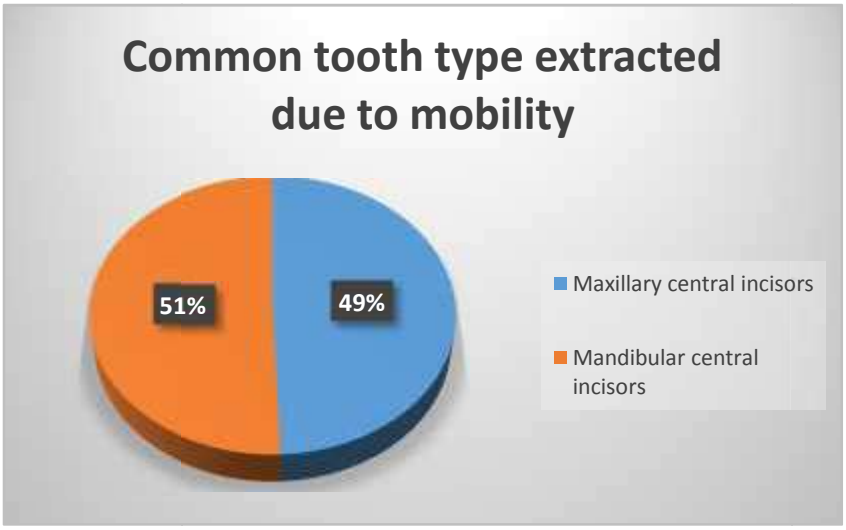

Figure 4: Common tooth type extracted due to mobility

Figure 4: Illustrates about the most common tooth type extracted due to mobility were maxillary incisors [49%] and mandibular incisors [51%]. Tooth extracted because of its mobility; time for exfoliation, thus the primary teeth will ultimately be replaced again with permanent teeth.

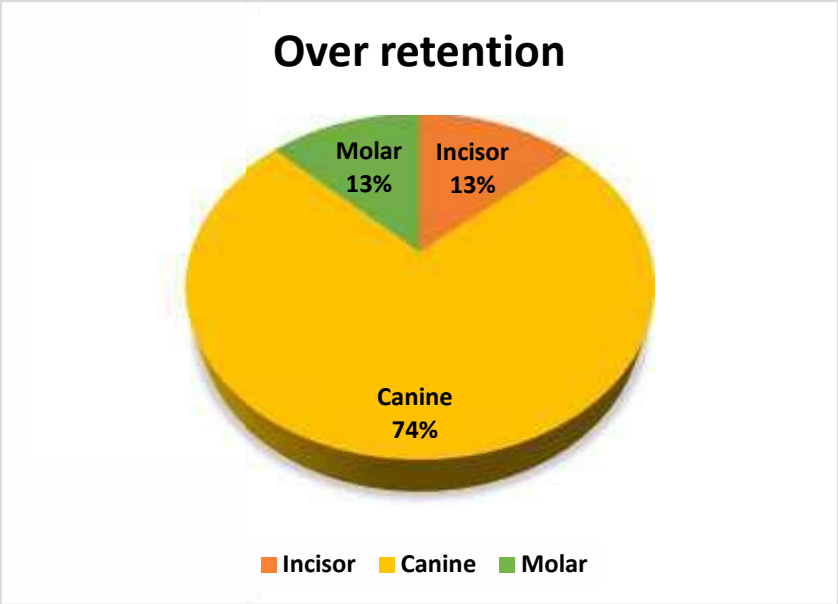

Figure 5: Illustrates about common over retained deciduous tooth.

Figure 5: Illustrates about the most common over retained primary tooth were canine [74%], incisors [13%], and molars [13%].Prolonged retention of primary teeth. Primary teeth may be retained for a variety of reasons, the most common being developmental absence of the permanent successor. Even when the permanent tooth is present it may fail to erupt leaving the deciduous tooth in situ. This can be a result of crowding, ankylosis of the primary tooth or the presence of supernumerary or other problems.

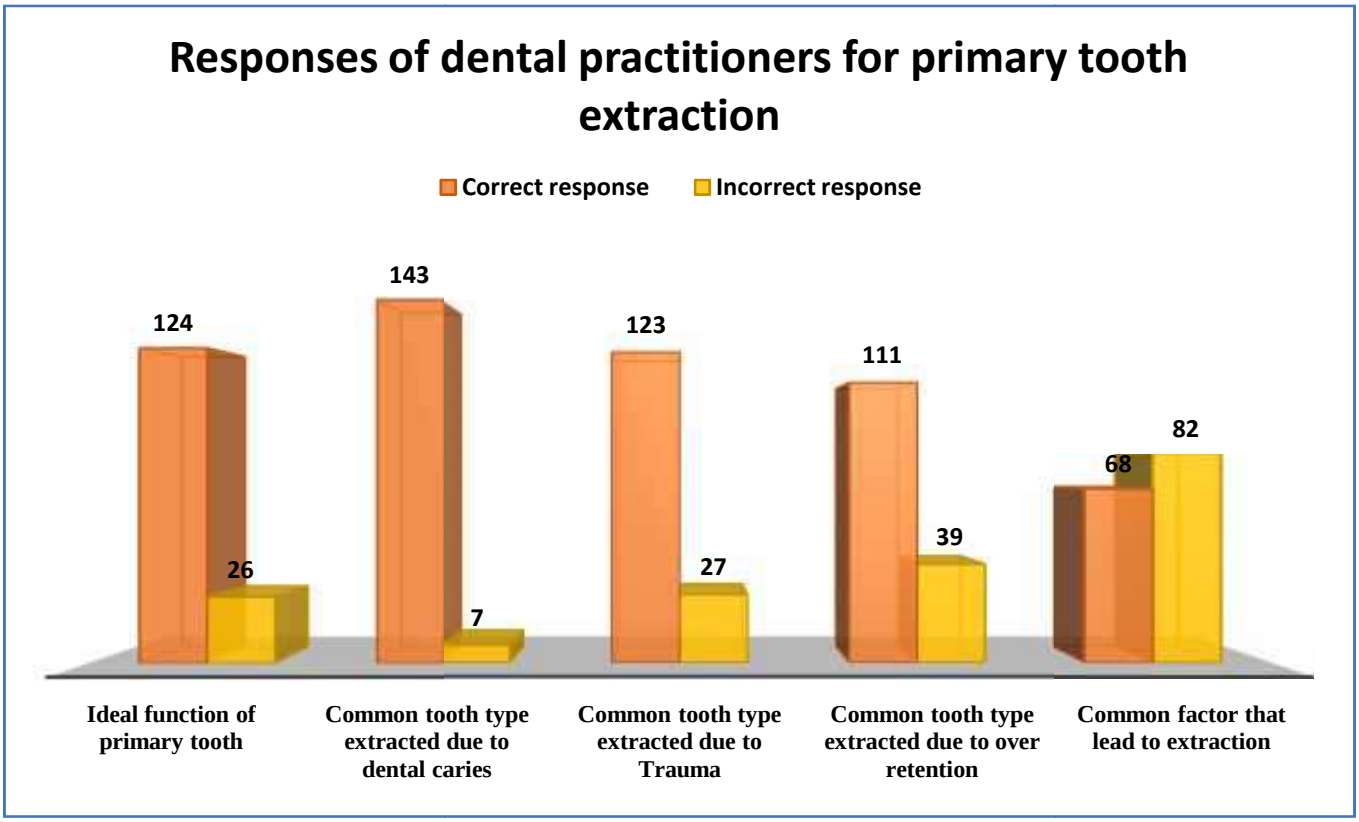

Figure 6: Illustrates about responses of dental practitioners for primary tooth extraction

On reviewing 150 questionnaire which is filled by the dental practitioners, it is observed that the most common reason for extraction of teeth is due to dental caries among other reasons and the common type of teeth extracted due to dental caries is molars. And also observed that 13% of cases primary tooth extraction is due to over retention and tooth type is canine, 11% due to mobility which is its time for exfoliation, and 9% of the cases the extraction of primary tooth is due to trauma. In some cases extraction is done for orthodontic purpose which accounts for 5% of cases, 55% of cases extraction is due to dental caries.

Discussion

Extraction of tooth is commonly a treatment consideration in the orthodontic management since the primary aims of orthodontic treatment in the mixed dentition are to correct dental arch

irregularities, occlusal and jaw relation abnormalities and to eliminate functional interferences; these may be classified as preventive which means the elimination of factors that may lead to malocclusion or interceptive that implies to the corrective measures which may be necessary to prevent a potential irregularity from progressing into a more sever malocclusion [14]. Tooth loss is considered as a crucial indicator of oral health status of the individual and the community at large [15,16]. Studies have shown that tooth loss strongly mirrors quality-of-life and nutrition intake of those affected and signal the onset of serious morbidity and disability [17,18]. Extraction of primary tooth in a population can provide information regarding the availability of dental care, the prevalence of dental disease, and attitudes toward tooth loss. There were many differences in the reasons for the extraction of different tooth types. Since very few extractions were due to periodontal disease, patient requests, or general medical reasons, these categories were come under other reasons. A better knowledge of the reasons for extraction can help to optimize dental care and treatment planning.

In our study, the most common factor for extraction are dental caries [55%], over retention of primary tooth [13%], mobility due to exfoliation [11%], trauma [9%], other reasons [7%], for orthodontic purpose [5%]. The most common tooth types extracted due to dental caries were molars [95%], incisors [3%], and canine [2%]. The tooth types extracted due to trauma weremaxillary incisors [82%] and mandibular incisors [18%]. The tooth type extracted due mobility were maxillary incisors [49%] and mandibular incisors [51%]. The over retained primary tooth were canine [74%], incisors [13%], and molars [13%]. For orthodontic purpose, the most common tooth types extracted were primary canine.

The factors which influencing the primary tooth extractions were many, which includes economic reasons which is due to the tooth could have been saved but the patient found the treatment is too expensive and also due to patient/parent request and periodontal diseases due to loss of function, periodontal abscess, pain and general medical reasons that is prophylactic extractions [19].

Several studies shown the data that the type of food consumed, feeding practices, snacking habits and pattern of dental visits have an important role in increasing caries level. The delayed visits to the dental clinic for routine checkup, and if the attendance is only promoted by symptoms; carious teeth are often treated by radical treatment which is extraction. Also, the lack of

awareness of the importance of daily brushing plays an important factor in increasing the prevalence of dental caries [21].

The reasons for primary teeth extraction varied between the different age groups.Mohitbansal et al., 2017 reported that primary maxillary central incisor was found to be the most affected tooth due to trauma [20]. It is similar to our study, maxillary central incisors [82%] were most common tooth type affected due to trauma than mandibular central incisors [18%]. Kuthyet al., 1994 reported that orthodontic considerations are more frequently the reason for extraction of deciduous canines, which is similar to our study. [21].

In our study it was found that primary maxillary and mandibular first molars were more affected due to caries, similar to Mohitbansal et al., 2017. Premature loss of a deciduous molar tooth due to caries also results in not only loss of function, but also can lead to increased possibility that the other teeth may drift [22]. This may influences the occlusion normal development and creates an increased need for orthodontic treatment [16].

People living in developing countries, and concomitantly, of lower socio- economic status have a lacunae in oral health awareness mirrored in their practice of oral hygiene habits [23]. Dental care has been systematically organised to improve dental health attitudes. This development has improved dental health and changed the dental caries patterns affecting them [24]. The high percentage of deciduous teeth loss could be due to the lack of knowledge among parents or a belief that the primary teeth will ultimately be replaced again. Prevention of caries in primary teeth must begin early in life to identify those at risk.Preservation of primary teeth is one of the major concerns for dentists. These teeth serve as a jewel which increases the smile and hence the self-esteem of the children.This shows the presence of poor maintenance of oral cavity in children.

Conclusion

Oral diseases have been a persistent public health problem globally, with almost every individual experiencing oral health problems at least once in their lifetime .Dental caries is observed to be the most frequent reason for extraction of teeth, this shows that there is poor oral hygiene maintained by children. Children usually face difficulty while extracting the tooth and also there

are post operative complication such as drifting off adjacent teeth, rotation and other causes. In order to prevent complications, it is applicable to create awareness and prevent tooth loss. It's important to understand how tooth loss occurs and take steps to prevent it through education, early diagnosis and regular dental care. The awareness should be created about their oral hygiene practices and habits. Parental oral health care education is essential to establish good oral health maintenance. Knowledge about oral health care among parents play an important role in maintaining oral hygiene and reducing the level of decayed tooth among children.

Abstract

Introduction: people of all walks of life. General health is incomplete with the maintenance of oral health. Good oral health care practice is an effective and preventive measure for maintaining good general heath. Oral health is an essential for good health throughout life. Poor oral health and untreated oral conditions and diseases can have a significant impact on quality of life.

Aim: The aim of the study was to assess oral health awareness among undergraduate medical students.

Materials and Method: The study was conducted among 100 undergraduate medical students. The pre-tested questionnaire with 20 structured questions were prepared and distributed to medical students to obtain information. The questionnaire comprised of questions based on the attitude, awareness towards the oral health among undergraduate medical students.

Results: In the present study, the awareness about oral health was found to be good among medical students. This survey found that 48% of students brush their teeth twice a day and 49% of students had regular dental visit. Out of 100 student's majority of them were answered for main cause of tooth decay were due to high sugar content, reduction in saliva level, reduction in fluoride level and some of them were answered due to high sugar content only.

Conclusion: The present survey shows good oral health awareness among undergraduate medical students, and final year students were found to have better knowledge compared to first, second and third year undergraduate students.

Key Words:*Knowledge, Attitude, Oral health, Hygiene, Fluoride level.*

Introduction

Health is a universal basic right and need for people of all walks of life. General health is incomplete with the maintenance of oral health [1]. Good oral health care practice is an effective and preventive measure for maintaining good general heath. Oral health is an essential for good health throughout life. Poor oral health and untreated oral conditions and diseases can have a significant impact on quality of life [2]. The oral hygiene care procedures are major component in children's health educational programs and incorporate a complex of activities, targeted to reduce and limit dental plaque accumulation. Majority of the population approaches medical practitioners for their oral health problems at primary health centre level. Hence, general practitioners should have an appropriate knowledge about oral health and also should play an active role in oral health promotion [3].The most common oral diseases, dental caries and periodontal disease, are considered to be behavioral diseases because adoption of healthy oral habits is crucial in controlling them. To a great extent, their prevention and control depend on a person's lifestyle and behavior [4].

Oral health can affect the most basic human needs, including the ability to eat and drink, swallow, maintain good nutrition, smile, and communicate. [5]. Medical practitioners should play an active role in oral health promotion [6]. Good knowledge of oral diseases is crucial in medical practice due to the following reasons (a) Periodontal diseases are associated with multiple systemic conditions of medical interest (b) A large number of systemic diseases have oral manifestation. (c) Many drugs are associated with oral adverse drug reactions and (d) majority of the population approach medical practitioners for their oral health problems [7].Dental caries and periodontal diseases can be effectively prevented by plaque removal, which serves as a standard to evaluate oral hygiene. Poor oral health has been proven to have unfavorable effects on general health.Hence, early screening and proper referral by these professionals may benefit to improve the access to oral health problems and to reduce the associated morbidity and mortality. The need of the hour is for general practitioners to have adequate knowledge about oral health as they are the one to whom majority of the population approach[8].The practices that help in prevention of oral diseases include tooth brushing; tooth flossing; use of fluoridated toothpaste for brushing and mouth rinsing and lower consumption of sugary foods and beverages. Periodic dental visits are a practice that helps in early detection and

prevention of dental diseases. Several factors influence compliance with oral hygiene practices among the children. Poor oral hygiene occurring due to increasing plaque and calculus deposits with increasing age has been diagnosed. Personal and professional plaque removal and professional calculus removal have been extensively available for prevention of gum diseases. In order to achieve oral health benefits, toothbrush and other oral hygiene aids should be used daily in a correct manner. Dental plaque will usually adhere on the surface of teeth. Exploration of literature reveals that only few studies have assessed oral health awareness among undergraduate medical students. So, the present study was conducted with an aim to assess oral health awareness among undergraduate medical students.

Materials and Method

The pretested questionnaire was used to conduct the survey in medical college, a total of 100 students were recruited in the study. The questionnaire-based study was conducted among students of Saveetha medical college which is located in Chennai, India. The data collected concerned the oral hygiene awareness and attitude, dental complaints and previous visits to dentists. The target population comprised of 100 students, female and male was 53 and 47 respectively.

The questionnaire comprised of 20 pre-tested questions. The questionnaire comprised of questions based on the attitude, awareness towards the oral health among undergraduate medical students. Participants knowledge was gathered about tooth cleaning, brushing and dental problems were asked for practices of oral health. One of the factors that is responsible for someone attitude and behavior is knowledge. Knowledge can be described as level of understanding of an individual towards facts, information, skills and many more.

A self made ended questionnaire written in English language was given to each one of the undergraduate medical student. The questionnaire included information related to name, age, and sex. The questionnaire was further categorized to evaluate the awareness of oral hygiene among medical students.

1. Proper oral health care practice is an effective and preventive measure for maintaining good general health.

   A) Agree B) Disagree C) don't know

2. If agree, what are the diseases which are related to oral health

   A) Heart disease and stroke

   B) Respiratory disease

   C) Gastrointestinal problems

   D) All of the above

   E) None of the above

3. How often do you visit a dentist?

   A) Once a year

   B) Once in 6 months

   C) Infrequently

   D) More often

4. What is the reason for visiting a dentist?

   A) Tooth ache

   B) Regular checkup

   C) Control

5. How often do you brush your teeth?

   A) Once a day

   B) Twice a day

   C) More than twice a day

6. Do you think you know how to brush your teeth properly?

   A) Yes B) No C) Don't knows.

7. How long do you use the same tooth brush?

   A) Less than 3 months

   B) 3 – 6 months

   C) More than 6 months

8. What else do you use besides your tooth brush and paste?

   A) Mouth wash

B) Interdental brush

C) Dental floss

D) Tooth brush only

9. Use of fluoridated tooth can prevent tooth decay?

A) Agree

B) Disagree

C) don’t know

10) What is the main cause for tooth decay?

A) High sugar content food products

B) Reduction in saliva level

C) Reduction in fluoride level

D) All of the above

11) Which among the following brushing technique do you use while brushing?

A) Horizontal strokes

B) Vertical strokes

C) Circular strokes

D) Both vertical and horizontal strokes

12) In hospitalized patients, what is the common dental complaint do you come across?

A) Bleeding gums

B) Ulcers

C) Oral halitosis

D) Don’t know

13) What does bleeding gums means?

A) Gums are unhealthy

B) Ulcerated

C) Gums are infected

D) Don’t know

14) What are yellow or greenish yellow deposits near the gums?

A) Food deposits

B) Plaque

C) Calculus

D) Don’t know

15) What are the oral health’s problems occur to person with tobacco chewing habits?

A) Mouth ulcers

B) Oral cancers

C) All of the above

D) Don’t know

16) Cheek and lip biting may increase the chances for oral health?

A) Agree

B) Disagree

C) don’t know

17) Smoking or using tobacco products increase the chances for tooth loss?

A) Agree

B) Disagree

C) don’t know

18) Do you think oral cancer can affect general health?

A) Agree

B) Disagree

C) don’t know

19) What do you think for cause of oral cancer?

A) Usage of betel nut and betel quid

B) Usage of tobacco

C) Smoking

D) Don’t know

20) Do you think use of tongue cleaner would damage the taste buds?

A) Agree

B) Disagree

C) Don’t know

Result

In the present study, the awareness about oral health was found to be good among undergraduate medical students.

Proper oral health care practice is an effective and preventive measure for maintaining good general health, the results among undergraduate medical were 100% agreeable that oral health plays an essential element in health of an individual, poor oral health and conditions can have a significant impact on quality of life.

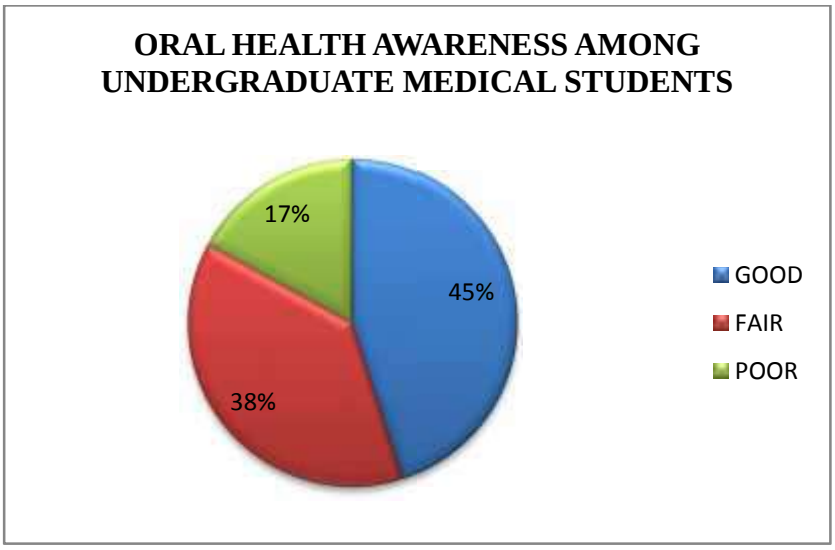

Figure 1: Awareness about oral health

Figure 1 shows that, only 45% were found to have good oral health awareness, 38% of students were found to have fair oral health awareness and 17% were found to have poor oral health awareness. Out of 100 student's final year medical students have good oral health awareness when comparing to third year students. And the third year students have fair oral health awareness comparing to first and second year students. The probable reasons could be more clinical exposure, more experience and knowledge of final year undergraduate students when compared to second and third year students.

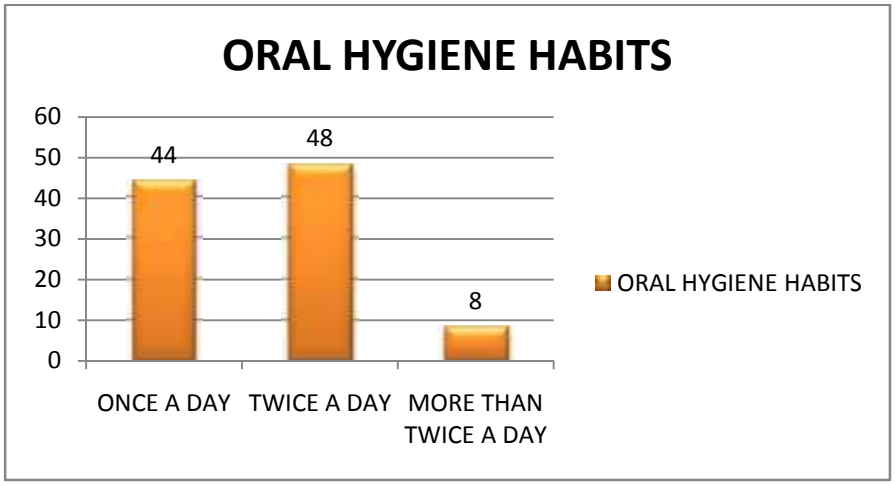

Figure 2: Oral hygiene habits

Figure 2 shows, 48 students have oral hygiene habits of brushing twice a day and 44 of them brush once a day and 8 of students brush more than twice a day due to some reasons. Brushing at least twice a day has shown a decrease in dental caries incidence [9].

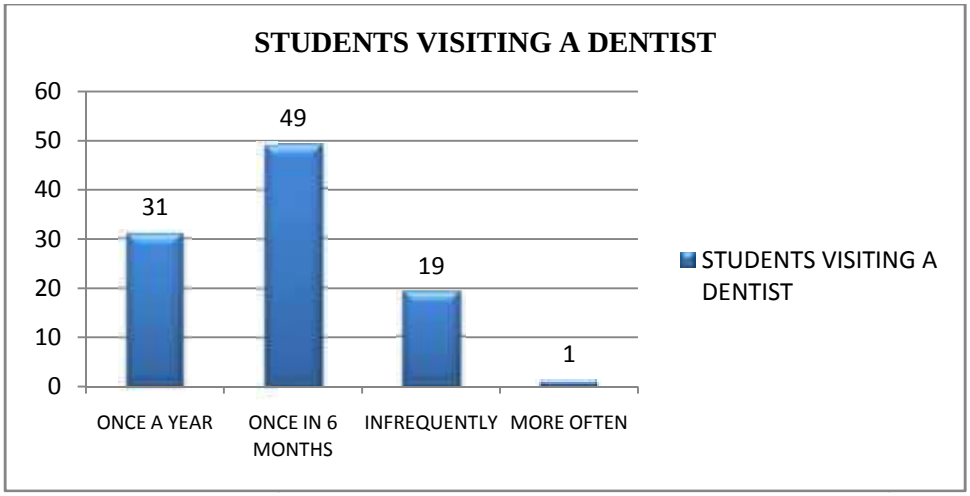

Figure 3: Regular dental visit

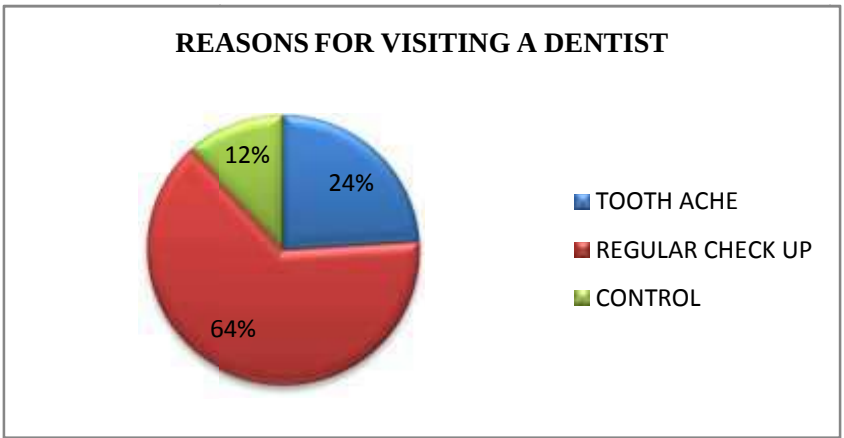

Figure 4: Reasons for dental visit

Figure 3 and 4 shows, 49 students were visiting dentist once in 6 months for their regular checkup and some of the due to tooth ache or some other reasons, 31 of them visiting once a year and 19 of them infrequently visiting a dentist. Medical students should be aware of the oral health problems and should understand the causative agents. In order avoid such oral health problems; they should have periodic visiting to dental hospitals. In here 64% of students visiting dental hospital for regular periodic checkup, 24% students due to dental caries and tooth ache and 12% visited dental hospital for control measures of oral diseases.

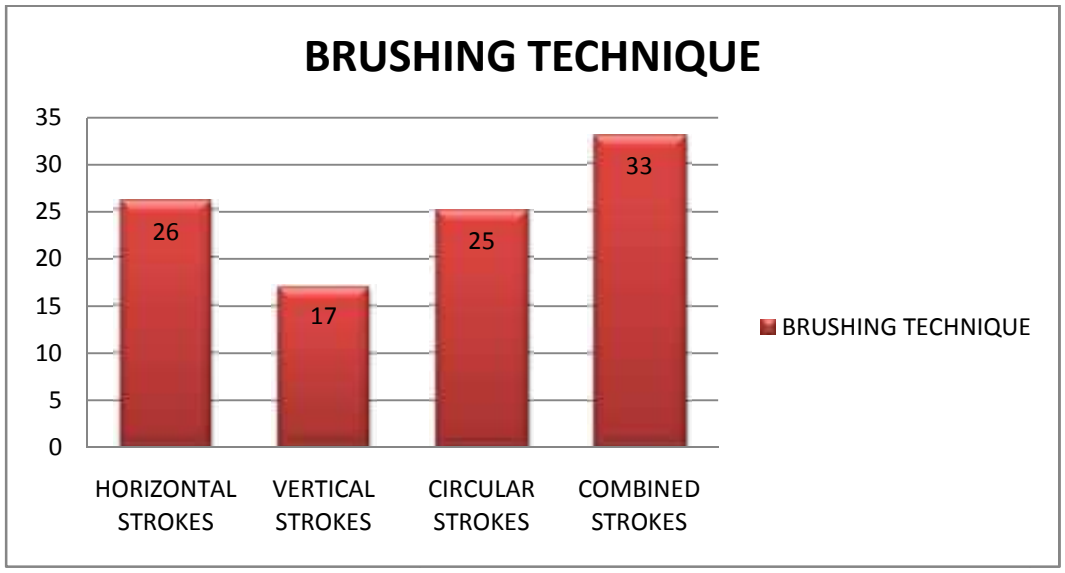

Figure 5: Brushing technique

Figure 5 shows, most of them were using combined strokes as brushing technique, and 26% of them were using horizontal strokes, 25% of them were using circular strokes and 17%of were using vertical strokes as their brushing technique.

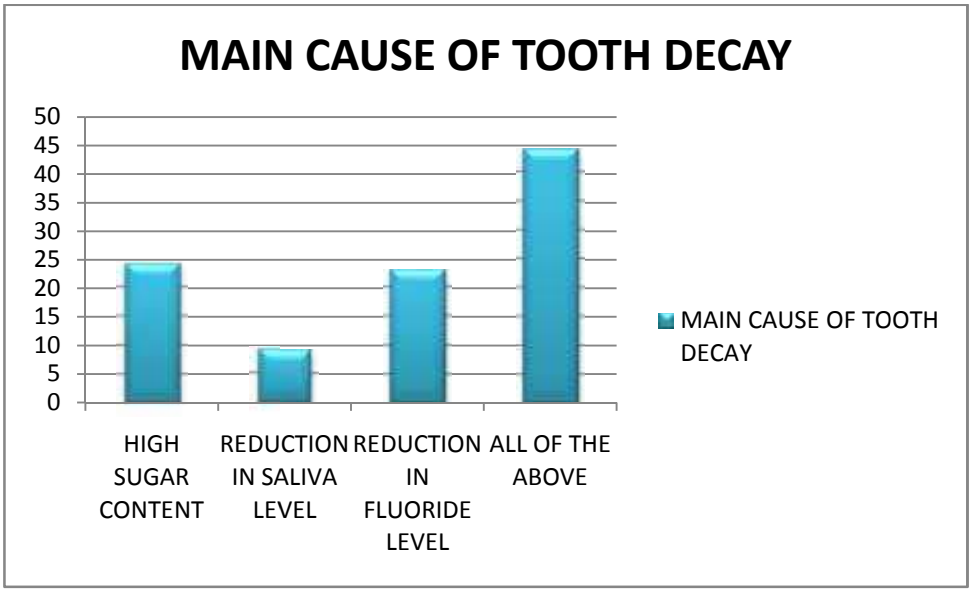

Figure 6: Main cause of tooth decay

Figure 6 illustrates that most of the medical students, 24% of them were answered as main cause of tooth decay due to consuming high sugar content products, 9% of them told reduction in saliva level, 23% were answered reduction in fluoride level and 44% of them mentioned all the above reasons were the reasons for the main cause for tooth decay.

Discussion

People living in developing countries, and concomitantly, of lower socio- economic status have lacunae in oral health awareness mirrored in their practice of oral hygiene habits[10]. Dental care has been systematically organised to improve dental health attitudes. This development has improved dental health and changed the dental caries patterns affecting them[11]. For preserving oral health and for preventing oral diseases oral self care such as tooth brushing and flossing are important [12]. Regular dental visit is an important aspect of maintaining good oral health [13].

Pattern of oral health behavior in medical graduates, their beliefs, and attitudes play an important role in knowledge they impart to the general public and their community [14]. Oral health is an essential component of general health and overall well-being of an individual. Oral cavity and its surrounding structures that are free of any diseases is indicative of good oral health. This not only makes a person look and feel good, it is equally relevant in maintaining oral

functions [15, 16]. Moreover, medical students are far more likely to encounter underserved and vulnerable populations than dental students [17].

In this study, 45% were found to have good oral health awareness, 38% of students were found to have fair oral health awareness and 17% were found to have poor oral health awareness. Out of 100 student's final year medical students have good oral health awareness when comparing to third year students. And the third year students have fair oral health awareness when comparing to second and first year students. The probable reasons could be more clinical exposure, more experience and knowledge of final year undergraduate students when compared to second and third year students.

In this questionnaire-based study, out of 100 student's majority of them were answered for main cause of tooth decay were due to high sugar content, reduction in saliva level, reduction in fluoride level and some of them were answered due to high sugar content only.

Many of the first-year undergraduate medical students were found to have average oral health awareness when compared to second and third year undergraduate medical students in which most of them had poor oral health awareness.

The reason could be medical students are exposed to dental subjects in their second academic year. First year undergraduate medical students were not included in the study as they do not have any clinical exposure and experience. It is recommended that oral health awareness of the undergraduate medical students can be improved by incorporating basic information about oral health in their academic curriculum, conducting various inter-disciplinary workshops and conferences, increasing the clinical exposure of the students to oral findings as most of the systemic diseases manifests in the oral cavity, special study modules or electives in oral health and disease should be created by involving the dental faculty, emphasizing the importance of oral health. Thus, oral health care needs to be addressed by the combined efforts of dental and medical professionals and should be integrated into comprehensive health-promoting strategies and practices [18,19]. This has been attributed to the positive self care attitudes for internal psychological reasons to improve their appearance and self-esteem[20].

As prospective doctors - they should have sufficient awareness about oral health as oral health problems are cumulative by nature, more amenable to prevention and difficult to treat.

Early identification of the oral diseases and referral to a specialist not only prevents a patient from pain, agony, functional and esthetic problems, but also from death in some conditions.

Conclusion:

The present survey shows good oral health awareness among undergraduate medical students, and final year students were found to have better knowledge compared to first, second and third year undergraduate students. Medical practitioners should play an active role in oral health promotion. Proper knowledge of oral diseases is crucial in medical practice. The knowledge they are going to acquire at present will be reflected in the future during their practice. Awareness makes maintenance of optimum oral health important in one's life. Medical students adapt the knowledge acquired at undergraduate level which influences their orientation of medical practice and patient care after their graduation. Implementation of oral health programs among medical students will not only improve their personal oral health care, but also potentially influences the motivation of patients to follow the preventive oral health measures. It also forms an essential basis for promoting the importance on primary oral health care.

Assessment of Impaction Pattern of Mandibular Third Molars:-A Radiographic Survey

S.Jayakeerthana[1],R.Navaneethan[2],Nabeel Nazar[3],
Graduate Student[1],Reader[2], Department of Orthodontics,Reader[3], Department Of Oral and Maxillofacial Surgery,
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Third molars are known as wisdom teeth as they erupt after 18 years of age. In a lot of individuals they fail to erupt onto the oral cavity owing to a variety of reasons, the most common being lack of space in the dental arch.The aim of this study is to assess the pattern of Mandibular third molar impactions using the Orthopantomograph (OPG's)**.**

Material and Methods: OPG's of 150 patients (91 female and 59 male)who were between 18-25 years of age and had impacted mandibular third molars was assessed for gender, side of the mandible having greater frequency of impaction and the pattern of impaction of the third molars.

Results: Bilateral impaction (26.66%) was more common than and particular left (23.33%) or right (19.33%) unilateral impactions.The mesioangular pattern of impaction was more common in both male and female and was followed by distoangular, vertical and horizontal patterns.

Conclusion: The study showed that there was no gender predilection in the presence of impacted mandibular third molars and that the mesioangular pattern of impaction was more common.

Key Words: *Mandibular third molars, impacted teeth, Orthopantomograph, Mesioangular Impaction, Gender predilection.*

Introduction

Impaction is defined as a completely or partially unerupted tooth and positioned against another tooth, bone or soft tissue,so that its further eruption would be unlikely(1). Third molars are also known as wisdom teeth as they erupt in the late adolescence or even in adulthood. Since they are the last teeth to erupt they are frequently impacted due to the lack of space in the dental arch. Impacted wisdom teeth are teeth which do not fully erupt into the mouth because of blockage from other teeth (impaction).

Owing to the fact that at least one impacted third molar can be traced in 33% of the general population (2,3), impacted third molars especially the mandibular third molars, constitute a common cause of pain and inflammation in the oral region. The high prevalence of their impaction has been attributed to a remarkable variety of factors, among which are inadequate retromolar space, unfavorable path of eruption, malposition of the tooth germ and hereditary reasons (4).

Impacted third molars are associated with numerous complications, such as pericoronitis, periodontal pathology or root resorption of the adjacent tooth, caries, cystic or neoplastic lesions, orthodontic or prosthetic problems and temporomandibular joint symptoms (5,6). Majority of patients who undergo a surgical extraction of an impacted third molar suffer from pain, swelling, trismus and general oral discomfort during the first postoperative days. The other less frequent complications arealveolitis, infection, hemorrhage and nerve injury (7).The aim of the study is to assess the pattern of impaction of the mandibular third molars.

Various classifications have been given on impacted teeth such as WINTER'S classification, PELL AND GREGORY'S classification, KILLEY AND KAY, ARCHER'S classification of impacted maxillary teeth, etc. Winter's classification is classified based on the inclination of the impacted tooth to the long axis of the second molar into distoangular, mesioangular, horizontal, vertical and transverse. This classification is used for the study as it is simple and easily understandable.(16) The aim of this study is to evaluate the positionof impacted third molars and also to evaluate the most common sex affected using the Winters classification. (17)

Impacted third molars can also be classified according to their angular relationship to the adjacent second molar. Angulation of the impacted third molar can be determined by evaluating the angle formed between the intersected longitudinal axes of the impacted third molar and the adjacent second molar, as described by Winter, either visually or by using an orthodontic protractor.

Materials and Methods

The impaction pattern of the mandibular molars was studied using Orthopantomograph (OPG). OPG’s of 150 patients who had impacted mandibular third molars were used for the study. The patients included in the study were between 18-25 years of age, with a mean age of 21.5 years.The pattern of impaction is derived by measuring the angles formed between the lines intersecting the long axis of the second and third molar. The angle formed is used to determine the mesial, distal, horizontal and vertical inclination in relation to the second molar.

The radiographs were interpreted for the following:

a) Unilateral or bilateral impaction of the mandibular third molar.
b) Pattern of impaction of the mandibular third molar.
c) Gender difference.

Results:

The results have been tabled in the tables 1-6.

Table 1: Gender distribution

Gender	N	Percentage
Male	59	39.33
Female	91	66.66
Total	150	100

Table 2: Distribution of mandibular impaction in the sample

Side Affected	Frequency	Percentage
Left Side Only	35	23.33
Right Side Only	29	19.33
Both Sides	40	26.66
Erupted	46	30.66
Total	150	100

Table 3: Gender distribution pattern of impaction on right quadrant in female patients

Right Mandibular Third Molar	N	Percentage
Absence	29	31.9
Mesioangular Impaction	29	31.9

Distoangular Impaction	19	20.9
Vertical Impaction	6	6.5
Horizontal Impaction	7	7.6
Total	91	100

Table 4: Gender distribution Pattern of Impaction on right quadrant in male patients

Right Mandibular Third Molar	**N**	**Percentage**
Absence	17	28.81
Mesioangular Impaction	20	33.89
Distoangular Impaction	8	13.56
Vertical Impaction	5	8.47
Horizontal Impaction	9	15.25
Total	59	100

Table 5: Gender distribution pattern of impaction on left quadrant in female patients

Left Mandibular Third Molar	**N**	**Percentage**
Absence	21	31.5
Mesioangular Impaction	35	23.3
Distoangular Impaction	12	18
Vertical Impaction	10	15

Horizontal Impaction	12	18
Total	90	100

Table 6: Gender distribution pattern of impaction on left quadrant male patients

Left Mandibular Third Molar	N	Percentage
Absence	25	37.5
Mesioangular Impaction	22	33
Distoangular Impaction	7	10.5
Vertical Impaction	4	6
Horizontal Impaction	9	13.5
Total	67	100

Discussion

Out of a total number of 150 OPG's used in the study, 59 were of males (33.33%) patients and 91 were of females (66.66%) patients (Table 1). A significant difference was seen in unilateral and bilateral distribution of third molar impaction. Unilateral impaction was found in 64 radiographs which accounted for 43% of the total and bilateral impaction was seen in 40 people which accounted for 26.6% of the sample (Table 2).

The mesioangular pattern of impaction was more common and was followed by distoangular, vertical and horizontal patterns. Third molar impactions were more common in the right quadrant (34% percent for the males and about 39% for the females) than in the left quadrant (23.3% in females and 33% in males). There's no sexual predominance seen in impaction pattern or agenesis (Tables 3-6). These findings are similar other studies done in different populations(8,9,10,11).

The main factor for third molar impaction is the lack of space for eruption. The early man ate coarse uncooked food that resulted in attrition of teeth on the occlusal and proximal surfaces of the teeth. This attrition and tendency of mesial drifting of the teeth provided the space required for the eruption of the third molars. Whereas, in modern man, the attrition of teeth

does not take place due to cooked and soft textured food and hence as a result the space required for third molars eruption by attrition and mesial drifting of teeth is lost (12-15).

Other factors that bring about impactions include the growth of the face, size of jaw, tooth size and food habits, overlying bone or soft tissue or with the host having systemic diseases etc. A properly positioned third molar erupts between the ages 18 and 24. The other complications seen with late eruption of the third molar and third molar impaction include incisor crowding, resorption of roots of adjacent tooth, inflammatory process and TMJ dysfunction.

The distribution of angulation and depth of impaction in the impacted lower third molars seen in this study is similar to that noted by Kramer and Williams. (18-19) They reported that 75% of impacted lower third molars were in mesio-angular and horizontal angulation. The angulation of an impacted tooth against the second molar has potential clinical implications, as outlined by Yamaoka et al. (20,21)

Conclusion

The following are the conclusions derived from the study,

- Bilateral impaction of mandibular third molar was more common than unilateral impaction
- Mesioangular impaction was the most common type of impaction and it was more common in males than in females followed by horizontal and vertical impaction.
- Agenesis was more common in females than in males.

Abstract

Introduction: Mentally challenged patients being treated by oral health care professionals is becoming common these days. As these patients should be treated with utmost patience and care, it is understandable that concern exists about the practitioner's attitude, confidence and skill levels in recognising and treating this group of patients.The purpose of this study is to assess the attitude, knowledge and confidence of oral health care professionals in treating mentally challenged patients.

Materials and Methods:A questionnaire based cross-sectional study is conducted among 430 oral health care professionals of Saveetha dental college. A questionnaire consisting of 15 validated questions was personally distributed to the oral health care professionals and their responses were collected.

Results:The attitude of oral health care professionals us good whereas they exhibit average knowledge and low confidence level in treating these group of patients.

Conclusion:Educating and training oral health care professionals should be emphasised in dental schools, so that they can manage these patients confidentially and skilfully in their general practice.

Key Words: *Mentally Challenged Patients, Attitude, Awareness, Knowledge, Oral health care professionals*

Introduction

Mental disorders affect more than 25% of all people at some time during their lives.People tend to have strong beliefs about the mentally ill, and many of these concepts are based on prevailing local systems of belief. Social stigma and negative attitudes can affect the quality of life for people with mental illness. Lack of accurate information about mental illness, lack of contact with individuals with mental illness and lack of familiarity might be one of the most important reasons of these. Educating people may have positive impact on this prejudice. [1], [2]Such negative attitudes may be detrimental not only to the patient care but also to the society's attitude to psychiatric disorders if they are present in the health professionals [3]. The knowledge of the attitude and awareness of the undergraduate medical students toward psychiatry, mental health and psychiatric disorders is of utmost importance as these individuals are going to be involved in the care of these patients either directly or indirectly during the later years of their careers. Psychiatry as a discipline is felt to be given a prime importance at the undergraduate levelwhich is reflected in the number of lectures in psychiatry andnumber of hours of psychiatry clinical posting. The present study aims at understanding the attitude of the oral health care professionals toward psychiatry, mental health, psychiatric disorders and their treatment.

Materials and Methods

A questionnaire based cross-sectional study is conducted among 430 oral health care professionals,which includes undergraduate interns, postgraduate students and teaching faculty of Saveetha dental college from November 2016 to December 2016. Ethical committee clearance was obtained. A questionnaire consisting of 15 validated questions was personally distributed to the oral health care professionals.Subjects were explained about the aims and objectives of the study being conducted in detail. Informed consent was taken after ensuring confidentiality of the information gathered in the questionnaires being used and clarifying that it would only be used for the purpose of the research intended. Their responses were collected and statistical analysis was done.

Research Proforma

a)Yes b) No

If yes, specify

- UG

- PG

15) If given an opportunity to work with these group of patients over a fixed period for training, will you render your dental services?

a)Yes b) No

Results

A total of 430 oral health care professionals participated in this study, 117 males and 313 females, out of which 139 were interns (under graduates), 170 were post graduates and 121 were teaching faculties. They were categorised under three age groups, 21 to 25 yearsold-229 candidates, 26 to 30 years old-107 candidates and above 30 years old-94 candidates. (Table 1)

Table 1: General characteristics of the candidates

Characteristic	N
Age	
21-25	229
26-30	107
>30	94
Gender	
Male	117
Female	313
Education	
Interns(UG)	139
PG	170
Faculty	121

In this study, 74% were aware that mentally challenged patients come under the category of patients with disability, 52% were aware of the spectrum of mental disorders, only 25% were aware of the percentage of mentally challenged patients requiring dental treatment in their locality, 7% has people with mental disability in their circle, 61% were interested in providing oral care for these group of patients, 66% were interested in being a part of

community health services rendering treatment for these group of patients, 27% were confident in delivering basic oral care for these group of patients, 26% were confident to manage any complications while treating these group of patients, 80% were comfortable in referring these patients to concerned specialists, 73% were willing to render their dental services, over a fixed period of training and 20% were trained to manage these patients in their course. (Table 2)

Table 2: Attitude and Knowledge of Oral Health Care Professionals in Treating Mentally Challenged Patients

S.NO.	STATEMENT	RESPONSE	FREQUENCY (%)
1.	Mentally challenged patients come under the category of patients with disability	Yes	74
		No	26
2.	Awareness of the spectrum of mental disorders	Yes	52

		No	74
9.	Comfortable in referring these patients to concerned specialists	Yes	80
		No	20
10.	Willingness to render their dental services, over a fixed period of training	Yes	73
		No	27

11.	Trained to manage these patients in their course.	Yes	20
		No	80

Limitations

This study was not without any limitations. Sample size was quite largecompared to other studies done related to attitude of health care professionals in treating mentally challenged patients. Furthermore, the participants were selected from only one institute, generalization of the results is difficult. Cross-sectional nature of the study and absence of any control groups might not have served our purpose of assessing the attitude and ascertaining the importance of undergraduate education in Psychiatry. Some observed differences on groupwise and sex-wise comparison may be attributed solely to the cohort effect.

Discussion

Stigma appears in the students who lack knowledge, adopting negative attitudes and avoiding certain group of people, usually with mental illness [4]. Despite of the burdens of the mental illness, some societies continue to hold deep-rooted, culture sensitive and negative beliefs about mental illnesses. The theory of classical labeling focus on stereotyping and rejection of others which may lead to social exclusion and demoralization [5]. This group of people usually show the impairment in cognitive, emotional and behavioral aspects. Due to this the patients are significantly less willing to interact with general population and sometimes it creates loneliness to patient or it may leads to violent behavior towards others who are less willing to interact with them [6]. Due to this stigma and discrimination the people with mental illness face difficulties in social relationships, experience social isolation, social withdrawal, social distance, homelessness, unemployment and institutionalization [7]. The patients with mental illness are considered as labeled persons. The concept of stigma has been divided into four components: labeling, stereotyping, separation, status loss and discrimination. Labeling involves categorizing the people in different groups. Stereotyping involves the association of labels with negative attributes. Separation is itself used to justify the association of negative attributes to labeled persons. Finally these three leads to loss of status and an experience of discrimination by the labeled person. The four components are interconnected with each other [8]. To overcome this stigma and discrimination from decades is to support and change the tools of institutionalization. Lack of knowledge and awareness

among the students is associated with the negative attitudes towards mental illness in the community. Various health professionals have to conduct awareness camps at initiative levels like schools and universities. Attitude is a hypothetical construct that represents an individual's like or dislike for a living or non living thing, which may be positive, negative or neutral. It originates from judgments and has affective, behavioral and cognitive components. [9] It also determines orientation towards a particular environment. [10] So, orientation of the oral health care professionals towards management of psychological problem in physically ill patients during medical training shapes their attitude towards mental illnesses as a disease. In the debate about changing social attitude, the issue is whether a positive change in attitude also leads to an improvement in anti stigmatizing behaviour. Theories about behavioural change and learning vary as to whether knowledge gained through extrinsic reinforcement, eg.Grades or positive remarks [11]. In social learning theories or cognitive theories, attitude change is seen as dependent on personal factors, environmental factors and attributes of the behaviour itself [12]. In the ecological learning model, behaviour change is effective if it occurs on multiple levels: interpersonal factors, group factors, institutional factors, community factors and public policy [13]. Long lasting attitude change is thus a complicated matter. Previous results from research in the area of attitudes towards mental illness found somewhat divergent results. Some researchers claim that changing prejudicial attitudes towards persons with mental illness have a direct influence on discriminatory behaviour [14]. Broad educational approaches aimed at changing inaccurate stereotypes about mental illness have shown to be effective in producing a short term improvement in attitudes [15].

The current study made use of a questionnaire based survey methodology to assess the attitude of oral health care professionals.The attitude of oral health care professionals us good whereas they exhibit average knowledge and low confidence level in treating these group of patients. A similar study done by Neeli Uma Jyothi et al showed neutral attitude of the participants in treating these patients. A study done by Peter Baghurst et al and Lisa et alshowed the attitude towards mental disability changed after the students attended a training program for treating mental disabilities [16] [17].Encouraging and actively involving the students in educational programs, organising camps and creating awareness towards managing mentally challenged patients should be done[18].As more dental schools utilise community based clinical experiences to increase student's exposure, it is important that these experiences provide exposure to these group of patients.Other similar studies by Chou and Maket al, Chung et al, Wolff et alhave shown that, general practitioners or oral health

care professionals who have previously treated these group of patients have shown more positive attitude towards mental illness [19] [20] [21]. A study done by Loan P. et aloral health care professionals did not think their undergraduate dental education had prepared them well to treat mentally challenged patients [22].Major efforts need to be made to improve dental education concerning these patient groups.A study done by Raymond et al, showed an average comfort level and willingness to treat special care needs patients and vulnerable populations [23].It is obvious that providing knowledge and skills basis will improve dentists attitude towards treating these patients and will give more confidence. Such positive attitudes may then allow them to think about overcoming obstacles that may keep them from treating these patients.

Conclusion

The oral health care professionals had multiple lacunae in their knowledge toward psychiatry, psychiatric disorders, psychiatric patients and psychiatric treatment. The possible reasons could be many. But a potential contributory fact could be the neglect of psychiatry as a discipline at the undergraduate level. The lesser number of hours assigned to psychiatry at this level could add to the cause. Subjects such as psychiatry are underrepresented during this training. It has been felt that psychiatry remains a neglected subject during the undergraduate training [22]. Thus, there is a need to relook into the curricula of the undergraduates and possibly a few solutions could be reached at. Overall attitude towards mental illnessamong the oral health care professionals is good whereas they exhibit average knowledge and low confidence level in treating this group of patients.A further study with oral health care professionals from different institutional backgroundis needed to get a detail nationwide picture that canbe implemented in future academic and professionalpractice.

Attitude and Perception of Undergraduate Dental Students towards Endodontics as a Specialty

S. Mohamed Jaqfer Sadiq[1], Jayalakshmi Somasundaram[2], Aarthi Vignesh[3],
Graduate Student[1],Senior Lecturer[2],Department of Conservative Dentistry and Endodontics,
Senior Lecturer[3], Department of Oral and Maxillofacial Surgery,
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Students attitude toward choosing a specialty subject for post graduate studies is of great importance for the education system. The scope of endodontics has broadened vastly in recent years.CBCT, MRI, Doppler's, PCR in diagnosis and the treatment planning for oral lesions of pulp and periapical origin, Nonsurgical approach for root canal therapy, microsurgical procedures for removal of pathologic tissues with minimal intervention are the various types of advancement introduced in Endodontics.

Materials and Methods: A questionnaire study survey consisting of 10 multiple-choice questions was compiled and distributed among 100 undergraduate dental clinical students studying in Saveetha dental college. A pilot study was conducted to check the feasibility and reliability of the questionnaire.The main domains appraised were preclinical and clinical training in endodontics, their opinion and knowledge in endodontics as post-graduate specialty.

Result: Total number of undergraduate students participated in the study were 100. 92% of the students participate think endodontics as one of the major branch in dentistry concerned about estheticswhereas the remaining 8% disagreed to it.

Conclusion: This study concluded that most of the undergraduate students are interested in persuading endodontics as a specialty for post-graduation. Thus it needs more emphasis on preclinical endodontic training and clinical training for management of all pulpal and periapical lesions with different modalities at the undergraduate level.

Key Words: *Endodontics, Post-Endodontic rehabilitation, 3-D Endodontics, Rotary instrumentation.*

Introduction

Students attitude toward choosing a specialty subject for post graduate studies is of great importance for the education system. The scope of endodontics has broadened vastly in recent years.CBCT, MRI, Doppler's, PCR in diagnosis and the treatment planning for oral lesions of pulp and periapical origin, Nonsurgical approach for root canal therapy, microsurgical procedures for removal of pathologic tissues with minimal intervention are the various types of advancement introduced in Endodontics.(1) The specialty also includes endodontic implants; bleaching of discoloured teeth, retreatment of previously endodontically treated teeth with special instruments, post-endodontic rehabilitation of teeth with more preservation of tissues and the management of traumatically injured teeth.(2) But unfortunately, endodontics appears to be similar with root canal treatment among the undergraduate students.This reality necessitates dental students to be satisfactorily equipped with knowledge as well as experience in endodontic procedures prior to working independently. (3)The UG students it is necessary for the UG students to understand what should be the extent of endodontic training, so that they will be able to render basic endodontic treatment (4). In this way, it is the duty of dental schools to set up their understudies to attempt at any rate straightforward root trench medicines of unsurprising quality on graduation. [5] In India the undergrad (UG) preparing in endodontics is restricted to conclusion of endodontic sores, straightforward imperative mash treatment and root channel treatment for foremost teeth. The UG understudies and the assistants are thought about fledgling, so it is fundamental that instructors comprehend what ought to be the degree of endodontic preparing that must be conferred to the understudies previously they graduate, with the goal that they will have the capacity to render essential endodontic treatment. This examination planned to assess the fourth year understudies and assistant's observation and state of mind toward learning, in rendering endodontic treatment, picking endodontics as a strength for post-graduation and general supposition of the claim to fame.(6,7)There are numerous references in the dental literature regarding the quality and outcome of endodontic treatments carried out by dental students; however, there is scarce information regarding the way students perceive the branch of endodontology and their level of self-confidence about various aspects of endodontic treatment with respect to their future practice.(8)The aim of

this survey was to gather information about the general opinion of dental students in Saveetha dental college regarding endodontic treatment, to analyze their perception of this significant branch of dentistry and how they self-evaluate their confidence level in endodontic treatment.The aim of the study is to evaluate the dental students' perception and attitude toward learning, in rendering treatment, choosing endodontics as a specialty for post-graduation.

Materials and Methods

A questionnaire study survey consisting of 10 multiple-choice questions was compiled and distributed among 100 undergraduate dental clinical students studying in Saveetha dental college.A pilot study was conducted to check the feasibility and reliability of the questionnaire.The main domains appraised were preclinical and clinical training in endodontics, their opinion and knowledge in endodontics as post-graduate specialty.All answers were kept confidential, and no individual students were identified. The students were not allowed to re-participate in the survey once completed.

Result

Total number of undergraduate students participated in the study were 100. 92% of the students participate think endodontics as one of the major branch in dentistry concerned about esthetics whereas the remaining 8% disagreed to it. The analysis for question no 2 showed 22% of them opted cone beam computed tomography in pulp all disease diagnosis as the best suited advancement in endodontics and 28% felt sonic irrigation for cleaning and shaping as best while 50% of them found optical occurrence of tomography in diagnoses of pulpal disease as the best.Analysis of question no 3 revealed that 78% of the students were not sure of microsurgical endodontics though 18% responded yes. 74% of the students thought microsurgical endodontics created a revolution and 6% gave a negative response while 20% had no idea about microsurgical endodontics means. 44% students suggested that rubber dam isolation is good but time consuming and 40% taught its unnecessary as it may hurt the patientand 16% mentioned it is really important to isolate rubber dam for safety measures. 52% of the students responded that endodontics makes lot of money when opted as post graduation and 12% felt that endodontic can be specialised for the advancements it has seen. And 36% of the students refused to take endodontics as their post graduation. 78% of the students suggested that use of rotary instruments are not thought in an effective manner

and also 4-6% found it not helpful. 64% of the students responded yes that undergraduates just must be trained to treat molar RCT and 34% feel it has high risk of perforations. 88% of the undergraduates suggested that they were confident to identify and refer patients with advanced endodontictreatment.

Discussion

With rapid changes taking place in treatment techniques and materials in the field of endodontics, it is important that UG students are equipped with understanding and preclinical experience while using these instruments and materials before treating patients. There is a wide variation in the way the endodontics is taught and the level of competencies developed in UGs in various institutions across the world.(9,10) It also recommended that endodontic educational aids such as models, 3-D interactive tooth atlas which combines sound, text, stills and video with interactive learning should be used as educational adjuvants. (11)Studies have suggested that endodontic computer simulation programs results in significant gain in knowledge and can successfully replace traditional learning strategies.(12) The undergraduate students are not much convinced that the use of rubber dam is effective and efficient in endodontics were as in other studies they have shown students preferring rubber dam more convenient and effective.(13)

In the USA, it was discovered that a dental undergrad's "possession of special skills or talent”was the principle explanation behind needing to practice as opposed to any money related factor, [14] and once more, Orthodontics was the most favoured subject. This investigation additionally reasoned that sexual orientation was not a vital determinant when it came to picking strength, which is predictable with past examinations [15,16]. In any case, later research [16] did among fourth year dental understudies at another school inside the USA found that sexual orientation had an effect on the decision of claim to fame, and that guys were seven times more inclined to progress into an Oral and Maxillofacial Surgery field, while females were four times more slanted to think about Pediatric Dentistry. This investigation found that 'pleasure in giving consideration' was the major impacting factor for picking any postgraduate instructive heading. Discoveries of the Annual American Dental Education Association [17,18] whose exploration included senior dental understudies from every dental school over the USA likewise announced Orthodontics to have been the most mainstream claim to fame for dental understudies from 1995 to 2004, trailed by Oral and

Maxillofacial Surgery and Pediatric Dentistry. As anyone might expect these three claims to fame were likewise the most usually offered as postgraduate courses by both American and Canadian dental school.[19,20]

A survey by Al-Jewai et al. presumed that PC helped learning is proposed to help conventional learning strategies, yet not to supplant them. [21] Only 53.2% of the respondents trust that they have been prepared in preclinical endodontics utilizing removed teeth models. 71% of the understudies trusted that extraordinary preclinical preparing will assist them with managing patients certainly. Dhima et al. assessed dental understudies recognition on dental fortes and components that can assume an essential part in understudies choice to seek after claim to fame preparing or vocation decisions and inferred that happiness regarding giving consideration in a strength or field was recognized as the absolute most vital factor in picking a claim to fame profession. [22] 84.3% of the members in the review recommended that they would have some expertise in endodontics if given an opportunity, which is a positive sign for the claim to fame.

In contrast to past examinations [23], this present investigation found that sexual orientation had an impact on choice to practice, and essentially, twice the same number of females contrasted with guys was undecided on specialization. This is justifiable as female dental practitioners, notwithstanding working and contemplating, are regularly dedicated to raising youngsters, with, all things considered 71% of female dental specialists announced as having kids [24]. Childcare needs will impact the future work examples of female dental specialists [25]. Also, more female than male dental understudies inside the UK hope to remove additional time from their future professions to focus on childcare [26].

87% of students associated endodontics with root canal therapy. But there is a paradigm shift in management of pulpal and periapical diseases with emphasis on vital pulp therapy, regenerative endodontics, microsurgical procedures, post-endodontic restorations, non-vital bleaching for esthetics, endodontics as a part of interdisciplinary treatment modalities , thus suggesting need to emphasis on these treatment modalities during teaching of this specialty. [27]93% of the students suggested that there should be a change in the teaching methodology. Respondents also recommended that endodontic educational aids such as models, 3-D interactive tooth atlas which combines sound, text, stills and video with interactive learning

should be used as educational adjuvants. Studies have suggested that endodontic computer simulation programs results in significant gain in knowledge and can successfully replace traditional learning strategies. [28],[29] According to Urbankova, eight hours of computerized dental simulator training conducted early in the preclinical operative dentistry improved student performance which could also be true for endodontic preclinical training. [30]

Flare-ups are unfortunate circumstances that may emerge over the span of endodontic treatment, requiring an unscheduled visit in some cases.[31] It is additionally obvious that, flare-ups don't specifically impact the result of the endodontic methodology, yet are fairly distressful circumstances coming about because of the disturbance of the harmony between the host safeguard component and chafing operators.[31] One reason for the event of between arrangement flare-ups might be procedural mistakes amid the execution of endodontic treatment, for example, expulsion of intracanal content incidentally into the periradicular tissues. It can be guessed that flare-ups might be experienced all the more oftentimes in the understudies facility, conceivably because of inability of understudies enabling them to make some procedural blunders, for example, overinstrumentation or expulsion of irrigants and intracanal flotsam and jetsam.

Conclusion

This study concluded that most of the undergraduate students are interested in persuading endodontics as a specialty for post-graduation. Thus it needs more emphasis on preclinical endodontic training and clinical training for management of all pulpal and periapical lesions with different modalities at the undergraduate level. This study shows that a large number of undergraduates had an intention to specialise, with Restorative Dentistry and Orthodontics being the most popular intended subjects, although many were still undecided at this stage.Endodontics is a vibrant, evolving and interesting clinical specialty. Intense endodontic training at UG level prepares the graduates to provide good basic patient care in clinical practice studies comprising other dental schools will be helpful in precisely determining the extent of instillation of adequate skills in endodontology and major missing areas that need further improvement.

Abstract

Background: Motivating patients to seek orthodontic treatment affect adherence to treatment suggestions, treatment outcomes, and patient satisfaction. Prejudiced notions about treatment and various fears have created a resistance or hesitation towards orthodontic treatment in women. The aim of this study is to assess the mind set and overall attitude of female adolescent patients towards orthodontic correction of malocclusion.

Materials and methods: A questionnaire was prepared and distributed to 50 female adolescent patients with malocclusions visiting Saveetha Dental College and Hospital. All questionnaires were anonymously collected and the data was kept confidential and not used for anything apart from the study purpose.

Results: It was seen that the female adolescent patients were unwilling for braces as they were scared or that they found it embarrassing, expensive, painful and has long treatment duration.

Conclusion: The attitude of female adolescent patients with malocclusions for orthodontic treatment is studied so as to be able to convince them for orthodontic treatment.

Keywords*: Attitude, Females, Orthodontics*

Introduction

Orthodontic treatment is the process of aligning the teeth or correcting other irregularities, which thus improves health, function, appearance, and social well-being [1,2].Malocclusion is an occlusion where there is a mal-relationship between both the arches in either of the planes or there are irregularities in tooth position which extend beyond the normal limits. The etiology of malocclusion can be genetic or environmental and or a combination of both along with various local factors such as oral habits, tooth anomalies etc. Malocclusion for the most part makes sentiment disgrace for their facial appearance and may likewise give sentiment bashful in their society. The results of the orthodontic treatment are anticipation of tissue destruction, change in physical capacity and appearance. The malocclusion is seen to affect oral health by causing increase in the incidence of caries and also temporo-mandibular disorders. The many benefits provided by orthodontic treatment include, the prevention of damage to the tissues, improvement in aesthetics and functioning of the teeth. The readiness to pursue orthodontic treatment is influenced by various factors such as the desire to look good, improving self-esteem and improving his or her self -perception of dental appearance [3]. Females are generally more concerned about the esthetics of their teeth. There is a lack of research on the motivation of adults seeking orthodontic treatment, [4]especially in women. Both positive and negative motivations are correlated with adherence [5] treatment.Unacceptable dental appearance has been found to exert a negative impact on self-image, career advancement, and peer-group acceptance. This in turn will have an adverse influence on an individual's level of social interactions. Such esthetic concerns and adverse influence on psychosocial well-being are the primary factors for decision to start orthodontic treatment [6].Changes in morphogenesis and physiology of dentofacial structure over time and an increased concern for dental appearance and orthodontic treatment with age have become apparent rather than inadequate decisions and a provision of care during childhood and adolescence [7]. Orthodontists traditionally have considered oral health and function as the principal goals of treatment. However, recently, there has been growing acceptance of esthetics and its psychosocial impact as an important treatment benefit [8].The benefits of orthodontic treatment are prevention of tissue damage, improvement in esthetics, and physical function[9]. In orthodontic clinical practice, as well as in otherdental specialties, treatment success does not depend solely on factors such as proper diagnosis, biocompatibility, and skill of the dentist but also depends on the patient’s cooperation [10].A

compliant orthodontic patient may be described as a patient who practices good oral hygiene, follows appropriate diet, maintains appliance without breaking, keeps regular appointments, and follows instructions of the doctor. The cooperation of the patient helps in achieving treatment goal more expeditiously. The compliant patient may be identified by personal and demographic characteristics such as; age, sex, personality type, social class etc. Since sex is an imperative attribute variable, it is frequently reported in many studies [11].If the patient is not cooperative and does not follow the instructions given by the dentist may lead to unsatisfactory outcomes of the treatment [12,13]. Adolescence is the phase where orthodontic treatment is most recommended. It is also is a period in which importantphysical, social, and emotional changes appear [14]. The cooperation of the adolescent patients can be altered based on extrinsic factors (social stereotypes,gender, educational level, family) and the intrinsicfactors (personality, temperament) [15,16]. A clinician must precisely know and explain to patient how much time is needed for such adaptation to occur. Due to insufficient information on the treatment and lack of communication between the orthodontist and the patient, treatment was discontinued by the patient in many instances.Assessment of patients' expectations is central to understanding oral health needs, patient satisfaction with treatment, and ultimately the perceived overall quality of health systems. Mismatch between patient desires and the service received is related to decreased satisfaction. The overall aim of orthodontic care should be good treatment results and satisfied patients but at a reasonable cost. To reach this goal it is important that the quality of care is continuously and systematically evaluated and documented by means of professional clinical assessments and patient questionnaires or interviews. Patients with inappropriately high expectations may be dissatisfied with the optimal care and those with inappropriately low expectations may be satisfied with deficient care.Orthodontic treatment is highly technique-sensitive and timeconsuming clinical procedure. Patient's understanding in its technical aspect and compliance in appliance maintenance are important for management and successful outcome of the treatment [17]. The unwillingness of female adolescent patients with malocclusions for orthodontic treatment is studied so as to be able to educate them on the long term effects of malocclusion. Hence being able to convince them for opting to go with the orthodontic treatment.

Materials and Methods

A questionnaire based study was conducted at Chennai to determine the attitude of female adolescent patients towards orthodontic treatment. Data was collected using a structured, self-administered questionnaire which was designed after reviewing recent articles, developments and also similar questionnaires that are based on the objectives of the study. The questionnaire was divided into three parts. The first part included questions based on demographic data, the second part consisted of questions related to their knowledge on malocclusions and the final part consisted of an open question asking them to state out their reason for not undergoing orthodontic treatment. The questionnaire was distributed to 50 female adolescent patients with malocclusions. All questionnaires were anonymously collected and the data was kept confidential and not used for anything apart from the study purpose.

Results

From the survey, it was found that 54% of the adolescent females stated that malocclusion is the irregular positioning of teeth, 24% of the females thought malocclusion to be a state where there are missing teeth and 22% thought it to be a condition having broken teeth (Figure.1). 48% stated thumb sucking to be the etiology of malocclusion, 24% suggested accidents, and 22% said improper brushing habit to be the cause and 6% suggested sticky food to be the etiology (Figure.2). 46% of them stated that decayed teeth are not an outcome of malocclusion. Similarly, 28% suggested discoloured teeth are not an outcome, 20% said that food accumulation is not an outcome and 6% stated that compromised aesthetics is not an outcome of malocclusion (Figure.3). When asked on how one could correct malocclusion, 54% suggested braces, 18% suggested removing the tooth and 4% suggested surgery (Figure.4). Only 48% of them were aware that they had a malocclusion whereas, the remaining 52% were not aware (Figure.5). On asked as to why they were not correcting the malocclusion, 40% stated that it was embarrassing to wear braces, 18% stated that the treatment was too expensive, 12% stated that the treatment was that of a long duration, 8% had no interest to do the treatment, 8% stated it would painful, another 8% had concerns that food would get stuck to the braces, 4% were scared to undergo treatment and 2% stated that they received no complaints on how they looked (Figure.6).

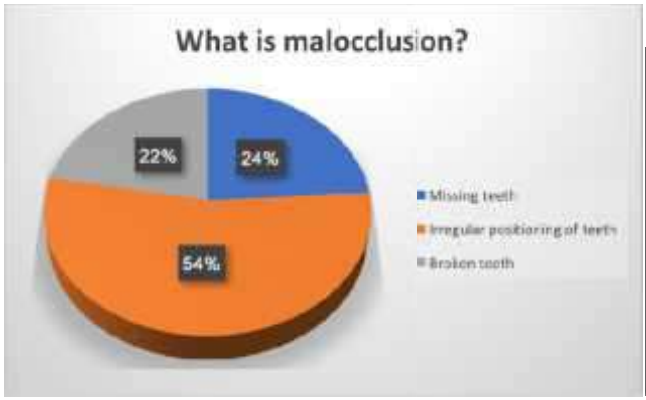

Figure.1 – The response given by the patients when asked what they knew about the term malocclusion.

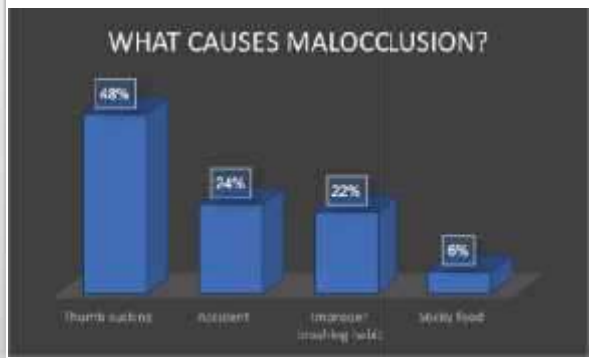

Figure.2 – Their response when asked about the etiology of malocclusion.

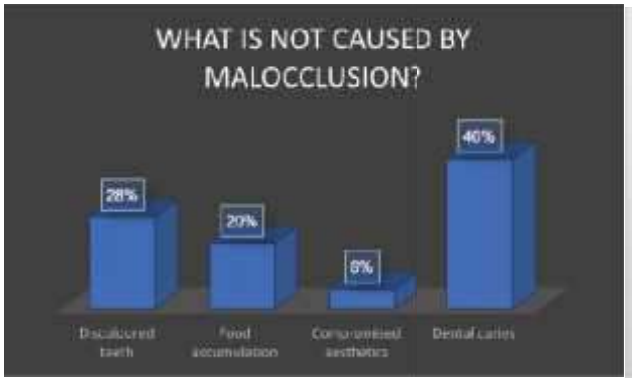

Figure.3 – Their response when asked what were not outcomes of malocclusion.

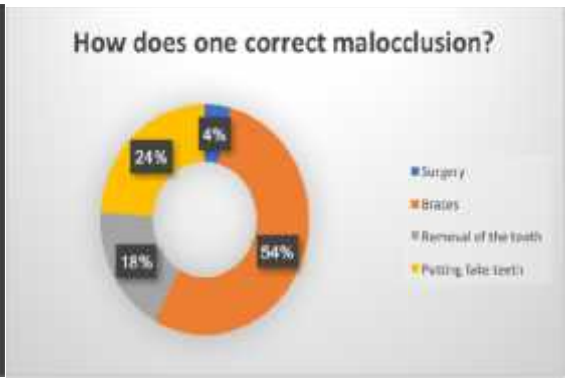

Figure.4 – Their response when asked on the methods of management of malocclusion

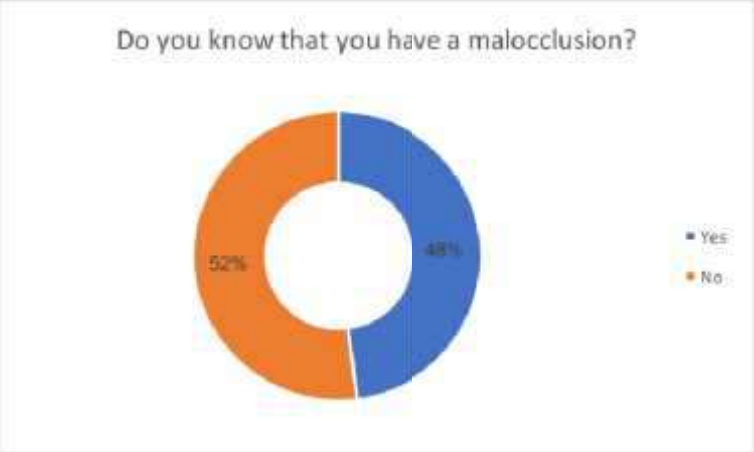

Figure.5- Their response when asked if they were aware of their malocclusions.

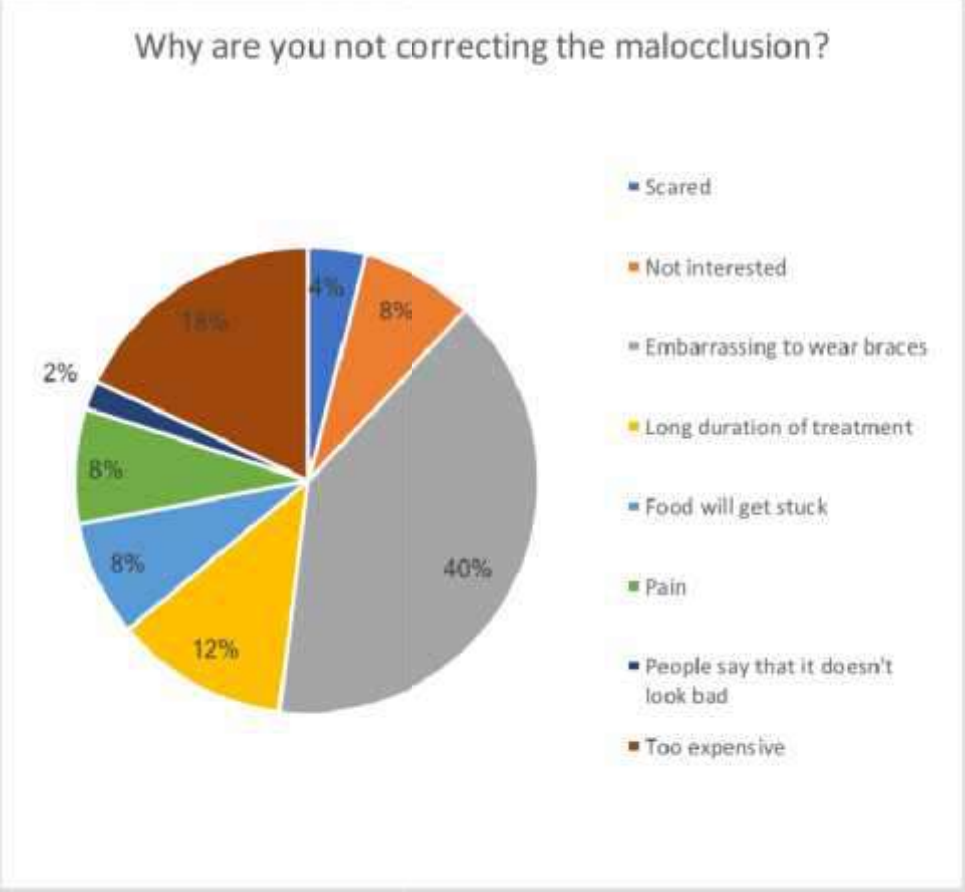

Figure.6 – Their response when asked for the reasons for not correcting their malocclusion.

Discussion

Many factors such as age, gender, opinion of dental appearance, socioeconomic status and educational status can influence the patients desire to undergo orthodontic treatment. However, it all depends on how the patients perceive orthodontics. Perception is defined as the way in which something is regarded, understood, or interpreted. In orthodontics, perception deals with the way this field of dentistry is seen by the people. Some consider the correction of malocclusion a necessity to achieve proper esthetics while few consider it as an unimportant health condition and few are concerned with problems regarding difficulty in speech, mastication, etc. In this age and era, where aesthetics play a significant role in each and every walk of life, be it at a personal or professional level, there has appears to be a massive surge in the demand for orthodontic services. Egolf et al [18] studied factorsassociated with compliance. These factors were considered as a combination of personality type, negative motives and positive motives. The present study assessed the reason for the patients not going forward with orthodontic treatment. The assessment on attitude of the patient was related to perception on treatment service, cost and also personal factors such as embarrassment. However, many orthodontists have difficulty to deal with behavioral compliance of their patients. Thus, orthodontists seem to deal with the complex issue of motivating and improving the compliance of their patients during the appointments. These involve educating the patients and/or parents about the importance of compliance. Moreover, the orthodontists need to verbally praise for compliant behavior. Treating the patients with respect, establishing a good communication, and informing the patients about the progress of treatment offered to them are rewarded as well. However, an orthodontic patient differ psychologically from each other in the perception of the way their practicing orthodontist contacts and communicates with them. Understanding the behaviors and attitudes of the patient can provide valuable information for the orthodontist prior to developing treatment plan and orthodontic treatment[19]. The study on pain experience during orthodontic treatment among Nepalese patients was analyzed by Kafle and Rajbhandari [20].Attitudes and perceptions towards dental appearance differ among populations and among individuals [21]. Various studies identified female orthodontic patients as more cooperative than males [4,5,10]. The present study showed similar finding in many parameters that female Nepalese patients possessed better understanding and perceptions towards ongoing orthodontic treatment. Siddegowda and

Rani [22] found a decent amount of knowledgeabout orthodontist and mal-positioned teeth, and relatively less awareness about the varieties of orthodontic treatment among children in Indian schools by means of an epidemiological survey. The orthodontic patients were educated on oral hygiene, food restriction, and regularity of appointments. Anorthodontist's interpersonal behavior and role in patient motivation is another aspect of successful orthodontic treatment. The orthodontist should give positive feedback and communicate with the patient on the issues of patient cooperation and their inconveniences. Orthodontists should explain about the appliance including retainers, and advice on oral hygiene, dietary control and appliance maintenance methods [23].A successful orthodontic treatment is largely dependent on the knowledge and skills of the clinician and the cooperation of patients and also that of the parents, in case of children and adolescent patients. Major considerations regarding patient cooperation are regularity in keeping appointments, compliance in wearing elastics, headgear or wearing removable appliances, refraining from chewing hard and tenacious substances that are likely to distort the arch wires, and remove bonded brackets and maintenance of oral hygiene. Laxity in following these instructions may lead not only to compromised treatment but also to slow progress of treatment, loss of chair time, increased number of visits to the orthodontist and frustration for the clinician, patient, and parents [24]. Personality traits, pain perception and attitude of the patient toward orthodontic treatment can be important factors influencing cooperation of the patient and knowledge of their interrelationship will help to gain maximum cooperation from the patient and thereby optimal treatment results.Patients' main reason for seeking orthodontic treatment is to correct dento-facial disharmony. But males have different expectations of orthodontic treatment than females. Males focus more on social well-being while females concentrate more on their improved appearance.Discomfort and pain are common during orthodontic treatment. Approximately, 90% to 95% of orthodontic patients are reported to experience pain during the course of orthodontic treatment. In orthodontics, the main cause of pain is the application of forces to induce tooth movement. Pain is also influenced by motivation, gender, and personality factors. Pain and discomfort can be one of the important discouraging factors for orthodontic treatment[25]. It is very important to understand the personality of the patient, pain perception, and attitude toward treatment so as to customize the treatment protocol to achieve optimum patient compliance and patient satisfaction. Pretreatment assessment of personality is one of the important factor for achieving patients' compliance, even though due

emphasis has not been given in the literature to personality assessment before, during and after orthodontic treatment. Objective criteria are lacking for delineation of personality, the available instruments are complex and orthodontists are not familiar with them[26]. About half the number of patient thinks that wearing the braces do not look good. About two third of the patients think that orthodontic treatment is expensive. In general, the attitude of female adolescent patients towards orthodontic treatment is moderate. It is important for practicing orthodontists to inform patients about the retainers, appliance maintenance and build inter-personal rapport with the patients. The importance of patients' perceptions regarding orthodontic treatment cannot be underestimated as it is the patients who receive treatment and need to gain satisfaction from improved esthetics andfunction.It had been hypothesized that increased experience with and availability of orthodontic service should be translated into differences in esthetics rating and perception of treatment need.The decision making process that a person undertakes when judging his/her own dental esthetic satisfaction may be broken down into several steps. First to know about the awareness about their own dentition, after this step, second their self-satisfaction, and finally their attitude toward orthodontic treatment. We may postulate that females had very good knowledge about dental esthetics compared to the males. The subjects who had malocclusion and did not report to the orthodontic clinic seems to believe that teeth do not affect their esthetic value and this appeared to be more of an ignorance that teeth does significantly affect facial appearance and lack of knowledge was the main factor that kept away from treatment[27].Regarding self-satisfaction about their teeth, the study indicates that the subjects did make fairly accurate self-evaluation of their own malocclusions. The unsatisfied subjects with their dental esthetics had a positive attitude toward orthodontic treatment. The satisfied subjects with their dental esthetics were aware of the attractiveness of their teeth[28].The practitioners shall improve the patient attitude by shortening the waiting time of patients at waiting room, adequately spend time on procedure and charge the treatment cost more reasonably.

Conclusion

The unwillingness of female adolescent patients with malocclusions for orthodontic treatment is studied so as to be able to educate them on the long term effects of malocclusion. Hence being

able to convince them for opting to go with the orthodontic treatment. Majority of the adolescent females were not aware that they had a malocclusion. Those who were aware did not want it because of the embarrassment it would cause and also because they found it very expensive. By teaching them about the merits and demerits of the treatment, one can positively motivate the patient to undergo orthodontic treatment.

Abstract

Introduction: Oral health awareness has an important role in the general health and well being of the individual. As dental students, we have an enormous role to play in maintaining the public health .Hence it is very important to have a sound knowledge and importance of Oral hygiene measures and their importance.The aim of this study was to know the views of dental students towards their oral health and over all public oral health development.

Materials and Method: A pretested structured questionnaire was used to assess the attitude of dental students towards their oral health. The awareness about their oral health, self-evaluation and their oral hygiene practices were assessed.A sample of 100 students was evaluated and their response was recorded , tabulated and analyzed.

Results:The frequency of the dental student's brushing interval and duration has been highlighted through the study that a Majority(58 percent) of the students brush twice a day, the rest brush either only morning(39 percent) or only night(3 percent). The brushing duration has an equal proportion(50 percent). About 69 percent of the students showed concern about having bleeding gums and about 75 percent of them do a self appraisal of their teeth.

Conclusion: From the study done we can conclude that the dental students were very much concerned about the damages that were caused on their oral cavity. They were also aware of the need to maintain a proper oral hygiene and the methods to be followed for the same. A positive outcome about the knowledge of the students have been concluded from the study

Key Words:*attitude, dental students, questionnaire, oral hygiene, awareness*

Introduction

Health is a universal human need for all cultural groups. General health cannot be attained or maintained without oral health. The mouth is regarded as the mirror of the body and the gateway to good health. [1] Oral health education begins from footsteps of awareness. Today, various dental health education programs have been conducted in schools and other settings; however, these efforts will not succeed until people are not aware of the importance of oral health and positive attitude toward treatment modalities.

Oral hygiene is the method by which the tooth and its surrounding structures are clean in order to prevent any disease. The factors that influence the oral hygiene are generally the life style, culture,foodhabits,location[1]. In the upcoming generations the need for a good oral hygiene is felt and hence the dental health professionals are insisted to take adequate measures to decrease the risk of oral diseases[2,3]. Since the dental students have exposure to the dentistry world, conducting a survey would help in finding out the their attitude towards developing a better oral hygiene for themselves as well as the community. Hence, a cross sectional study was conducted to evaluate the knowledge on oral health and practices of the dental students.

Material and Method

A pre-tested structured questionnaire were given to 100 students of Saveetha Dental College and Hospitals, Chennai who were undergoing the undergraduate programme. The feedback of the students regarding the questionnaire were gathered and the data collected were entered for further evaluation. Evaluation of the data was done and the output was obtained.

Results

A cross sectional study was conducted among 100 dental students to evaluate their knowledge on oral health and practices.

From the questionnaire it is portrait that a large proportion(73 percent) of students think that it is very required to visit the dentist followed by a proportion(22 percent) of students who think it is required at times and 5 percent even think it not required.

Table 2 reveals that the reasons for the visit being regular check ups tops the list with 54 percent followed by the reason of pain occurrence with 34 percent, then comes the reason of parental force with 7 percent and the last reason of never visiting has 5 percent.

Table 3 illustrates the Self evaluation of the dental students. About 69 percent of the students show their concern of having bleeding gums, where as 31 percent of them are not concerned about having bleeding gums.

It is clear that a majority(75 percent) of students worry about discolouration of the teeth and the rest(25percent) are not worried.
About 75 percent of the students look at the mirror and do a self appraisal of their teeth and 25 percent of them do not do.

Table 4 demonstrates the various Oral hygiene practices followed by a dental student. Roughly 78 percentage of the dental students feel that they use the correct brushing technique while brushing and the rest 22 percentage of them feel they are not using the correct technique.It is shown that about 63 percentage of the students use proper toothbrush and paste.The usage of floss and mouth wash is limited to 28 percentage and 72 percentage does not use them on a regular basis.

78 percent of the students do a regular tongue cleaning where as the rest 22 percent fail to do so. The frequency of rinsing the mouth after meal is 73 percent and the rest 27 percent lack it.

The frequency of the dental student's brushing interval and duration has been highlighted through the study that a Majority(58 percent) of the students brush twice a day, the rest brush either only morning(39 percent) or only night(3 percent). The brushing duration has an equal proportion(50 percent).

Table 5 explains the Awareness of the dental students on the various aspects of the dental health. The implication of data from the above table is that 76 percent of the students are aware of the terminology of the sticky deposits

Graph 2 illustrates the frequency of the student's reason for preserving the tooth. About three fourths of thee study participants want to preserve their tooth for aesthetic appearance, 16 percent of them want to preserve it for masticatory purpose and the rest 12 percent preserve it in order to avoid false teeth.

Table 1: Visiting dentist.

		Percent
	Often	32.0
	Rare	68.0

Table 2: Reasons for visiting dentist

		Percent
	Regular check ups	54.0
	Parental force	7.0
	When pain occurs	34.0
	Never	5.0

Table 3:Distribution of study participants based on Self Evaluation of their oral hygiene

QUESTIONS\ RESPONSE	YES [IN PERCENTAGE]	NO [IN PERCENTAGE]
Worry about bleeding gums	69	31
Worry about coloured teeth	75	25
Worry about bad breathe	79	21
Self appraisal of teeth	75	25
Concerned about bad oral hygiene	80	20
Concerned about sticky deposits	70	30

Table4:Distribution of study participants based on Oral HygienePractises

QUESTIONS\ RESPONSE	YES [IN PERCENTAGE]	NO [IN PERCENTAGE]
Using correct brushing technique	78	22
Using toothbrush and paste	63	37
Using floss and mouth wash	28	72
Regular tongue cleaning	72	28
Rinse your mouth after meal	73	27

Table 5:Distribution of study participants based on Awareness on Oral Hygiene Practices

QUESTIONS\ RESPONSE	YES [IN PERCENTAGE]	NO [IN PERCENTAGE]
Terminology of sticky deposits	76	24
Consumption of Soft drinks and carbohydrates affects	50	50
Damage tooth structure due to prolonged brushing	83	17
Awareness of procedures done	81	19
Regular follow ups with dentist	63	37
Preaching about oral hygiene to others	87	13

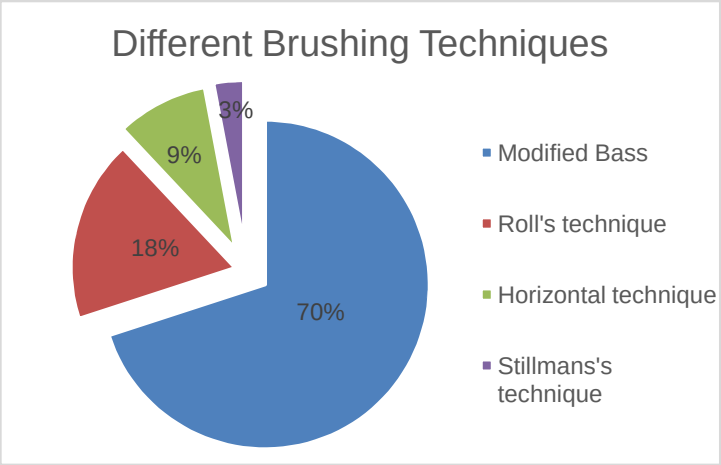
Table 6: Problems of improper oral hygiene

		Percent
	Dental caries	74.0
	Periodontal disease	13.0
	Unaesthetic appearance	9.0
	Malocclusions	4.0

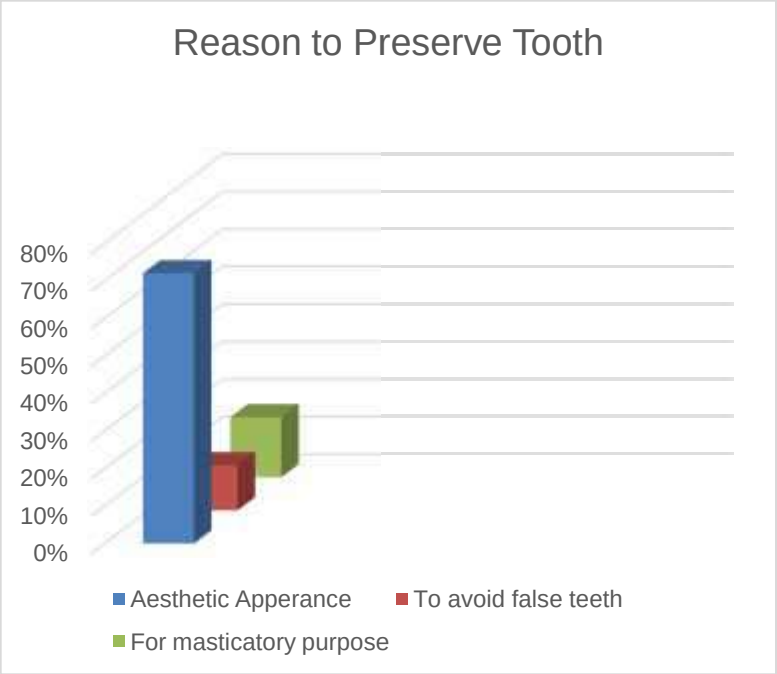
Table 7:Frequency in Changing in toothbrush

		Percent
	1-3 months	70.0
	>3 months	13.0
	When bristles wear out	15.0
	Never	2.0

Graph 1: Different brushing techniques used by the study participants



Graph 2: Reasons for preserving tooth



Discussion

From the study done, the dental students are very much concerned about the damages that are caused on the oral cavity like bleeding gums, discolouration of the teeth, presence of sticky deposits, intake of soft drinks and carbohydrates and tooth structure damage due to prolonged brushing. Evaluation of their understanding helps in knowing their self awareness and also their interest in taking care of themselves before preaching it to others.

Nearly three fourths of the study participants rarely visit the dentist and only a minority of them visit regularly thus explaining the fact that a majority of them are aware of the precautionary measures to preserve their teeth and avoid visiting the dentist.

More than half of the study participants were concerned about bleeding gums which infer that the dental students were aware of the various problems that can cause bleeding gums and are concerned about gum care.

Majority of the students did self appraisal of the teeth, which leads to a conclusion that the majority of the students are aware of the need to maintain a good oral health.We can also infer that the dental students follow the correct duration while brushing while varience is accepted and the brushing twice is also followed meticulously by them.[15]

Majorityof the students are really concerned about having a bad oral hygiene and show their concern towards this sticky deposit .Thus implying that being a dental student the concern for maintaining a good oral health and their awareness about the various problems caused due to having a bad oral hygiene is of utmost concern.

The usage of dental floss and mouth wash was limited to nearly one fourth of the students which is similar to that of a study conducted by FahmidabintiAbd Rahman et al.[9,16] From the above findings the usage of toothbrush and paste is prevalent among the dental students as it acts as mechanical and chemical removal of deposits on the oral cavity respectively.[17,18] But the need for the awareness of the usage of floss and mouth wash is felt here.

Most of the students rinsed their mouth after a meal which was on contradictory to a study by Sandhya et al where most of the study group didn't rinse their mouth after a meal.[7] This helps us arrive at a conclusion that the importance of mouth rinsing after meal is known to the students in order to keep their oral cavity free of remnants of food particles.[20]

The modified bass technique was used by a majority of the students, and hence it implies that most of the were aware of the correct brushing technique.

Being dental students they are aware of the different terminologies used in dentistry which is very essential for communicatory purpose with the fellow dentists. The frequency of students who are concerned about the intake of soft drink and carbohydrates and those who are not concerned are equalwhere in a study by Gopinath et al revels 59.4 percent of the population where concerned about the carbohydrate and sugar coated food items.[8] Weinferred from the study that the dental students are aware of the problems caused due to the consumption of soft and carbohydrates and try to avoid it but still their desires does not allow them to stay completely away from it.

A majority of the studentsbeing dentist thought that prolonged brushing damages the tooth structure, as the bristles can erode the tooth surface when used along with chemicals(tooth paste). The awareness of the dental students to the dental procedures done to them by their dentist is 81 percent similar to that of Jembulingamet al.[6] As a dental students they are

more keen on knowing the different procedures done to them and the significance of each of it.

majority of the study pollutants go for regular follow ups and that the knowledge about the need to go to the dentist for regular follow up is felt by the dental students.[13,14] The portrayal of the frequency of the students who preach about maintaining oral hygiene was also observed. Majority of the dental students preach about maintain a good oral hygiene. As a dental student they know the advantages and disadvantages of having a oral hygiene and hence we can infer that most of them preach it for the welfare of others. [11]

Knowledge about the various problems caused by improper oral hygiene is known to the dental students and the dental caries formation is the main concern of it. As a majority of the study participants think that dental caries arise due to improper oral hygiene where as the periodontal disease, unaesthetic appearance and malocclusions are few other problems caused due to improper oral hygiene.[19]

Majority(70 percent) of the students change their tooth brush every 1-3 months, where as in a similar study by Pradeep Kumar et al only 40% of the population changed their brush every 1-3 months. [10] This helps us infer that changing the toothbrush is necessary and the students are aware of it.

We can infer from the study that the students prefer aesthetic appearance over any other reason for preserving the tooth. [12,19]

Conclusion

Dental's students have widespread knowledge about the damages caused to the oral tissues due to etiopathological contributing factors like sticky food, soft drinks intake and carbohydrate and tooth structure damage due to prolonged brushing Since they have a vast knowledge about the various aspects of dentistry they were able to maintain a good oral hygiene by brushing twice a day for a duration of 1-2min with toothbrush and paste using he correct brushing technique- modified bass technique. Rinsing the mouth after meal, changing the tooth brush regularly and tongue cleaning also added up for the maintenance of a good oral hygiene along with the prevention of bad breath. This reduced their visit to dentist significantly. It is also portraited that an improper oral hygiene results in dental caries, and

hence the visiting the dentist for regular check ups is required in order to preserve their tooth for aesthetic appearance and masticatory purposes. Being a dental student the urge to know the procedures done and to go for regular follow ups during treatment plans can makes the communication between the dentist and the patients easier as there will be a easy understanding of the terminologies used by the dentist. By doing all this a dental student was also able to preach about oral hygiene to others. Thus the attitude of dental students helps in proper orientation of their oral hygiene.

Attitude of Pedodontists towards Pedodontic Speciality Education: A Survey

Boopana .K[1], Magesh Ramakrishnan[2], Geo Mani[3]

Graduate Student[1], Senior Lecturer[2], Department of Pedodontics,
Senior Lecturer[3], Department of Pedodontics

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: To study the attitude of pedodontist with regards to specialty education. The main objective was to correlate the attitude of pedodontists towards their specialty education. Pedodontic specialty education programs are based on university certificate and the hospital certificate.

Materials and Methods: This method of study is a questionnaire with the 5 bipolar descriptive used to indicate degree of satisfaction perceived towards inquiry areas developed from guidelines for specialty education. The major topics covered was patient education, behavior management, restorative dentistry, pulp therapy , interceptive orthodontics.

Result: The purpose of this study was to establish a database analysis of pedodontists attitude towards specialty education.

Conclusion: The survey indicated positive satisfaction levels in relation to behavior management, restorative dentistry, pulp therapy, traumatic injury and interceptive orthodontics, reduced satisfaction levels in the areas of prevention/patient education and child sedation, and significantly lower satisfaction levels for pedodontists in treatment of the special child, hospital dentistry, and conducting experimental and clinical research.

***Key Words**: Pedodontist, specialty education, Attitude, dentists, aids*

Introduction

The pedodontic specialty education programs are based on the university certificate and the hospital certificate. A basic curriculum and instruction level broadly representative of the specialty is required in each setting [1,2]. In a 1996 survey by Bentle and his coworkers, pedodontists indicated " to little" instruction during their training in orthodontics, dentistry for the handicapped , general anesthesia , premedication , research experience , treatment planning and patient education. The study concentrated on conceptions of an ideal gradual program and provided no comparisons between the program settings. The purpose of this study was to establish a data based analysis of the pedodontists attitude towards the speciality eduction and to determine how these perceptions differ by program setting [4].

Data based attitudinal surveys provide quantitative and qualitative information of performance by the determination of correlation magnitudes between variables [5]. Attitudinal surveys account for a substantial portion of education research, and have been frequently used in dental education[6,7,8]. While not useful as as direct measure of use and effect, the data can be used as a comparative basis for self-analysis and future planning[9,10,11]. The Aim of this survey is to understand the attitude of Pedodontists towards the speciality education.

Materials and Methods

A questionnaire was given to 35 pedodontists across various universities in chennai like the Saveetha Dental College and hospitals, Sri Venkateshwara Dental College and hospitals, Sri Ramachandra Dental College and hospitals, Chettinadu Dental College and hospitals, Priyadharshini Dental College and hospitals. A 5- point Liker-type attitude scale with bipolar descriptive was sued to indicate the degree of satisfaction perceived towards inquiry areas developed from guidelines for the specialty education. The major topic areas were prevention/patient education, behavior management, restorative dentistry, pulp therapy, traumatic injury, interceptive orthodontics, dentistry for the special child, sedation, hospital dentistry, and academic dentistry. The MS EXCEL was used for the statistical analysis of the data and it is represented as a bar graph.

The questionnaire that was distributed to the pedodontists is

Note: For each of the following statements, the respondent indicated the degree of satisfaction felt towards his experiences during pedodontic practice.

Key: highly satisfied -5

Mildly satisfied -4

Neutral - 3

Mildly dissatisfied – 2

Highly dissatisfied – 1

Name/Optional

1. Years of experience –
2. The ability to educate and counsel the child and parent to accept and maintain optimum oral health care through.
   a) Use of audiovisual aids
   b) Treatment plan presentation
   c) Rationale of plaque control
   d) Design of preventive program
   e) Fluoride supplementation
3. The ability to guide the behavior of the child to accept oral health care utilizing the following skils or knowledge.
   a) Voice control
   b) Hand over mouth exercise
   c) Restraints
   d) Positive reinforcement
   e) Basic child psychology
4. Mastery of restorative procedures required during the growth period from birth to adolescence.
   a) Stainless steel crowns

b) Polycarbonate crowns
c) classII alloys on deciduous teeth

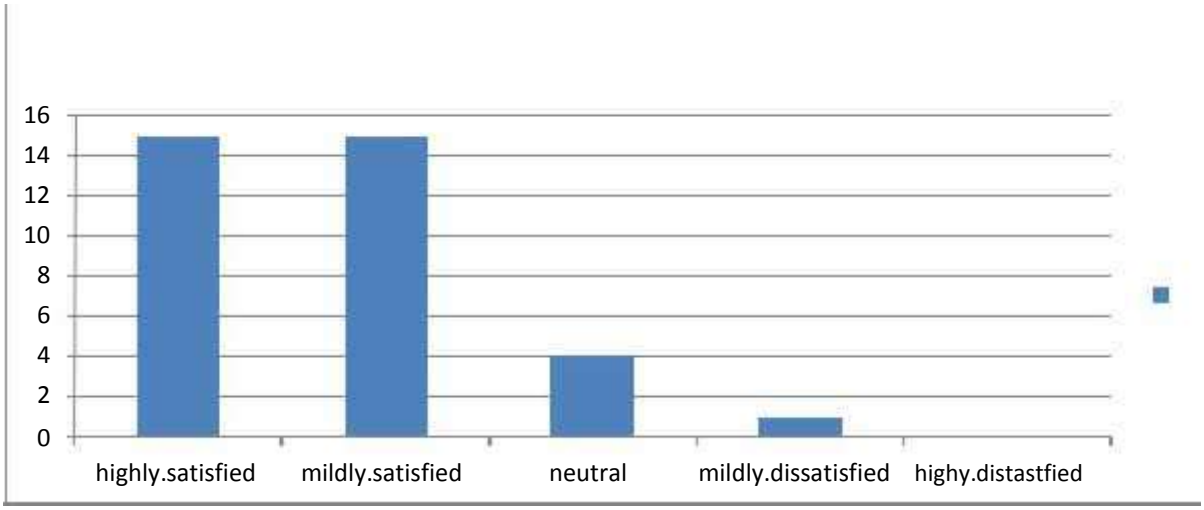
5. Ability to diagnose and treat developing occlusion utilizing interceptive procedures until final development of permanent dentition :
   a) Removable appliance
   b) Techniques of guidance of eruption
   c) Cephalometric analysis
   d) Correction of ectopic eruptions
   e) Minor tooth movement with the fixed appliance
   f) Cross bite diagnosis and correction
6. Knowledge and ability to render competent oral care for the special child with pediatric or medical considerations.
   a) Diagnosis and treatment of herpetic and aphthous ulcerations
   b) Precautions in positive cardio vascular history
   c) Hemophilia – dental approach treatment
   d) Epilepsy and dental treatment
   e) Mentally retarded patients.
7. Knowledge and competency in the utilization of pharmacologic methods of patient management in pediatric dentistry
   a) Oral sedation
   b) Biomedical aspects of narcotics
   c) Intramuscular sedation techniques
   d) Emergency drugs and techniques
   e) Intravenous sedation techniques
8. Ability and knowledge in hospital oral health care:
   a) Biomedical aspects of general anesthetics
   b) Knowledge of hospital protocol
   c) Experience in administering general anesthesia
   d) Operating room experience as dental operator
9. Knowledge and experience in academic pedodontics
   a) Ability to evaluate literature.

b) Teaching experience in didactic and clinical environment
c) Developing and conducting experimental and or clinical research
d) Working knowledge of basic pedodontic literature.

Results

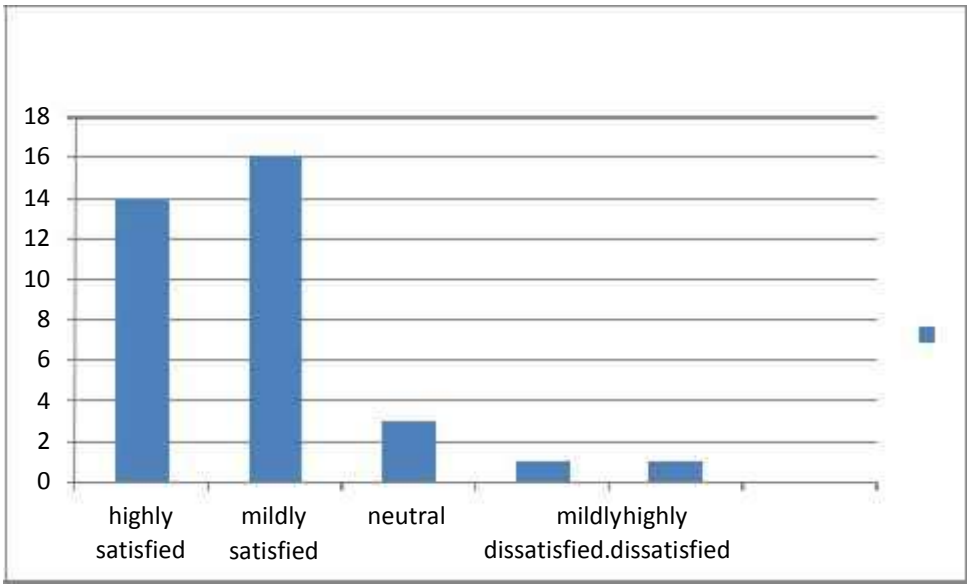
All the questions in the questionnaire were answered by the pedodontists. 86.96% of the pedodontists showed positive results towards the specialty education. The data collected is represented as a bar graph.

Table 1: Ability to educate and counsel the child and parent to accept and maintain optimum oral health care through:



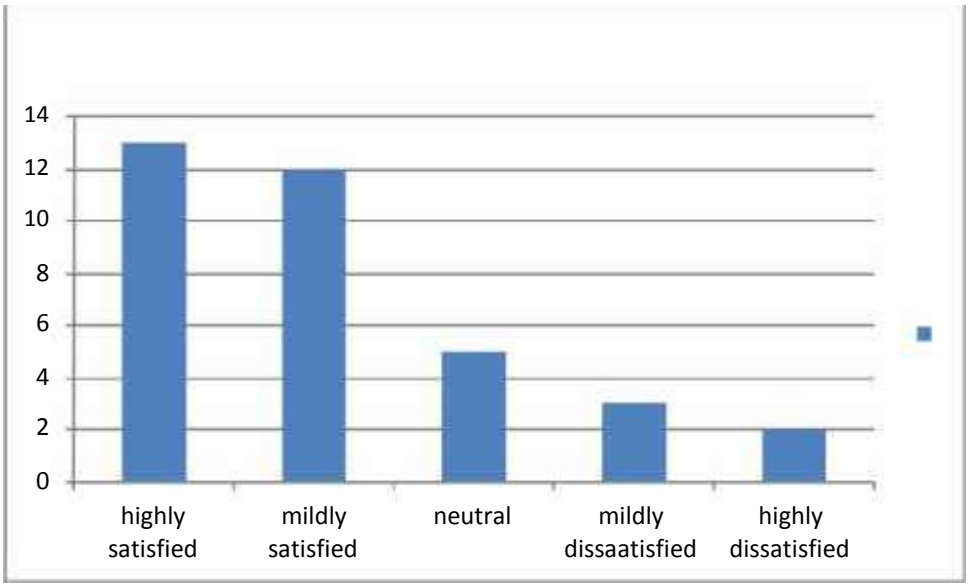
84-86% of the pedodontists were highly and mildly satisfied with the use of audiovisual aids, treatment plan presentation, rationale of plaque control, fluoride supplementation. While 22-24% of the pedodontists showed neutral response to the question and 2-4% of the pedodontists were mildly dissatisfied.

Table 2: Ability to guide behavior of the child to accept oral health care utilizing the following skills or knowledge:



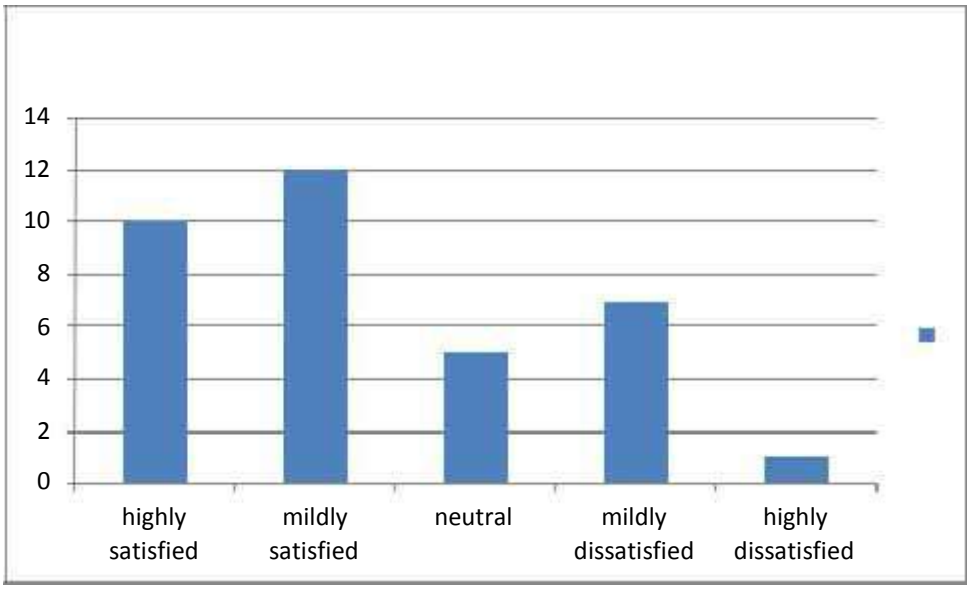
83-85% of the pedodontists showed highly satisfied and mildly satisfied response for the techniques like voice control, hand over mouth exercise, restraints, positive reinforcement, and basic child psychology. 11-15% of the pedodontists were neutral to these techniques and about 8-9% of the pedontists showed mildly and highly dissatisfied response to it.

Table 3: Mastery of the restorative procedures required during the growth period from the birth to the adolescence:



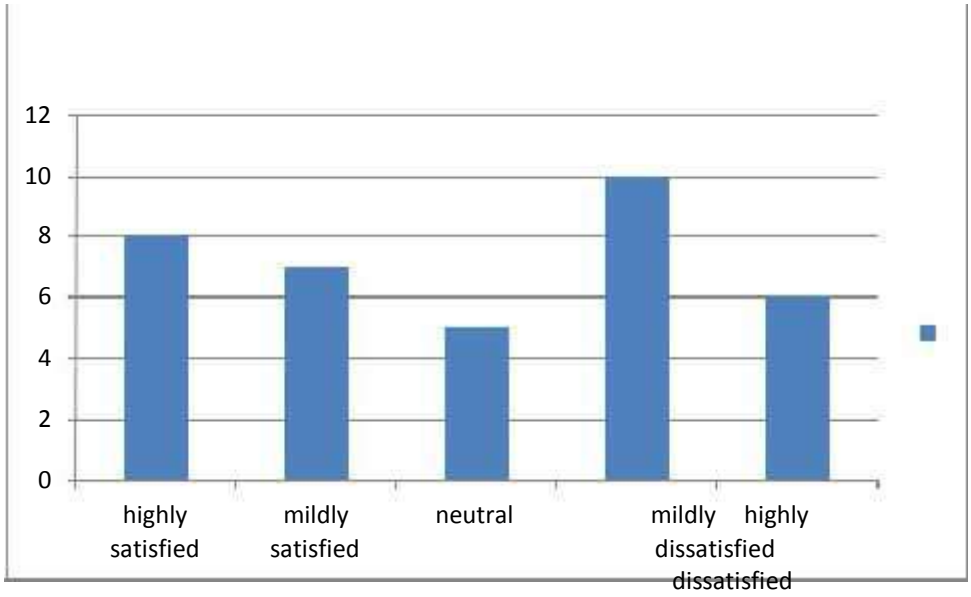
About 82-84% of the pedodontists showed positive response for the restorative procedures like stainless steel crowns , polycarbonate crowns, class II alloys on deciduous teeth, acid etch resin techniques, properties of resin materials, radiographic diagnosis , 18-22% showed mild and highly dissatisfied response to the restorative procedures .

Table 4: Ability to diagnose and treat developing and treat occlusion utilizing interceptive procedures until final development of permanent dentition.



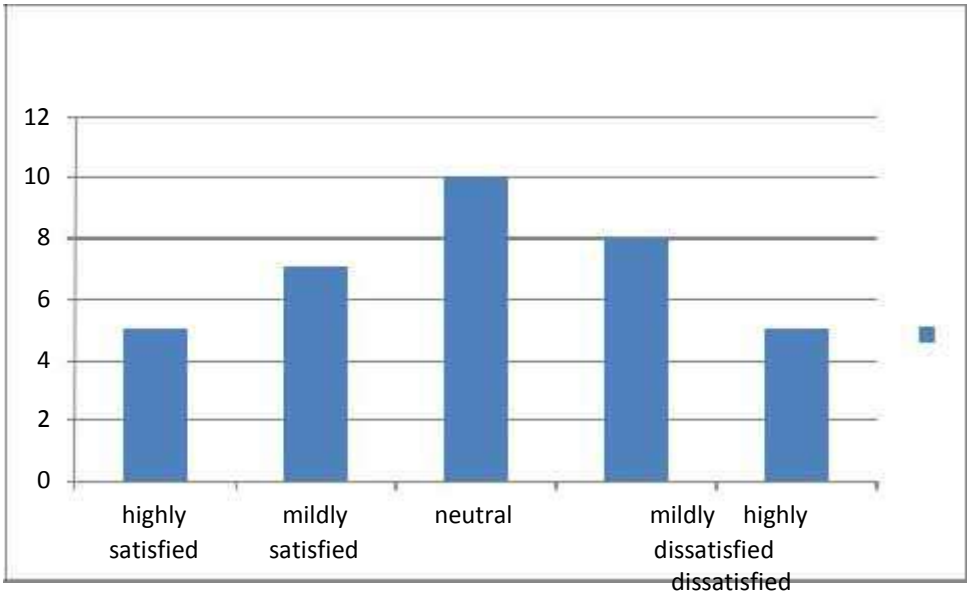
About 68-72% of the pedodontists show highly and mildly satisfied response to the interceptive procedures like removable appliance, techniques of guidance of eruption, cephalometric analysis, correction of ectopic eruptions, minor tooth movement with fixed appliance, crossbite diagnosis and correction. 29% of the pedontists showed mildly dissatisfied response to the interceptive procedures.

Table 5: Knowledge and ability to render competent oral care for the special child with pediatric or medical considerations.



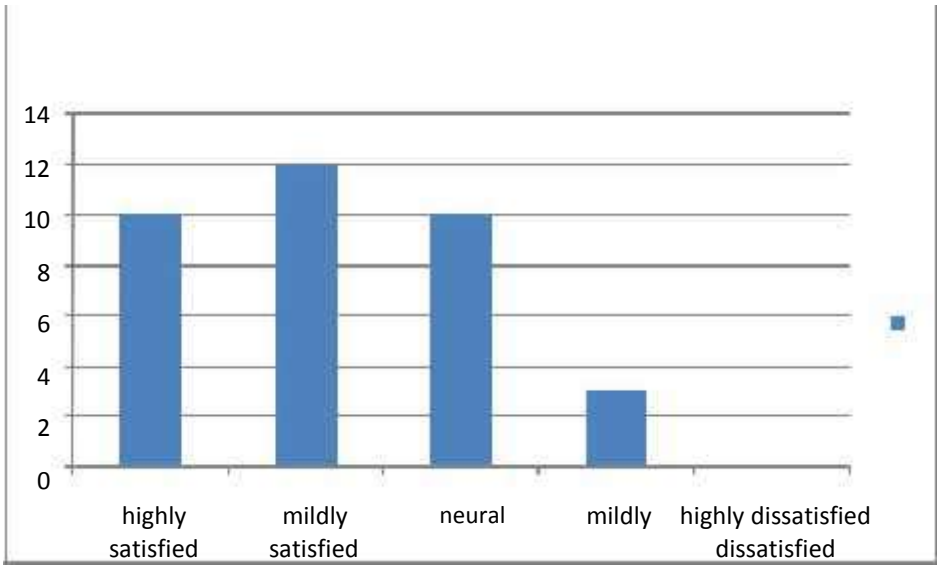
32-38% of the pedontists showed highly satisfied and mildly satisfied results in the diagnosis and treatment of herpecric and aphthous ulcerations and nearly 61%-70% of the pedodontists showed mildly dissatisfied and highly dissatisfied results in precautions in positive cardio vascular history , hemophilia- dental approach to treatment, epilepsy and dental treatment, mentally restarted patient.

Table 6: Knowledge and competency in the utilization of pharm logic methods of patient managementinpediatricdentistry.



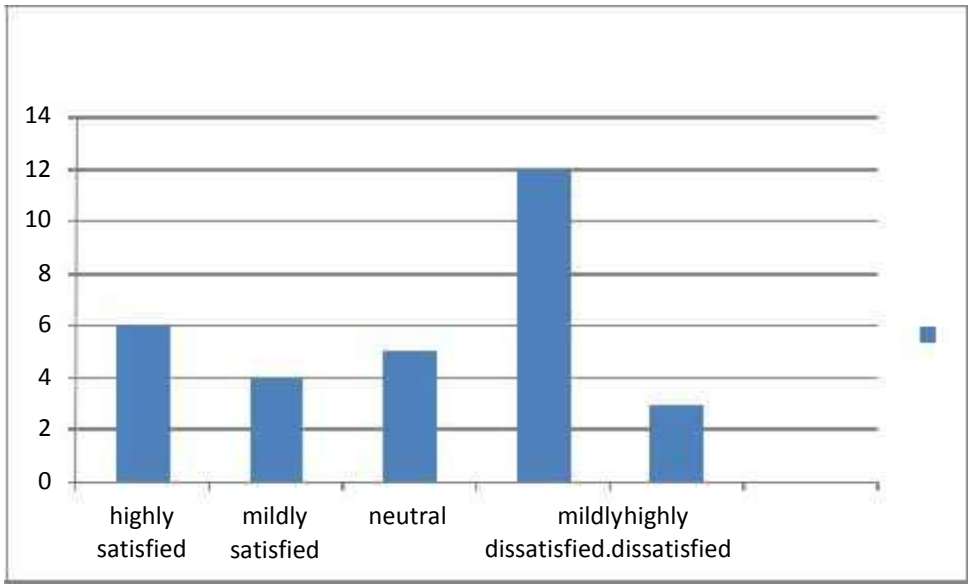
32-37% percent of the pedodontists showed mild and highly satisfied with the utilization of the pharmacological method , while nearly 56-68% of the pedodontists showed mildly dissatisfied and neutral response to methods like oral sedation, biomedical aspects of narcotics, intramuscular sedation techniques, emergency drugs and techniques, intravenous sedation techniques.

Table 7: Ability and knowledge in the hospital oral health care:



83-86% of the pedodontists showed highly and mildly satisfied reports in the oral health care aspects like biomedical aspects of general anaeatetics, knowledge of hospital protocol and experience in admistering the general anesthesia. While remaining 20-22% of the pedodontists show neutral response and mild dissatisfied response to the oral health care.

Table 8: Knowledge and experience in academic pedodontics



Nearly 35-40% of the pedodontists showed highly satisfied and mildly satisfied in the academic pedodontics in topics like ability to evaluate literature, working knowledge of basic pedodontic literature. And nearly 65-71% of the pedodontists are mildly and highly dissatisfied with the teaching experience in the didactic and the clinical environment and mainly in conducting experimental and or clinical research.

Discussion

The indicated differences in degree of satisfaction may not reflect differences between the programs, but may be due to the varied aims and expectations of the respondents choosing the different programs. Attitudinal surveys are affected by respondents' feelings, beliefs, knowledge, and predisposition towards a subject. In a similar manner, the non-respondents may represent a population different in attitude towards their specialty education. In consideration of these facts,

survey methodology incorporates various design measures to minimize bias and increase the usefulness of the obtained data. Specific measures incorporated in this study were multiple inquiry items, Likert-type attitudinal scale, population control, response anonymity, transmittal letter, and significance levels. The survey indicates pedodontists are generally satisfied with their educational experiences related to behavior management, restorative dentistry, pulp therapy, traumatic injury and interceptive orthodontics. The reduced satisfaction level in prevention/patient education suggests a general desire for increased experience in these areas during specialty education. The survey also indicates less satisfaction in the areas of academic pedodontics like the developing and conducting experimental and or clinical research, and also in special child and any kind of pediatric considerations like the epilepsy in dental treatment, mentally retarded patients.

The reduced satisfaction levels related to sedation indicate pedodontists in general desire increased experience in child sedation during their training. University degree programs may require particular improvement in providing such experiences due to significantly over satisfaction levels than other groups[14,16,17]. Combined with similar reduced satisfaction levels concerning treatment of the special child and hospital dentistry, particular consideration by university degree programs may be warranted towards treatment of the more unusual or difficult-to-manage child. Academically related topics such as literature review and teaching experience appear to receive satis- factory emphasis in the various program types. However, the perceived attitudes of the pedodontists indicate hospital and university certificate programs might benefit from increased research experience[21]

Conclusion

A survey was designed to evaluate the degree of satisfaction perceived by pedodontists towards their specialty education. The data-based inquiry items were correlated to the various program settings. The respondents indicated*:*

1. Positive satisfaction levels in relation to behavior management, restorative dentistry, pulp therapy, traumatic injury, and interceptive orthodontics.
2. Reduced satisfaction levels in the areas of prevention/patient education and child sedation.

3. Significantly lower satisfaction levels for pedodontists in treatment of the special child, hospital dentistry, and conducting experimental and clinical research.

Although no definitive and specific recommendations can be derived from the data, the findings may serve as a reference base for future studies and individual program self-analysis. Prospective students of pedodontics may find the information useful in evaluating and matching pedodontic programs with individual.

Attitudes of General Dental Practitioners towards Biopsy Procedures - A Survey

N. Vidulasri[1], Gheena[2],Caroline Jacob[3],
Graduate Student[1], Reader[2], Department of Oral Pathology[2],
Senior Lecturer[3], Department of Periodontics[3],
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,
Saveetha University, Chennai, India

Abstract

Introduction: Biopsies are one among the diagnostic procedures in detection of malignancy, but are not conventionally performed in dental practice due to the fear of medico-legal complications, unfamiliarity with the technique and the misconception of it being a predominantly specialist procedure. This survey was therefore aimed to explore the knowledge, attitudes and practices of general dental practitioners towards biopsy procedures.

Materials and Methods:A self-designed questionnaire was administered to 50 dentists comprising of private practitioners and dental surgeons working in public and private institutions. The first part of the questionnaire included the demographic details of the dental practitioner while the second part explored the knowledge, attitude and practices towards oral tissue biopsies.

Results: All general dental practitioners (GDPs) (100%) believed it was important to perform biopsies for the diagnosis of oral lesions. 82% maintained that it should be done for all premalignant, malignant and cystic lesions, while 18% suggested that it should be performed only in premalignant and malignant lesions,26% performed the biopsy on their own. Regarding the knowledge of various biopsy methods, 78% were aware of all biopsy techniques. Reasons quoted for not performing biopsy were the lack of experience (38%), lack of confidence (12%) and inadequate patient cooperation(12%). 96% dentists felt the need to update their knowledge regarding oral lesions and biopsy procedures with the preferable use of information.

Conclusion: The GDPs enrolled in this study were adequately aware of oral screening and biopsy procedures but felt reluctant to perform them, which suggests that dental education programmes are needed for GDPs in oral pre-cancer/cancer detection as well as screening and diagnostic procedures.

Key Words:*Tissue specimen, oral lesions, histopathology, differential diagnosis*

Introduction

Biopsy technique is a diagnostic procedure which involves removal of tissue from affected area in the living organism for microscopic examination and providing appropriate diagnosis.(1)The diagnoses of many of the oral lesions require additional investigative procedures, out of which biopsies plays an important role.Biopsy and subsequent tissue examination helps in diagnosing the histological characteristics, level of differentiation, and the extent of the suspected lesion.Although dental practitioners may arrive at the clinical diagnosis of a lesion with various diagnostic tools, it is conventionally confirmed by histopathological examination.(2) Oral biopsies are indicated in:

- white lesions(leukoplakia, lichen planus, leukodema)
- red lesions (erythroplakia, atrophic lichen planus)
- vesiculobullous lesions (pemphigus, pemphigoid),
- soft tissue lesions (fibroma, mucocele),
- lesions on gingiva (pyogenic granuloma, gingival enlargement), periapical cyst(3)

Dentists are the first to encounter such changes in the oral cavity, they should take the responsibility to counsel, diagnose and effectively treat the condition in its initial stages.(4) Dental professionals should detect and recognize oral lesions and inform the patient accordingly so as to provide early diagnosis and treatment. Though certain patients are not convinced with the biopsy procedures for some reasons, it should be worth convincing the patient by informing the benefits of an early diagnosis of an lesion.General dentalpractitioners (GDP) must therefore be well-versed in performingsimple oral biopsies to diagnose oral lesions, preservingtissue specimens and generatingthe subsequent report.(5,6)Despite the benefits of performing a biopsy, it is observedthatthepractice of oral biopsy is not as widespread in dental practice predominantly due to the unfamiliarity of the procedure and its documentation.(7) Early identification of oral cancerous lesions reduces rates of morbidity, mortality and mutilation, increases the quality of life and lowers treatment costs(8). Incidence of oral cancer is rising in most countries, with squamous cell carcinoma (SCC) accounting for 95% of oral cancers, and it is associated with avoidable etiological risk factors.(9,10)Awareness, clinical findings and the experience of dentist form the basis for successful judgment and diagnosis of a particular condition(11).Oral lesions may be overlooked due to lack of awareness of the disease or the presence of subclinical changes in a clinically innocuous oral mucosa(12).However, in spite of the wide range of information

available from routine oral biopsy and histopathological examination, biopsy procedures remain unpopular among GDPs.Therefore, theaim of the study was to explore the knowledge, attitudes and practices of general dental practitioners towards biopsy procedures.

Materials and Methods

A self-designedquestionnaire was administered to a convenient sample size of 50 dentists comprising of private practitioners and dental surgeons working in public and private institutions. The first part of the questionnaire included demographic details such as the age, sex and professional qualifications of the GDP while the second part explored the knowledge, attitudes and practices towards the diagnosis of oral lesions and performance of oral biopsies. The questionnaire comprising of total 21 questions, was distributed among the practitioners.
The questions were devised to obtain information on:

- Awareness about importance of biopsies in oral lesions
- knowledge and practical skills in diagnosing lesions, knowledge about biopsy of oral lesions
- Knowledge of tissue handling and preservation of the samples
- Reasons for not performing the procedures
- Proximity to an Oral Pathologist

Results

Among the 50 general dental practitioners, 23 males and 27 females participated in the survey. All GDP(100%) believed it wasimportant to perform biopsies for the diagnosis of oral lesions.76% (n=38) of GDP did not perform biopsies in their clinical practice except for the remaining 24% (n=12) as seen in Fig.1.

On asked about the question regarding lesions that required biopsy, 82% maintained that it should be done for all premalignant, malignant and cystic lesions, while 18% suggested that it should be performedonlyin premalignant and malignant lesions.(Fig. 2)On asked about what they do for lesions requiring biopsy,48% (n=24) of GDPemployed a specialist to perform the biopsy, while 24% (n=12) referred their patients to a higher centre. The remaining 26%(n=13) performed the biopsy on their own (2%)claimed that they referred their patients to super speciality centers and 24% said that they would either call a specialist or refer them to a higher center based on the condition of the lesion.(Fig. 3)

Regardingthequestion about their knowledge of various biopsy methods as in Fig 4,

78%(n=39) were aware of allbiopsy techniques. However, only 14%(n=7) were awareof excisional biopsy, 6% were aware of only incisional biopsiesand 2% were only aware of fine needle aspiration.

The common reasons quoted for not performing biopsy was that 38% said it was due to the lack of experience, 12% of GDPs said it was due to lack of confidence to interpret the results for the particular lesion and 12% reported that it was due to inadequate patient cooperation for the biopsy procedures. The questionnaire also sought the opinion regarding the preservation of the specimen after removal of tissue, of which 62%(n=31) believed that preservation in formalin was the most ideal technique while 38%(n=19) agreed that the tissue sample could be preserved both in saline and formalin as seen in Fig 6.

Majority of GDPs (96%)dentists felt the need to update their knowledge regarding oral lesions and biopsy procedureswith the preferable use ofinformation via journals, the internet and workshops which is seen in Fig. 6

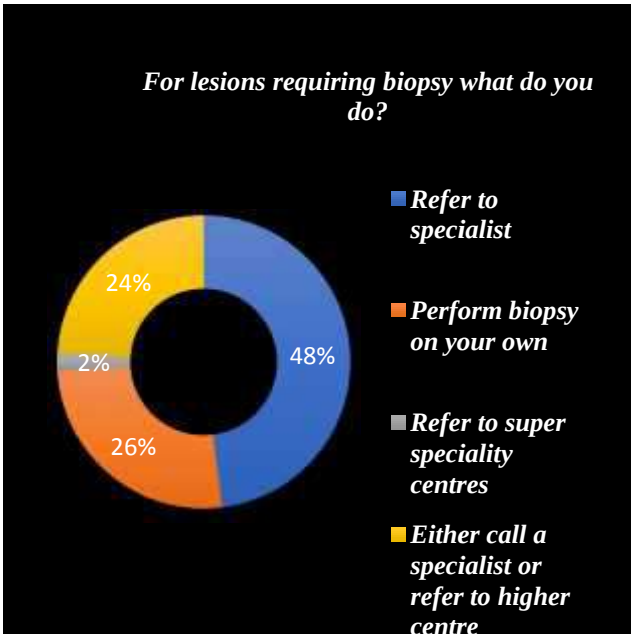

Figure 3:Percentage of dentists who prefer to perform biopsy or when referred to specialist

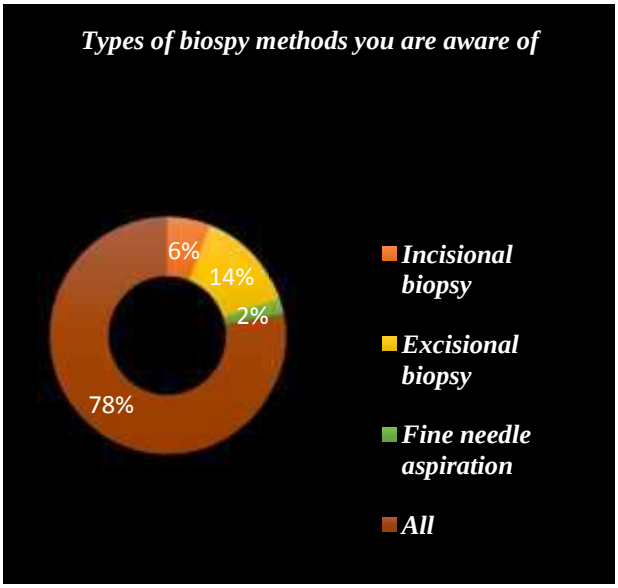

Figure 4: Percentage of awareness of various biopsy techniques

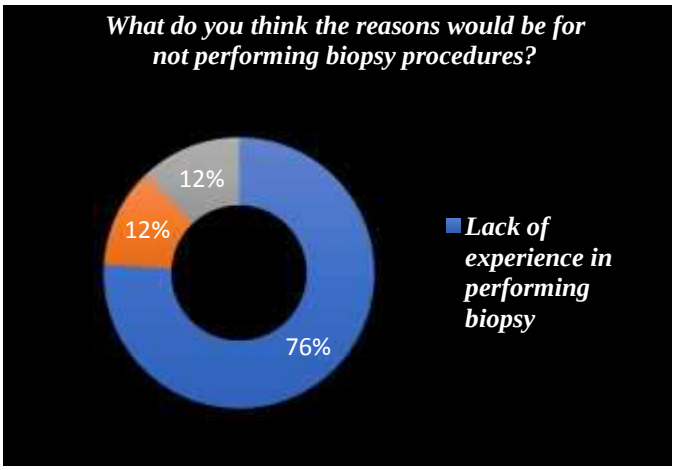

Figure 5: Representation of reasons for avoiding biopsy procedures

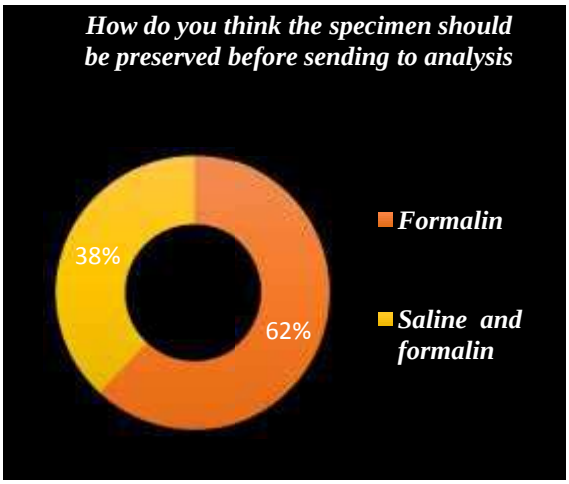

Figure 6: Representation of biopsy sample preservation

Discussion

Biopsies play a prime significance in diagnosing oral lesions (4) and there have been conflicting suppositions concerning if GDPs can perform biopsies. Certain GDP think that performing incisional and excisional biopsiesfor suspicious lesions will help in early and accurate diagnosis (4-6)while others contend that those suspicious lesions should have to be instantly referred.(5,6)Although most dentists prefer to refer biopsy cases to a specialist or a

referral centre, most believed that routine biopsies are well within the scope of a GDP as this would provide direct access to prompt management.Most GDPs who took part in a study (91.4%) believed that biopsy is a vital surgical procedure for an accurate diagnosis with commonly observed lesions that include cysts, benign and premalignant lesions, and malignant tumors. In addition, lesions in the oral cavity are much more accessible compared with lesions in other sites.In a study (4), 97% of students agreed that family history plays an important role in oral cancer and thus the importance of performing a biopsy was unanimously agreed upon by all dentists in order to arrive at a conclusive diagnosis of various oral lesions.Boyle (5) suggested thatthe degree of qualification had little to do with the ability to perform a biopsy. In this survey, 26% respondents performed biopsies on their own which was higher than those reported by Cowan et al. (7) who observed about 12% in Northern Ireland and 15% by Diamanti et al. (8) in Manchester. A study by Warnakulasuriya and Johnson (9) found that 21% of dental specialists in United Kingdom and Seoane et al. (10) revealed that 24.5 % GDPs perform biopsies in Northwest Spain. While in Norway, Berge (11) found that 56% of dental specialists endeavored to perform a biopsy.In the current study 48% of GDPseither called a specialist or referred the patient to a higher centre. This was lesser than those reported by Wan and Savage (12) in Brisbane, where it was seen that 76.2% of GDP referred their biopsy cases to a specialist. This could be due to a few variables like the dread of medico-legal complexities, newness to the biopsy strategy, absence of confidence in individual analytic abilities, misguided judgment that suggests the need for expert opinion or that the GDP may not be prepared to advise the patient that he has disease. 78% of GDP's however, were familiar about excisional, incisional and FNAC types of biopsies. The rest were aware of only one or other of the biopsy techniques. This clarifies the requirement for the GDP to be more compatible with biopsy strategies and their signs and contraindications. This would help them to settle on the sort of biopsy required in singular cases (13,14). The most commonly used fixatives were formalin, glutaraldehyde, and alcohol.(15) Astudy by Murgodstated that after the removal and prior to sending for analysis,(53.73%) practitioners, rightly knew that it had to be sent in formalin; while (29.85%) believed that it could be stored in saline and 11.94%believed it could be preserved in alcohol (16).In this study,62% believed that the tissue sample should be preserved in formalin while 38% stated that either saline or formalin could be used for preservation.This is an important aspect in biopsy procurement forclinicians as tissues that are not safeguarded legitimately produce artefacts which hamper diagnosis.(17-19).Histopathological

examination of 967 biopsy specimens revealed that, 43% of clinical diagnosis made by dental surgeons were incorrectin a study by Franklin and Jones (17) who estimated that 85% of dentists in their region did not send biopsies for histological analysis. The rationale for this could be that the excisional biopsy of lesions they consider to be clinically apparent such asmucoceles, fibromas or periapical granulomas may only be considered for treatment. Thus, altered tissue after removal from the oral cavity should be sent for histopathological examinationto arrive at a final diagnosis.(18)In doubtful conditions the patient should be referred to a specialist with expertise in the diagnosis and management of oral lesions.In a study it was observed that 89% dentists did not think histopathologic analysis was required for all biopsied lesions and also stated that 48.09% of GDPs do not examine mucosal lesions on routine basis ignoring the fact that early detection has better prognosis for patient.(19)Incipient lesions are easily detected in the oral cavity because of accessibility of oral cavity for examination and detection. Both the patient and the professional are associated with causes underlying a delay in definitive diagnosis.(20) In many cases patients are unaware of the presence of early asymptomatic lesion or they just ignore the condition by taking self medication.

In a study it was found that 91.4% of dentists appreciated the diagnostic importance of oral biopsy while only (19.8%) indicated that they perform an oral biopsy in their daily practice. (21).This aspect was also noticed by Wan and Savage (22), where 58.1% of GDPs did not feel competent to undertake any biopsies mainly due to lack of experience and practical skills, Diamanti (23) reported 25% of GDP’s said they did not feel confident to perform biopsies while Greenwood et al. (24) found that only 21% of GDPs were ready in carrying out biopsy techniques.

Anurada (25) suggested that 90% of GDP’s felt the need to update their knowledge regarding various pathological lesions and biopsy procedures. In certain studies it was stated that when GDPs were asked how they intended to update their knowledge, 59% of them preferred to attend workshops or CDE programmes, 22% of them by attending conferences, 10% of them through internet and 9% of them through journals (26-28). However in our study, 96% ofdentists felt the need to update their skill-set regarding oral lesions and biopsy procedures, which they believed could be enhanced byaids such as journals, online content, conferences and workshops. From several studies it was concluded that there is a need for including clinical abilities workshops when instructing on oral biopsy techniques, as it is a

supplementary but essential educational resource and supervised clinical procedure to be performed on real patients. (29,30)

Conclusion

With the exponential growth of dental science, dentists need to update their practices according to the best available scientific evidences. It is suggested that the frequent use of biopsy in dental practice will reduce the number of successful lawsuits brought for delay or failure to diagnose.The role of general dental practitioners and histopathologist in the evaluation of tumour specimens has become complex in the last 10- 20years and will continue to develop in the decade ahead, thus proper diagnostic aids should serve the purpose of diagnosis such conditions.Dental practitioners are not well-informed about the diagnostic importance and need for biopsy procedures.There may be a fear factor working in the minds of dentists about losing the patient who has been presented with a chief complaint unrelated to his mucosal lesion, if in case a biopsy procedure is advised or performed, or even if the patient is referred to a specialist for managing such a lesion.Knowledge about recent methodology in diagnosis, treatment and precaution measures in oral cancer is very essential for improving the quality of life in patients with oral cancer .In order to help GDPs detect suspicious oral lesions, continuing dental education programs pertaining to the practical aspects of oral cancer should be conducted.

Awareness about Dental Implants among Patients Attending Dental Treatment

Sameer Mohideen Gani[1], Marian Anand Bennis[2], Aravind Sivakumar[3]

Graduate Student[1],Senior Lecturer[2], Department of Prosthodontics, Senior Lecturer[3], Department of Orthodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Since the introduction of implants by Brånemark in the 1960s, oral implants have become a reliable treatment option for the replacement of missing teeth. The physical and chemical properties of implant materials are well-reported and documented factors that influence the clinical outcome and the prognosis of implant therapy. These properties include the microstructure of the implant, its surface composition and characteristics, as well as design factor. An ideal implant material should be biocompatible, with adequate toughness, strength, corrosion, wear and fracture resistance. The design principles of the implant should be compatible with the physical properties of the material. Materials used for the fabrication of dental implants can be categorized according to their chemical composition or the biological responses they elicit when implanted. From a chemical point of view, dental implants may be made from metals, ceramics or polymers.The objective of this study is to understand the awareness about dental implants among patients attending dental treatment.

Materials and Methods: This is a survey based study. This cross sectional survey has been conducted among patients visiting the outpatient department of Saveetha Dental College and Hospitals. A questionnaire was designed, regarding pattern of awareness about dental implants for the patients to assess the knowledge of the patients who are attending dental treatment. This questionnaire was distributed among 250 patients. The data was collected, tabulated and analyzed.

Result: Out of 100%, 59.2% of patients think its necessary to replace the missing teeth, 20.4% think if replacement is needed if space is available and other 20.4% think there is no need to go for an replacement.46.4% people think only rich people should go for an implant, while other 33.6% think its suitable for anyone who has a missing teeth. Out of 250 patients 65 patients (26%) are very confident about the success of an implant, 94 patients (37.6%) patients are confident about the success rate. Another (25.2%) 63 patients are not sure about the success of an implant, while 28 patients (11.2%) are very doubtful about the success rates.

Conclusion: Majority of patients had a thought that implants are teeth replacement options for the rich and not middle class individuals whereas 33.6% of patients thought that implants can be placed for any individual with a missing tooth and sufficient bone density and does not concern the economic status of the individual.

Most of the patients were willing and eager to know more about implants as teeth replacement options whereas 34.8% of patients did not show any significant interest.

Key Words: *Dental implants, Zirconium, Overdentures, Phonetics, rehabilitation.*

Introduction

The aim of dentist is to restore the basic functions of the teeth and oral cavity. Dental implant is an artificial root that is surgically inserted into the jawbone to support a single tooth replacement, fixed partial, complete denture or maxillofacial prosthesis.Modern dentistry aims to restore the patient's normal function, aesthetics, speech and health of the patient attending dental treatment. Dental implantology has transformed into an emerging field in dentistry. It has become increasingly important [1],[2] as majority of patients treated with implant-supported prosthesis have reported improvement in their quality of life, assurance, self-confidence [3] including psychological benefits and moreover conservation of the tooth structure adjacent to the teeth to be replaced.[4] Due to its high success rates and predictability, its clinical implication is increasing.

Implant supported prosthesis has proven advantages like increased masticatory efficiency, maintenance of the bone, improved function, phonetics, aesthetics, etc. The interest in

aesthetically flawless teeth, and also in a closely natural substitute such as an implant supported overdenture has improved.Previously dental implants were used for the treatment of edentulous patients which are primarily associated with improved denture retention, stability, functional efficiency, and quality of life. But currently for the past decade, dental implants are widely accepted as a prosthetic treatment of completely or partially edentulous patients.

Implant treatment is an increasingly popular treatment option with a high success rate. Recently, it has become the focus of the patients' interest hence for dentist, it is vital to assess their level of knowledge with regards to dental implants and whether their perception of dental implants does in fact reflect reality in order to guide patients who do not have the education or background knowledge to make an informed decision between implant supported dentures and removable dentures.[7],[8],[9],[10] Overall aspiration for improved oral health related quality of life has become a truth after the arrival of dental implants. Replacement of missing teeth with implant supported prosthesis has been accepted and rated as a positive experience by patients who have undergone implant treatment.[9],[11] Many studies have been done in different parts of the world with regards to the awareness of dental implants as a treatment option. An overwhelming majority of patients with severely compromised local host bone can be offered implant-supported rehabilitation with a very good prognosis and improved esthetics, phonetics and function.[2],[9],[12],[13],[14],[15],[16],[17] Thus, the aim of the study was to assess the awareness of the patients regarding implant-retained prosthesis as an option for tooth replacement and the knowledge about tooth replacement as a whole including source of information and attitude towards it.

Materials and Methods

This is a survey based study. This cross sectional survey has been conducted among patients visiting the outpatient department of Saveetha Dental College and Hospitals. A questionnaire was designed with questions about the need for replacement of a missing tooth and their willingness to accept the implants as a choice of replacement. The questionnaire was distributed among 250 patients. The data was collected, tabulated and analyzed.

Result

This survey was done among patients attending the outpatient department of Saveetha dental college. Out of the 250 members who attended this survey 131 9(52.4%)were male and 119(47.6%) were female. 50.4% of patient falls under the age group of 20-25 years, 31.2% of patient falls under 18-20 years and 18.4% comes under 25-30 years.

Table 1: Mode of Awareness

Education	**Total (%)**
Upto high school	**19.2%**
Uneducated	**52.8/%**
Masters	**11.6%**
Upto university or above	**16.4%**

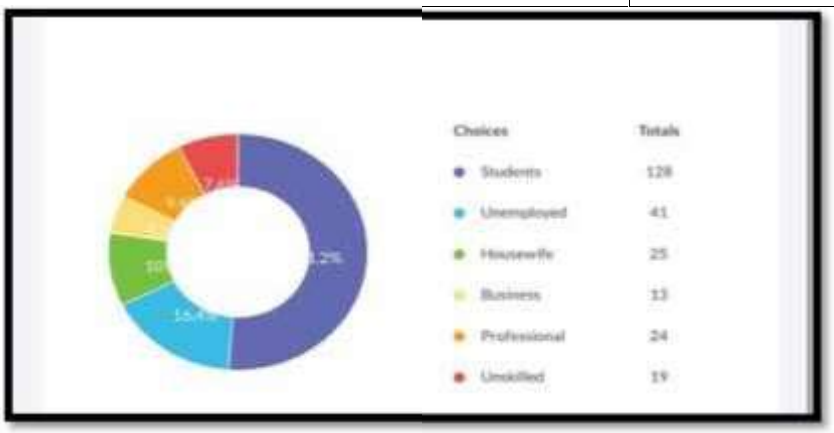

Figure 1: Commonly Asked People

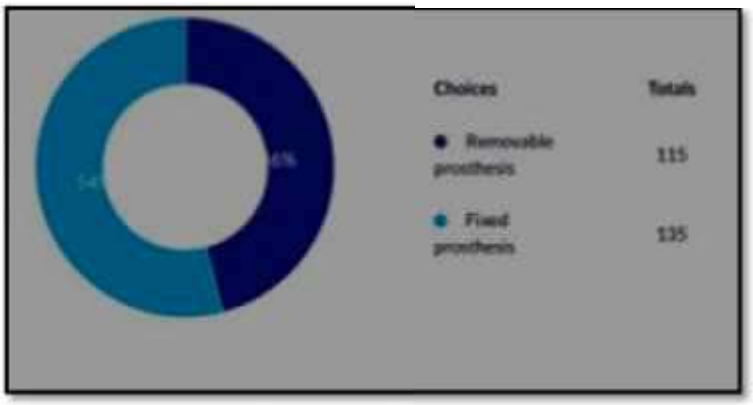

Figure 2: Patient's Preference

Out of 100%, 59.2% of patients think its neceesary to replace the missing teeth, 20.4% think if replacement is needed if space is available and other 20.4% think there is no need to go for anreplacemnet.

Table 2: Mode of Replacement

Methods of Replacement	**Total %**
Crown	28.6%
Bridge	17.2%
Complete denture	24.4%
Removable denture	29.8%

54% patients are comfortable with fixed prosthesis and the remaining 46% are comfortable with removable prosthesis. Out of 250 patients, 167 patients (66.8%) are aware of the term implant and the remaining 83 patients(33.2%) are not aware of the term implant. 40.8% of patients know about implants through dentists 26.4% through friends, 18.4% through books and 14.4% through newspaper. 48% people think its a good method of replacement, while 34.4% are not sure and 17.6% says its not at all a good method of replacement. Dentists have informed about the implants to about 46.4% of the patients while 43.46% patients have not been informed. When asked to all the patients personally whether they are ready to get an implant placed for their missing tooth/teeth,44.4% said yes, 40.8% were doubtful and 14.8% not at all.

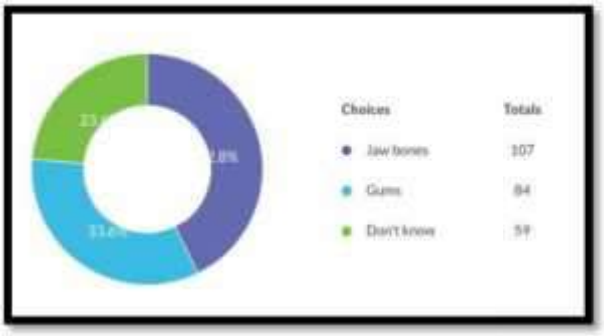
Table 3: Advantages of Implant

Advantages of Implant	Total %
Fixed replacement	21.3%
Looks good	24.4%
Good functioning capacity	23.6%
All of the above	30.7%

Talking about the disadvantages 38% said it was time consuming, 28.4% said they have to undergo surgery, 23.6% said it was costly.

46.4% people think only rich people should go for an implant, while other 33.6% think its suitable for anyone who has a missing teeth. Out of 250 patients 65 patients (26%) are very confident about the success of an implant, 94 patients (37.6%) patients are confident about the success rate. Another (25.2%) 63 patients are not sure about the success of an implant, while 28 patients (11.2%) are very doubtful about the success rates.

45.2% of patients are willing to know more about dental implants and the remaining 34.8% are not willing to know.



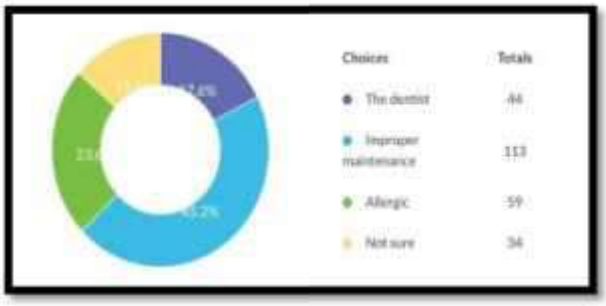


Figure 3: Site of placement Figure 4: Failure of implant

Discussion

Tooth loss may be traumatic and upsetting, and it is regarded as a serious life event that requires significant social and psychological readjustment. The nonacceptance of edentulousness and the individual's feelings about dentures, which have been the traditional way of replacing missing teeth, are important for the acceptance of new dentures.Traditionally, missing teeth are replaced by removable partial dentures, fixed partial dentures (bridges) and complete dentures in cases of complete edentulousness. The need to replace lost teeth with a near-natural successor has encouraged rapid research and advancement in the field of dental implants, especially in advanced economies.

Dental implant is an artificial root that is surgically inserted into the jawbone to support a single tooth replacement (crown), fixed partial or complete denture or maxillofacial prosthesis.It is an ideal option for people with good oral health who have lost a tooth or teeth due to injuries, periodontal diseases, failure of endodontics, etc. It is also used for the treatment of edentulousness and is associated with improved denture retention, stability and functional efficiency and, thus, improving the quality of life of the patient.

This survey was aimed at assessing the awareness about dental implants as a tooth replacement option among patients seeking dental treatment. A total of 250 patients participated in the above survey among which 128 of them were students, 41 patients were unemployed or retired elderly people, 25 were homemakers, 13 business persons, 24 professional workers and 19 were skilled workers. It is seen that majority of patients seeking dental treatment for replacement of missing teeth were students ranging from 18-24 years of age. This can be attributed to the young age and unaesthetic appearance due to loss of teeth.

When the patients were asked about the necessity of replacing missing teeth, a high proportion of patients (59.2%) thought it was very important to replace missing teeth as teeth play an important role in the overall well being of an individual as they take part in mastication, speech and other important functions. 20.4% patients answered that teeth need to be replaced only if they cause difficulty in food intake and if sufficient space is available. An equal proportion of patients also think that tooth replacement is totally unnecessary. The latter mostly belonged in the old age/ elderly category of people.

Majority of patients were comfortable with fixed prosthesis for replacement of their missing teeth while 40% of patients preferred removable dentures as they thought removable dentures to be cost efficient compared to fixed prosthesis.

167 patients were aware about implants as a replacement option for their missing teeth. However 83 patients were not aware about the term implant. Most of the patients who were aware about implants had gained their knowledge about the same through their dentist or through friends or newspaper advertisements. Most of the patients who knew about implants through their dentists were ready to get an implant placed whereas few patients were apprehensive. 14% of patients did not prefer implants due to their cost and technique sensitivity.

Majority of patients had a thought that implants are teeth replacement options for the rich and not middle class individuals whereas 33.6% of patients thought that implants can be placed for any individual with a missing tooth and sufficient bone density and does not concern the economic status of the individual.

Most of the patients were willing and eager to know more about implants as teeth replacement options whereas 34.8% of patients did not show any significant interest.

Abstract

Introduction: Most PMDs are asymptomatic, and the main aim of treatment is to prevent and/or to detect cancer development early. Etiological factors can be identified and patients can be warned of the potential of malignancy. Abstinence from tobacco and alcohol, even after many years of use, significantly reduces the risk of developing cancer. The knowledge of susceptibility to cancer among the general population must be imparted by awareness programs and publications in media. Oral PMDs may be considered a blessing in disguise as they can help in early diagnosis and prevention of oral malignancies which can decrease the burden of cancer prevalence, especially in the youth and working class of the society.
Result: According to this survey, awareness of oral potential malignant disorders was low among patients. It was found that television, internet had played a significant role in patients who were aware of oral precancerous conditions. The aim of this survey is to assess the awareness about oral potentially malignant disorders among dental patients.

Materials and Method: In order to assess the awareness about oral potentially malignant disorders(PMDs), a self -interviewed questionnaire was used to collect information from 100 patients of different age groupsattending the dental hospital, in Saveetha Dental College,Chennai. The questionnaire was designed and included relevant questions to ascertain information on awareness, and sources of information aboutoral precancerous condition.

Result: A total of 100 questionnaires were distributed. The study population consistedof 41female and 59 male patients of different age group.42% of the individuals out of 100 were aware of potentially malignant disorders(PMDs) whereas, 58% did not know about it.

Conclusion: According to this survey, awareness of oral potential malignant disorders was low among patients.

Key Words: *Pre cancer, awareness, lesions, mucosa,patients.*

Introduction

Potentially malignant disorders (PMD) of oral cavity were classified as 'lesions' and 'conditions' by WHO in 1978(1). A precancerous lesion is a morphologically altered tissue in which oral cancer is more likely to occur that its apparently normal counterpart whereas a precancerous condition is a generalized state associated with a significantly increased risk of cancer. However, World Health Organization decided to use the term "potentially malignant disorders (PMD)" to convey that not all disorders described under this term may transform into cancer rather this is a family of morphological alterations among which some may have an increased potential for malignant transformation. These lesions are not only site specific predictors of malignancy but also indicate an increased risk of future malignancies elsewhere in oral mucosa(2).

In the past decades little progress has been made in defining oral leukoplakia. In 1978, the World Health Organisation de ned leukoplakia as "a white patch or plaque that cannot be characterized clinically or pathologically as any other disease" (3). In that communication it was noted, that the term leukoplakia was unrelated to the absence or presence of epithelial dysplasia. In 2005, the World Health Organisation defined leukoplakia as "a white plaque of questionable risk having excluded (other) known diseases or disorders that carry no increased risk for cancer". Both the 1978 and the 2005 definition are worded in a somewhat negative way. Besides, when accepting the view that lichen planus is a potentially malignant disorder, then this disease actually falls within the 2005 WHO definition of leukoplakia.

The prevalence of leukoplakia for all ages is approximately one per cent, with an increasing prevalence in adults. The male-female ratio varies in different parts of the world. Smoking is the most common etiologic factor. Nevertheless, leukoplakia may occur in non-smokers as well. Cessation of smoking habits may result in regression or even disappearance of the leukoplakia in a matter of a few months.The prevalence of oral lichen planus is in general accepted to be approximately 1 per cent. This chronic disorder mainly affects middle-aged

people. The etiopathogenesis is still poorly understood. There is no effective treatment and there are no preventive measures either(4).

When the incidence of oral cancer is set at 5 per 100.000 population per year, then an annual risk of malignant transformation in oral leukoplakia patients of 2% is a four hundred times increased risk. Prevalence of erythroplakia are only available from studies in South- and South East Asia and are as low as 0.02%(5). The annual malignant transformation rate is actually unknown but is much higher than in leukoplakia. There are numerous reported parameters that allegedly predict future malignant transformation of oral leukoplakia. These parameters include previously diagnosed cancer in the head and neck region, older age, female gender, absence of smoking habits, duration of the leukoplakia, clinical subtype (homogeneous versus non-homogeneous), large seize, and oral subsite such as borders of the tongue and floor of the mouth. The use of toluidine blue staining may help to identify high-risk leukoplakias with poor outcome. Other predicting factors include the presence of C. albicans, the presence and severity of epithelial dysplasia, and, in addition, numerous molecular markers, such as aberrant expression of p16INK4a and Ki-67, chromosome instability, and loss of heterozygosity at 9p and mutated TP53(6). Some of the predicting factors mentioned above carry a certain degree of subjectivity. For instance, it may difficult to objectively the clinical homogeneous sub- type. Some clinicians use this adjective only in case of thin , smooth and homogeneously white lesions, while others may apply this adjective also in homogeneously white and homogeneously verrucous lesions. The histopathological assessment of the presence of epithelial dysplasia and the degree of dysplasia is another source of substantial subjectivity(7).

Material and Method

In order to assess the awareness about oral potentially malignant disorders(PMDs), a self interviewed questionnaire was used to collect information from 100 patients of different age groups (convenience sampling) attending the dental hospital, in Saveetha Dental College,Chennai. The questionnaire was designed and included relevant questions to ascertain information on awareness, and sources of information about oral precancerous condition.

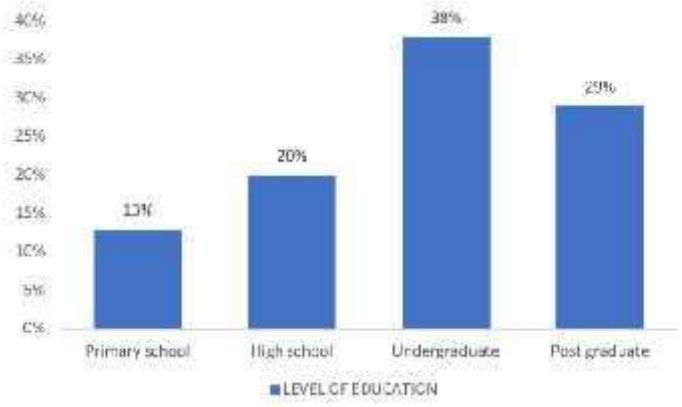
Results

A total of 100 questionnaires were distributed. The study population consistedof 41femaleand 59 male patients of different age group(Tab.1). In terms of education, most of the respondents are undergraduate(38%) , 29% are post graduate individuals(Tab.2),althoughalmost all the individuals had some form of education.

Table 1: Different age group participated in the survery.

SEX	NUMBERS
Male	59
Female	41
Total	100

Table 2: Level of Education of people participated in the survey.



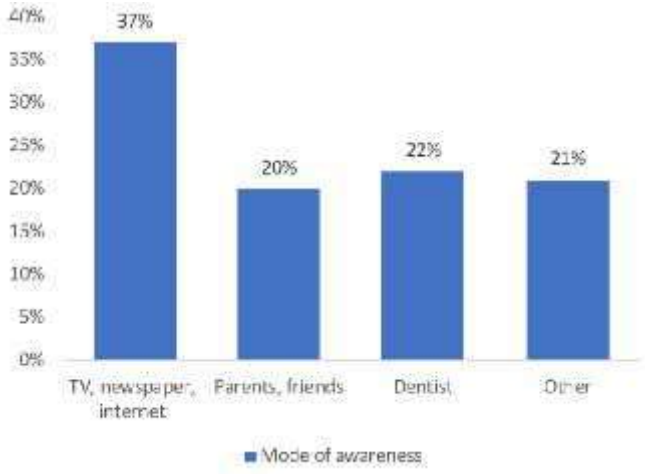
The participants were asked if they had any adverse habits, 43% of the individuals agreed that they have adverse habits which includes smoking, tobacco, pan chewing and 57% of the respondents did not have any adverse habits. 42% of the individuals out of 100 were aware of potentially malignant disorders(PMDs) whereas, 58% did not know about it. The participants were asked if they had any white or red patch in oral cavity and 21% of them hadpatches in their oral cavity. More than 66% of the respondents said that PMD is preventable, however 34% felt it is not preventable.(Tab.3)

Table 3: Knowledge about potentially malignant disorders

PARAMETER	YES	NO
Adverse habits	43%	57%
Awareness about PMDs	42%	58%
Presence of PMDs	21%	79%
PMD preventable	66%	34%
PMD leads to oral cancer	79%	21%

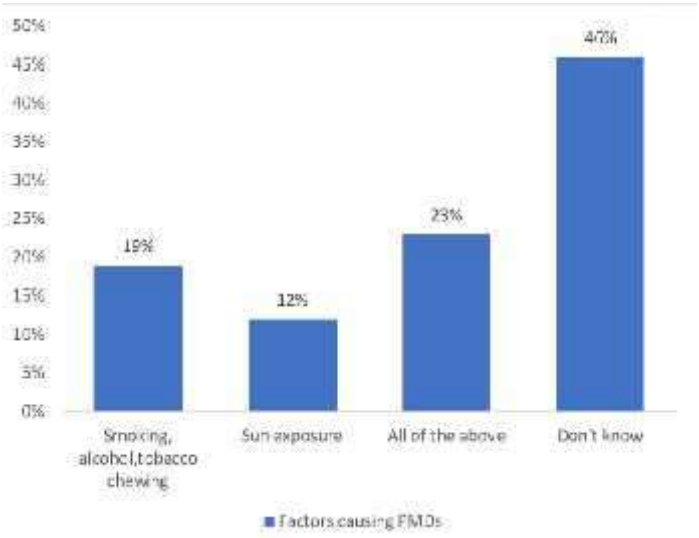
42% of the participants were aware of PMDs through Television,newspaper, internet(37%) and through parents(20%), dentist(22%) and other ways(21%).(Tab.4)

Table 4: Mode of awareness



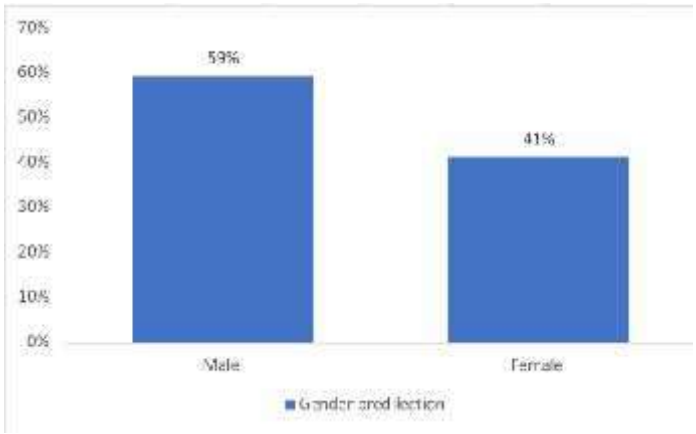
The participants were asked about the factors which cause potentially malignant disorders(PMDs) out of which, 23% of the individuals said that both adverse habits and sun exposure can be the main causative factors and 46% of the respondents admitted that they don't know about the cause (Tab.5).

Table 5: Factors causing PMDs



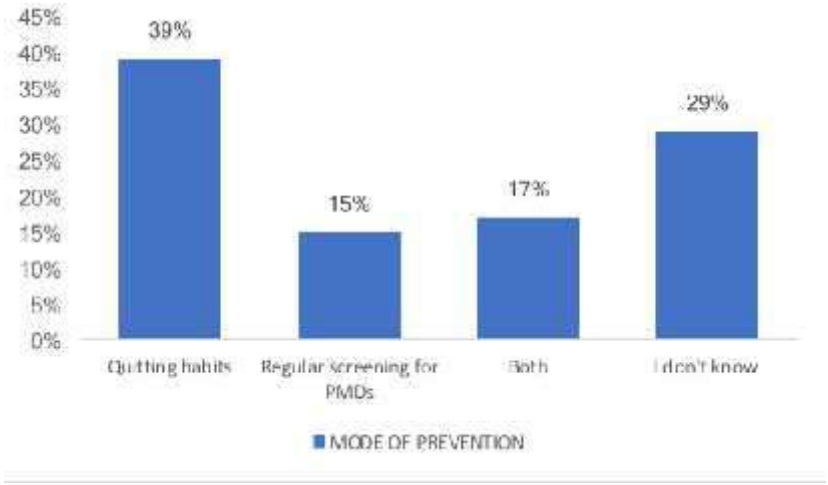
Out of 100 participants, 59% of the individuals said that PMDs are more common in male than female(41%).

Table 6: Graph showing Gender Predilection



The participants were asked about the mode of prevention, 17% of the individuals said that quitting habit and regular screening for PMDs can help to prevent the potentially malignant disorders(Tab.7).

Table 7: Graph showing Mode of prevention



Discussion

Precancerous Condition can be defined as a disease or patient habit which does not necessarily alter the clinical appearance of local tissue but is known to have a greater than normal risk of precancerous lesion or cancer development. A precancerous lesion is a morphologically altered tissue in which oral cancer is more likely to occur that its apparently normal counterpart whereas a precancerous condition is a generalized state associated with a significantly increased risk of cancer.Potentially Malignant Disorders is defined by WHO 2005 as the risk of malignancy being present in a lesion or condition either at time of initial diagnosis or at a future date(8).Oral cancer is a carcinoma that occurs in the oral cavity and belongs to the group of head and neck tumors. Malignant oral cavity tumors account for about 3-5% of all tumors. According to epidemiological data, oral cavity cancer is the sixth most frequent among all types of cancer, and one of the ten most common causes of death, with an incidence of 10 in 100,000 people(9).The most common type is squamous cell carcinoma that makes up 90% of all malignant tumors (10). Oral cancer accounts for about 4% of all malignant tumors in men, and 2 % in women, of an average age of about 60, although an increase in incidence has been recorded recently in people of younger age. The main etiologic factors for the development of oral cavities cancers are smoking, alcohol consumption, sun exposure, liver cirrhosis, dietary deficiencies, viruses, chronic tooth

injuries, etc (11). Oropharyngeal carcinoma belongs to the group of the most malignant tumors, given the fact that the survival rate is about 50%. Although the oral cavity is accessible for visual examination, oral cancers are generally diagnosed late. Lack of awareness in patients and the phase of negation and ignoring the symptoms are the reasons for not seeing a doctor right away, and is considered the “first loss of time”. The “second loss of time” occurs due to lack of awareness of medical and dental professionals and the lack of a timely diagnosis. The “third loss of time” is the period that passes from the diagnosis to the commencement of treatment (12). It is important to reduce the “first loss of time” by increasing awareness of the importance of self-examination, and to shorten the “second loss of time” through education of medical and dental staff.

Oral cancers mostly develop from potentially malignant lesions (precancerouses). Potentially malignant lesions (PML) are lesions of the oral mucosa which are at an increased risk for malignant transformation compared to healthy mucosa. At the congress of the World Health Organization in 2005, “potentially malignant diseases” was suggested as a term for malignant and precancerous conditions (13). The most common precancerous lesions are leukoplakia, erythroplakia, oral lichen planus, and actinic cheilitis. Leukoplakia is a white spot or plaque which cannot be clinically nor histologically characterized as any other lesion, and is not associated with any physical or chemical causal factor, aside from the use of tobacco. According to epidemiological data, general prevalence of leukoplakia ranges from 0.6% to 4.6%. It is most common in men of middle and older age. Cancer will develop from rom leukoplakia in 1-20% of cases. The main activators of cancerization are exogenous factors such as smoking, alcohol, human papilloma virus, or chewing betel (14). According to clinical studies, the most common site of malignant transformation of leukoplakia is the oral cavity floor (15)

Oral lichen planus is immune-mediated inflammatory mucocutaneous disease which occurs in adults, more frequently in females. It occurs in three basic forms (lichen ruber planus, erosivus, and bulosus), and it is classified by its appearance as either reticular, annular, nodular, atrophic, and sclerosus. Premalignant potential of this disease is from 0.4% to 3.3%, particularly for erosive lichen (16).

Actinic cheilitis is a potentially malignant lesion caused by exposure to sunlight. It affects males more often than females, and the most common localization is the lower lip. Off-white

or red changes may be ulcerated. It is estimated that the rate of malignant alteration ranges from 1.4% to 36% (17).

From the above, it was concluded that there may be potentially malignant lesions in the oral mucosa that can turn malignant, and that early diagnosis of PML is of great importance in cancer prevention and early stage cancer detection. If cancer is detected in the initial stage, the potential for remission is 80%.

In a study done by arpita et al, it has brought to light a disturbing aspect that though all the study subjects in this study had high risk behavior, only a handful recognized that their adverse habit could lead to OPMD. Tobacco use and alcohol consumption were appreciated as risk factors for oral cancer by 77% and 60% of the subjects, which was an encouraging finding, but only 14% and 8.6% were aware of these as high risk behaviors for OPMD. Among those who were aware of OPMD, not even half appreciated their lifestyle could lead to development of OPMD. The awareness of other risk factors like poor oral hygiene, actinic radiation, viral infections and micronutrient deficiency was very low. Formosa et al have reported that 92% of their study respondents agreed or strongly agreed that smoking is a strong risk factor for oral cancer, followed by tobacco chewing (84%), tobacco chewing with areca nut (68%), chewing areca nut alone (51%) and exposure to actinic radiation (71%) as risk factors. However, the results for alcohol intake, age, and HPV infection were found to be relatively poor with proportions 33%, 34%, and 23% respectively. In the study by Elango et al 77% of the subjects identified smoking, 64% alcohol and 79% pan chewing as a cause of oral cancer. Ariyawardana et al. reported that 80.7%, 47% and 17% were aware of links with tobacco smoking and alcohol consumption, respectively. Results similar to our study were reported by Amarasinghe et al. where majority of alcohol consumers and smokers and about half of the betel quid chewers surveyed were unaware of the risks conferred by their lifestyles. Pai et al. reported that smokers and past users of tobacco were found to be more aware of effects of tobacco on oral and general health as compared to smokeless and current users but awareness about OPMD remained low in their study as well. This situation calls for specific intervention. There is need for not only increasing awareness regarding OPMD and its presentation in the oral cavity, but the association between adverse life style and increased risk of developing OPMD needs to be stressed. In addition, information needs to be focused on making the tobacco and alcohol users aware of the synergistic potential of these high risk behaviors leading to development of oral cancer and OPMD. For the small number of

tobacco and alcohol users who were aware of OPMD as well as its causal relationship with their adverse lifestyle, it is understood that other factors must be reinforcing continued use. Further investigations have to be carried out to find out the reasons behind the continued practice of high-risk habits, despite knowledge. For this subset, specific counseling is necessary(18).

In a survey done among dental patients in Queensland, Australia, almost all of the participants were with secondary school education(44.7%). However, in this study, majority of the participants are undergraduate individual (38%). In the present study we did not observe any significant differences in the level of knowledge between genders and age groups. This suggests that the education level is the most important variable influencing level of knowledge. Therefore improving knowledge of people especially those with low education is particularly important.

In a study done byjayasinghe et al , identification of alcohol as a potential risk for oral carcinogenesis was low (47.8%). In contrast to the published literature, where the identification of alcohol as a risk factor is high among dental students in this study, only 43.4% of dental students in this study identified it correctly, whereas among medical students it was higher (49.3%). This shows the importance of emphasising the role of alcohol in causation of oral cancer in teaching curricula. Even though they had a good knowledge of some OPMDs, oral erythroplakia as an OPMD was identified correctly only by 18.3% of the respondents. Low awareness of erythroplakia as an OPMD has been reported by others as well. Only 11% knew the overall 5-year survival rate of oral cancer. Knowledge of OPMD and oral cancer among the participants was not satisfactory, and only 10.7% of the respondents had good knowledge of OPMD and oral cancer, and in 12.5%, it was very poor. Similar to the literature from other countries, dental students, especially students in the final year, had a significantly better knowledge ($p<0.05$). About 80% of the medical students had not examined an OPMD or a single oral cancer. A significant number of medical and dental students who have completed clinical training believe that they do not have sufficient knowledge on prevention and detection of OPMD and oral cancer. In a country where OPMD and oral cancers are common, this emphasizes the need for a change in the medical curriculum to incorporate this important area(19).

Ariyawardana and Vithanaarachchi reported in their hospital-based study that over 90% were aware of oral cancer and the figure for potentially malignant disorder was 45%. Higher prevalence of oral cancer in that population and the displayed oral cancer education material, such as posters and pamphlets in public hospitals, into which general public has free access, may be contributory for this high level of awareness(20).

Amarainghe et al reported comparable results for awareness of oral and pharyngeal cancer in their community-based study in rural Sri Lanka. However, this study reported significantly low level(23.0%) of public awareness of oral cancer in the U.K. The study reported in comparison to lung cancer of which the awareness was 97% whereas only 56% of the participants of the survey were aware of oral cancer. Relatively low prevalence of oral cancer may have contributed to the result.Knowledge of the risk factors among the general public is one of the most important parameters for efficacious prevention of OC in the community. In the study, it was found that 48.2% of the respondents were able to identify pan chewing as a strong risk factor while 46.8% identified cigarette smoking as a risk factor. Contrary to this, Park et al in their study based in Western Australia found that only 42 and 5% of patients were able to identify tobacco and alcohol respectively as risk factors for OC. The present study found level of education, the most significant sociodemographic factor affecting patients' risk factor knowledge; participants educated till undergraduate level or higher displayed an overall lesser level of awareness of OC and OPMDs(42%) through television, newspaper(37%), dentist(22%), and others(21%)(21).

According to the statistics, in 2012 the incidence of oral cancer in India is 53842 in males and 23161 in females. Considering the gender in all the age groups, men are more affected than women. In India, men are two to four times more affected than women due to the changes in the behaviour and lifestyle patterns and a study shows that the participants were aware that men(59%) are commonly affected by PMD than women(41%). Detection of oral potential malignant disorders at an early stage ,especially in high risk groups is of utmost importance to prevent further morbidity as they have shown a rate of progression and cancer transformation of up to 17% within a mean period of 7 years after diagnosis. The highest transformation rate is seen in heterogenous erythroplakia and erythroleukoplakia with dysplastic changes. In this study, the participants felt that quitting habits (39%) and regular

screening of oral cavity for PMDs (15%) can help us to prevent potentially malignant disorders

Conclusion

According to this survey, awareness of oral potential malignant disorders was low among patients. It was found that television, internet had played a significant role in patients who were aware of oral precancerous conditions.Potentially malignant disorders is asymptomatic at early stages, and hence, the affected individuals do not seek treatment. Therefore, knowledge of the clinical signs and symptoms of OC is of utmost importance.

Abstract

Introduction

Oral cancer is one of the most common cause of morbidity and mortality today. It is increased by tobacco and alcohol use. Oral cancer is a preventable disease due to its association with well-known risk factors and easy detectability. There is a significant deficiency in the awareness of oral cancer and its risk factors among the public. Raising public awareness could effectively contribute to achieving a significant reduction in the incidence of oral cancer.To study the awareness level about early identification and detection of oral cancer among dental patients.

Materials and Methods

A questionnaire based survey was done about the awareness and knowledge of risk factors, signs,symptoms, prevention and treatment including 50 dentalpatients. Sociodemographic information of the patientswas obtained.

Results

In total 96% of participants have heard of oral cancer. 80% are aware of the risk factors ,65% are aware of the signs and 88% are aware of the prevention and treatment.

Conclusion

There is lack in depth of knowledge of oral cancer. Mass media and health campaigns were the main sources of information. Regular oral cancer screenings should be implemented in chennai.

Key Words: Oral cancer, Symptoms, Signs, Prevention, Treatment

Introduction

The incidence of oral cancer is very high in many parts of the world[1,2], Oral and oropharyngeal cancer is the sixth most common cancer in men and ninth most common cancer in women[3]. It is more common than Hodgkin's disease, carcinoma of the brain, liver, thyroid gland, cancer of stomach[4]. India has one of the highest rates of oral cancer in the world; accounting for one third of the total cancers[5].The major risk factors for oral cancer include tobacco, alcohol, betal nut chewing[6-8].About 70-75% of oral cancer is due to prevalence of consumption of tobacco and alcohol[9,10].Besides these habits, other factors include human papilloma virus (HPV) infection[11],diet[12] and genetic susceptibility. Cancer arises by means of two prominent alterations namely genetic alterations and epigenetic alterations[14].Oral cancer is a preventable disease and cessation of these habits can reduce the risk of cancer within 5-10 years[15]. Although there is recent advances in detection and treatment, it is still diagnosed only in advanced stages[16]. Earlier detection of oral cancer provides early treatment, long term survival and improves the prognosis. In previous studies it has been reported that lack of public awareness is the most significant factor for delaying the treatment for oral cancer[18,19]. Oral cancer awareness is lesser when compared to other types of cancers[20-22].The potentially malignant disorderssuch as leukoplakia, erythroplakia, oral submucous fibrosis, non healing ulcers have been failed to recogniseby the patients which are the early signs and symptoms of oral cancer[23-25].Though the oral mucosa is visually accessible,it's not diagnosed early[26]. There is lack of scientific knowledge on risk factors, signs and symptoms among people which carries a low survival rate[27].Early diagnosis greatly increases the patient's chances of survival as the oral cavity is easily accessible for examination[20].Previous studies conducted in different places showed that awareness on signs, risk factors associated with oral malignancy is generally poor [19,24]. The purpose of this study is to evaluate the awarenessof oral cancer, its associated risk factors, signs and symptoms and to determine the knowledge about prevention and treatment among dental patients.

Materials and Methods

The study design population size was calculated based on the power of the previous study and using G power statistical software.This study included 50 out-patients (21 females, 29 males) aged 17 years and above from Saveetha dental college, Chennai. A questionnaire based survey was created to assess public awareness and knowledge about risk factors, signs

and symptoms, prevention and treatment associated with oral cancer. The survey contained 19questions divided into four parts: socio demographic information (3 questions), awareness and knowledge of oral cancer (3 questions), risk factors of the disease(4 questions), early signs and symptoms of the diasease (4 questions) and prevention and treatment (5 questions).

The response “definitely increases” was defined as correct for the risk factors questions. A “risk factor knowledge score” was given summing the number of correct responses to the four items and the results were evaluated into fourcategories: 0,1,2, 3 and above. The response “definitely yes and probably yes” was defined as correct for all the early signs questions. An “early signs knowledge score” was given by summing the number of correct responses to the four symptoms and the results were evaluated into four categories: 0, 1, 2, 3 and above. The response “yes” was defined as correct for the prevention and treatment. A “prevention and treatment knowledge score” was given summing the number of correct responses to the five items and the results were evaluated into four categories: 0,1,2,3 and above. Point of risk factors (PRF), point of early signs (PES) and point of prevention and treatment (PPT) were obtained for each patient[28].

Results

The study included 50 out patients among them 21(42%) were females and 29(58%) were males. The age of the participants was from 17 to 60 years the mean age being 38. There were 29 participants ageing from 17 to 39 (58%) and 21 participants ageing from 40 to 60 years (42%). The education level of the participants included 23 from high school education (46%), 26 from university education (52%) and 1 from elementary school (2%).

Out of 50 participants (Table 1), 48 participants (96%) have heard of oral cancer and 2 participants (4%) have not heard of oral cancer. Most of the patients have heard about oral cancer through TV, radio, newspaper 48 participants (96%). Very few have got information through internet 2 participants (4%). 41 participants (82%) have not undergone screening for oral cancer and 9 participants (18%) are not aware if they have undergone screening.

Table 2 shows distribution and analysis of PRF, PES, PPT in age groups, older patients have better knowledge on risk factors (85.7%) than younger age groups (75.8%). Prevention and treatment of oral cancer was answered maximum by the younger age groups (100%) and by 95.2% by the older age groups.

Considering the distribution and analysis fro gender (Table 3), there is no significant difference in response between males (87.3%) and females (88.8%). Males have better knowledge on risk factors (86.2%) than females (76.1%). Questions on signs and symptoms were answered better by females (95.2%) than males (82.7%). Table 4 shows groups classified based on education level. Participants with university qualification (89.7%) have answered slightly better than high school qualification (86.9%).

Among the risk factors, smoking was identified correctly by maximum number of participants (44 participants 88%) followed by paan chewing (23 participants 46%), long term trauma due to sharp tooth(4 participants 8%) and eating hot and spicy foods (1 participant 2%). In the sign and symptoms, a wound which does not heal for long time was answered by maximum number of participants (41 participants 82%), then sore and bleeding gums (40 participants 80%), followed by red patch (24 participants 48%) and white patch (22 participants 46%). When questioned about prevention and treatment, 44 participants (88%) answered that oral cancer is preventable,39 participants (78%) answered that cancer is treatable at an early stage , 30 participants (60%) answered that going to a dentist at an early stage can identify oral cancer and 27 participants (54%) answered that there is advanced modalities to detect oral cancer.

Table 1:Percentages of awareness and knowledge about oral cancer.

Items		N (Number)	Percent (%)
Have you ever heard of oral cancer?	YES	48	96
	NO	2	4
Where did you know about it?	Awareness program in TV, Radio & Newspaper	48	96
	Friends	0	0
	Internet	2	4
	Dentist	0	0
Have you undergone screening for oral cancer?	YES	0	0
	NO	41	82
	I DON’T KNOW	9	18

Discussion

Oral cancer is reported as having one of the highest mortality ratios amongst all malignancies[29]. Cohort studies show that oral cancer has risen in all age groups throughout the world in the last ten decades.The prevalence of oral cancer in indiais up to four times higher than other countries[30]. Oral cancer has a vast potential for prevention. It could be prevented by habits cessation and early detection by visual examination which could lead to reduction in mortality[31].

Studies on public awareness about detection and prevention of oral cancer have been conducted in several countries like Northern Germany[32], Florida[33], Sri Lanka[34]and in India it is was done in Gorakhpur city[35], Kerala[36].Although each country showed different results, the overall awareness level was insufficient[20,24,29].This study includes the knowledge and awareness of the patients about risk factors, signs and symptoms, prevention and treatment of oral cancer.

Most of the participants in this study were of younger age group and with high education level. More than 90% of the participants have heard of oral cancer which is better when compared with previous studies[20,37]. 80% of the patients have not undergone screening for oral cancer. This is a drawback in our health system which needs to be improved. Considering the risk factors, smoking was answered to a maximum level (84%) by the participants followed by paan chewing (46%). This may be due to general health campaigns which promote tobacco cessation. This is also because most of the oral cancer patients were described with habits of smoking[38]. Paan chewing was answered next to smoking as it is very common in south Indiaand it was related to social and cultural practices among rural people. Studies conducted in Newyork state and Newjerseyarea have shown that knowledge concerning risk factors was found as 76% for smoking and tobacco use. In Turkey, knowledge related to these risk factors was 57.6%[28]. In another study 80% of the population blamed smoking and chewing tobacco to be the major reason for the occurrence of oral cancer[39]. The results of the current study regarding the knowledge of risk factors was relatively high than the previous studies.In southasian population, most of the squamous cell carcinoma have preceding precancerous conditions arising due to smoking and betel nut chewing whereas in other European countries most of the carcinomas arise de novo[40].

Regarding signs and symptoms, non healing wounds was answered to maximum level of 82% by the participants followed by sore and bleedinggums which is 80%. In the previous studies, 57-66.5% have answered for sore and bleeding gums[24,33]. Painless white patch and red patch were answered to a relatively low level. The signs and symptoms were answered at a lesser level among the older age group. This could be due to fact that elderly personsperceived changes in oral mucosa as a part of ageing. In questions related to prevention and treatment oralcancer was answered as preventable by more than 80% of the participants. It was reported that higher education level and age increases the awareness and knowledge of oral cancer[33].

The sociodemographic level could affect the awareness level about oral cancer.Among the gender, female participants have better awareness about signs and symptoms than the male participants. There were similar results seen in previous studies[41].This is because women are generally more concerned about their health and well being and are aware about any physical changes occurring in the body. In age groups, the younger age group (16-39) have

answered correctly than the older age group (40-60). People with higher qualification and younger age had better knowledge and awareness[42]. The risk of oral cancer is inversely proportional to increasing level of education, occupation and income[43].

The younger age group have better knowledge about the risk factors, signs and symptoms. Mass media and health campaigns were the main sources of information for oral cancer[44].Among the educational level, people with university level of qualification have better knowledge about oral cancer. Education plays an important role in knowing about oral cancer.

The prevention of oral cancer depends on its early detection. Most of the oral cancers are preceded with a precancerous lesion. The American Dental Association has stated that Identifying white and red the spots that show dysplasia and removing them before they become cancer has proved to be one of the most effective methods for reducing the incidence and mortality of cancer[44].

Overall there is lack in depth of knowledge about oral cancer in this study. Though the general awareness of the people is good, focus should be done on conducting various oral health education programs for the recognition of risk factors, signs and symptoms, prevention and treatment. This could be done through oral cancer prevention campaigns based on media advertising such as radio, TV , newspaper articles[28].

Conclusion

The results of this study was better when compared to previous studies done in different populations.This study was first one of its kind to be conducted in Chennai population. Education level and age were significant factors associated with awareness of early signs, risk factors, prevention and treatment of oral cancer. More screening programs should be conducted for early identification of oral cancer.

Awareness of Biomedical Waste Management among Class-IV Employees at Saveetha Dental College and Hospital- A Cross-Sectional Questionnaire Study

Abiraamasri BL[1], Siva Kumar[2], DhanalakshmiRavikumar[3],
Graduate Student[1], Senior Lecturer[2],Department of Oral and Maxillofacial Surgery,Senior Lecturer[3],Department of Pedodontics,
Saveetha Dental College,Saveetha Institute of Medical and TechnicalSciences, Saveetha University, Chennai, India

Abstract

Introduction: The biological waste is any waste that is generated during diagnosis, treatment or immunization of human being/animals or during research activities. Utmost importance of biomedical waste disposal should be known by the individual handling it, as it may be bio-hazardous leading to the spread of infectious diseases.The aim of the study is to determine the awareness regarding biomedical waste management policy and practices, attitude towards biomedical waste management among class IV employees in Hospitals.

Materials and Methods: A cross sectional study was conducted using a questionnaire, distributed to 50 individual at Saveetha Dental College and Hospitals. The questionnaire was used to assess the knowledge of biomedical waste disposal and the result was obtained by grading each correct and incorrect answer given by the individuals.

Results: The study shows that the class IV employees have less knowledge about color-coding and storage of biomedical waste.

Conclusion: The present study concludes that there is an average level of knowledge and awareness about biomedical waste generation hazards, legislation and management among class IV employees.

Key Words: *Biomedical waste, disposal management, class IV employee,cross-sectional study, waste disposal.*

Introduction

Over the years, there have been tremendous advances in the health care system so it is ironic that health-care settings, which restore and maintain community health, also threaten patients' well- being. One major threat arises from poor waste management practices, which pose a huge risk to the health of the public, patients, and professionals and contribute to environmental degradation. Biomedical waste is defined as any waste that is generated during diagnosis, treatment and immunization of human/animal or during research. Dental waste includes cotton, sharp objects, latex, glass, extracted teeth etc. These waste have high potential to cause infectious disease when exposed to healthy human being [1]. In health care centers, wastes produced are categorized into hazardous and non-hazardous waste. 85% non-hazardous waste and 15% hazardous among which 10% is infectious and 5% is non-infectious waste. If the infectious waste gets mixed with non-infectious, the entire mass becomes potentially infectious[2,7]. A total of 80% of the waste generated in the hospitals is composed of general waste while the remaining 20% comprises of infectious, toxic or radioactive waste [3]. Improper waste management, lack of awareness about the health hazards from BMWs, insufficient financial and human resources, and poor control of waste disposal are the most critical problems faced with healthcare waste[4,10] The harmful effect of medical waste on us and environment is enhanced if the appropriate handling of these wastes is not adopted. Improper disposal methods of these wastes may lead to the spread of serious and harmful diseases such as AIDS, hepatitis B and C, and tuberculosis (TB) among the healthcare personnel, waste handlers, patients and their visitors, and community where the waste is indiscriminately

deposited [5,11] .The success of biomedical waste management programme rests on the knowledge and practice of the Health Care Worker (HCW) especially, Class IV workers, as they will be handling BMW most commonly [12]. This study was done at a teaching hospital in Chennai with over 1000 to 1500 outpatients' everyday on an average. About 0.5 to 1tonnes of biomedical waste is generated everyday in the hospital and proper segregation of the waste at source is a challenge. It has a multi-disciplinary biomedical waste management committee to oversee the programme [13].

Materials and Method

A cross sectional study was conducted using a questionnaire study, distributed to 50 individual (46 females and 4 males) class IV employees at Saveetha Dental College and Hospitals. The questionnaire is used to assess the knowledge of the class IV employees about biomedical waste management and disposal. A set of 10 questions comprising of simple questions about color-coding system, waste management, storage and needle stick injury was given to all the class IV employees. [Figure 1] Each correct and wrong answer given by the sample was given a score and the result was calculated accordingly.

QUESTIONS:
1)-Do-you-have-knowledge-about-color-coding-system-in-waste management?
a)-Yes———b)-no

2)-Do-you-wear-gloves-while-you-handle-biomedical-waste?
a)-Yes———b)-no

3)-Do-you-follow-color-coding-in-your-clinic?
a)-Yes———b)-no

4)-Color-coding-for-infectious-waste,-bandage,-gauze,-cotton?
a)-Yellow—b)-red—c)-blue—d)-black

5)-Color-coding-for-plastic-waste?
a)-Yellow—b)-red—c)-blue—d)-black

6)-Color-coding-for-glass-bottles-and-out-dated-medicine?
a)-Yellow—b)-red—c)-blue—d)-black

7)-Color-coding-for-needles,-sharp-objects?
a)-Yellow—b)-red—c)-blue—d)-black

8)-Do-you-know-that-improper-biomedical-waste-management-can-lead-to hazardous-infection?
a)-Yes———b)-no

9)-How long-can-biomedical-waste-be-stored?
a)-24hrs——b)-48hrs

10)-Are-you-aware-of-needle-stick-injury?
a)-Yes———b)-no

Figure 1: Questionnaire used to evaluate the knowledge of Class IV employees

Results

Figure 2 depicts the knowledge of class IV employees in the teaching Hospital towards biomedical waste management. The figure infers that the class IV employees have less knowledge for 4,5,6,7 and 9 questions as per the given questionnaire. The study showed that the class IV employees have less knowledge about color-coding and storage of biomedical waste.Among the given set of questions, 68% of the employees gave wrong answer to “how long the bio-medical waste can be stored”, which showed the highest percentage of wrong answer.

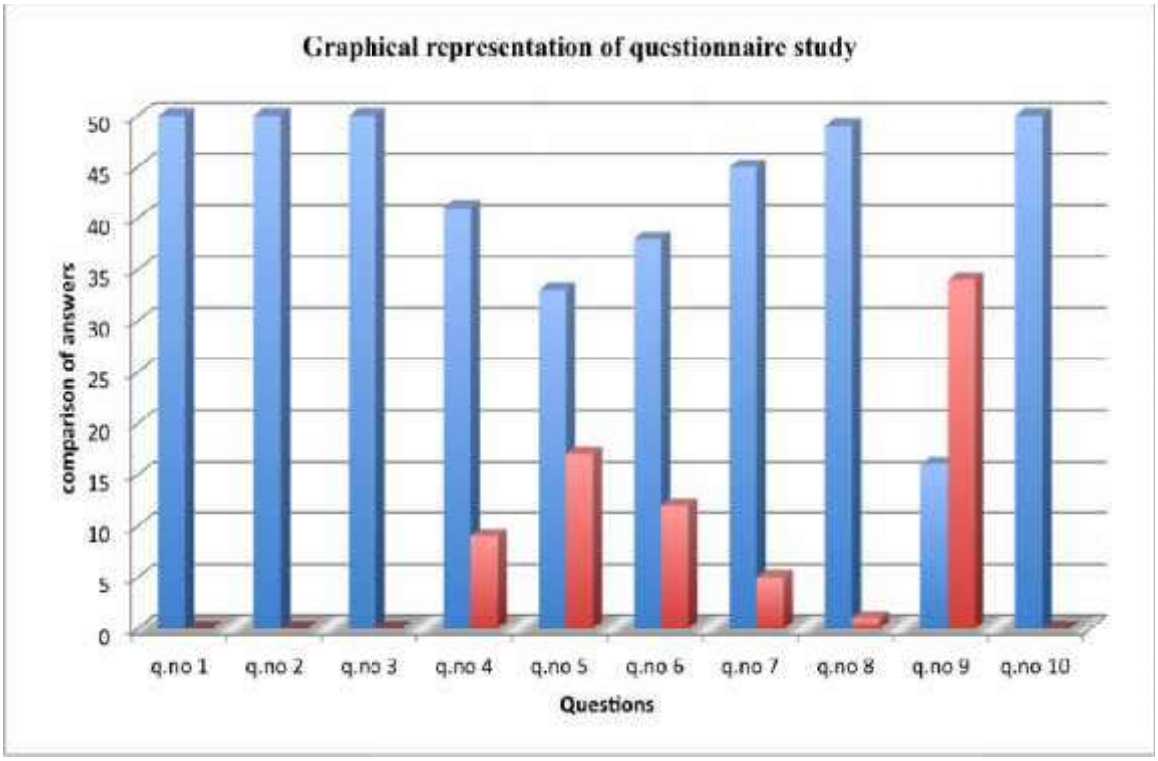

Figure 2: Graphical representation of percentage of correct and incorrect answers provided by the class IV employees

Discussion

The center where the study was at a private teaching hospital, Chennai India. It showed that there was anpoorlevel of knowledge and awareness about biomedical waste generation hazards, legislation and management among class IV employees. Fortunately the level of knowledge and awareness about needle-stick injury was highly adequate. The results of the study was similar to the study done by Alok Sharma [1] .BMW generated by health care establishments can be broadly categorised as general waste, infectious waste, and non-infectious but hazardous waste [25]. Almost 75-85% of waste generated in health-care establishments is non-risk or general waste, which constitutes paper, cardboard boxes, plastic packaging, and kitchen waste . Infectious waste, which includes human anatomical wastes, infectious disposable plastic items and sharps (e.g., needles, razors, scalpels), accounts for only a small fraction, comprising about 10-15% of the total

volume of waste generated in a hospital. However, this small fraction is of the greatest con- cern because it poses a direct threat to the health and hygiene of human beings by transmitting viral, bacterial, fungal or parasitic diseases [25].Low socio-economic status and illiterate people is the most common people working as scavengers, hence it is mandatory to impart knowledge regarding biomedical waste management, including the risks involved in scavenging discarded needles and other sharp items[14] .Hospital wastes are broadly classified as pathological waste, infectious waste, sharp waste, pharmaceutical waste, radioactive waste and chemical waste[15]. Categorizing these biomedical waste by sorting them into color coded plastic bags or container is the effective way to manage biomedical waste[2,6] .In the present study knowledge of sorting biomedical waste based on color coding plastic bags by class IV employees were found to be satisfactory, which was comparable to previous study[7,16].Health hazard associated with poor management in handling biomedical waste include contracting disease like tetanus, rabies, poliomyelitis, meningitis, HIV, Hepatitis Betc. Hence a sound knowledge on heath hazard associated with improper management of biomedical waste will avoid contractingthese highly infectious diseases[2,17] .In our study all the class IV employees were pretty well aware of health hazard associated with poor management in handling biomedical waste, which was found satisfying in comparing to previous study where the awareness of class IV employees were not up to limit[18] .Any type of biomedical waste storage shouldn't be stored beyond 48 hours[2]. Unfortunately most of the participants of this study were not aware of the above-mentioned criteria. Hence a special emphasis has to done in future during training program on biomedical waste[19] .Needle stick injury plays an important role in transmitting deadly infectious diseases like HIV, Hepatitis B. Hence a thorough knowledge on needle stick injury associated issue is a must for any health care professionals. In our study all the participants were well aware about the serious consequences of needle stick injury, which was comparable to previous study [8,20] .A study conducted by Imti,in a tertiary care hospital, Uttar Pradesh, suggested that correct knowledge regarding the same was adequately sufficient across all 4 groups of healthcare personnel which was similar to another study by MathurinLucknow [23].Chudasamin a tertiary care hospital in Rajkot and Madhavi*et al*.

in Khammam,who found 95.4% and 94.8% of the participants were aware of BMW, respectively. Nearly 30.8% of the subjects were aware about BMW rules which were 51.4% in the study by Chudasama.About 1.5% of the total study population had received formal training on BMW management, which is 44.7% and 16.3% in studies of RajkotandKothamangalam,respectively. In the Rajkot study,approximately 96.5% of subjects knew that different colored bags were used for segregation of BMWs whereas almost all the participants (100%) from our study opined the same. Only 6.6% knew correctly about all the colors used for coding. Results from a study conducted in a tertiary care hospital of West Bengalamong the junior doctors show that nearly 76.4% of the subjects knew about various types of color- coded bags for collection of BMW. In a similar study in Rajkot,84.4% of participants identified all colored bags used for BMW collection [24]. Rajkot depicted that about 40.4% of the subjects knew about BMW management categories, which is much higher in comparison with the current study, where it is found to be only 11.6%. In contrary to the present study, about 52.2% and 55.9% of the study population in two studies conducted by Madhavi*et al*. in KhammamandBasuamong interns in West Bengal have a correct knowledge of the same. In another study conducted by Madhukumar and Ramesh in Bangalore,it was only 38.5% [25].The findings of the present study suggest that there is an urgent need to train and educate the dentists and auxiliaries in the dental hospital/clinics of Amritsar through extensive training and re-training programmes. Furthermore, it is also suggested that a proper waste management educational programme should be included in the curriculum for dental education so as to give due importance to this vital issue. Because the study was confined to one major region of North India, further regional studies are required on a larger population to generalize the results, in the formulation and implementation of BMW guidelines. The topic is very relevant to all countries and it is suggested that all public and private healthcare providers should audit the BMW knowledge and practices of their staff at regular intervals. The results of this study will help the hospital authorities to develop a strategy for improving BMW management. BMW management programmes cannot be successfully implemented without the effective knowledge, willingness, motivation, and cooperation from all sections of employees of any health care setting. A

"cradle to grave" approach should be followed in regard to the collection, transportation, treatment and disposal of BMW. There needs to be a sensitization of employees to this issue coupled with effective implementation of rules (such as surprise visits from monitoring authorities and performance based incentives that will facilitate successful implementation of the programme), which is vital for better outcome in future [26]. Nor Masitah Mohamed et al, 2017, concluded that most of the respondents are completely aware of biomedical waste management, which is of paramount importance to reduce the risk of possibly infections material and waste that may be faced the individuals handling these wastes. Among the respondents, 92.5% of them knew the availability of any guidelines laid down by government for biomedical waste management. Union Ministry of Environment and Forests had brought the rules of biomedical waste management into focus under the provision of Environment (protection) act, 1986 [4]. *Sunil Kumar et al., 2012*, about 87.8% of the respondents were aware of various color coding bags that are used to dispose waste. However, a small percentage, approximately 10 respondents were not sure about that. It is statistically significant that 93.3% of the total respondents were following the color coding system to segregate waste in clinics. 94.2% members of the study segregate amalgam in their clinic whereas others were lacking this practice. This study present that dental practitioners had fairly higher good level of attitude and practice. It is observed that more than 95% of the respondents use rubber dam routinely during placing or removing amalgam restorations, and the rest 3.3% of them were not using rubber dam during amalgam restorations. Using rubber dam during operative procedures is important for patient safety. Plus, one study stated that the use of rubber dam during removal of an amalgam restoration had significantly reduced the peak mercury level rise in the patient's plasma [27]. **Gilbert, 2010,** 80% of dentists disagreed that black plastic bags are used to discard human and animal waste. Remaining 5% and 15% of them agreed and were not sure about it respectively. 82.5% of the respondents were disposing infected needles in puncture proof bags, meanwhile 5% had opinion that they should be thrown in red bags and 3.3% chose yellow bags. More than eighty-five percent were using yellow bags for disposal microbiological and biotechnological waste. Next, it was found that 84.3% of the participants were using yellow bags to throw

extracted teeth and only 4.2 percent of them preferred red and black bags to discard extracted teeth .

Conclusion

The present study concludes that there is an average level of knowledge and awareness about biomedical waste generation hazards, legislation and management among class IV employees in South India. Numerous literature review pertinent to biomedical waste management and awareness suggests that this is a perineal problem in many other health care institutions in developing countries. Hence safe disposal of biomedical waste make our whole eco-system safe.Periodical scrutinizing and training are required at all level to make hospital and as well as living environment an health hazard free zone.

Abstract

Introduction: Diabetes is chronic, multisystem disorder with life threatening complications. According to a study by the Lancet, India is ranked among the top three countries having high diabetic populations. Easily managed by glycemic control and simple alteration in lifestyle, it is most often allowed to escalate to the level of complications due to lack of adequate knowledge of the disease and its management. Moreover, regional and socioeconomic differences among rural and urban population of the city could result in skewed perceptions of the disease, in terms of treatment and control. Awareness of these patients is crucial to preventing acute complications and reducing the risk of long term complications, in order to have a positive impact on the morbidity and mortality levels associated with the disease. Representative data on their levels of awareness would help plan large scale diabetes awareness programs to reach and masses. Thus, the study aims to assess and compare rural and urban diabetic population of Chennai city, on their knowledge of Diabetes and associated complications.

Materials and Methods: A cross-sectional community-based study was carried out on 100 diagnosed diabetics, of which 50 belonged to rural areas, and 50 belonged to urban. A predesigned questionnaire pertaining to knowledge, attitude and practices relating to the disease was administered to them. Data obtained from the two groups was compiled and statistically analyzed on Microsoft Excel 2016.

Results: Out of the 100 self- reported diabetic subjects, with mean age of 45-65 years, it was evident that urban residents had consistently higher awareness rates about diabetes mellitus, its

management and complications, compared to rural populations. The results emphasize the interrelation between demography and awareness

Conclusion: Urban diabetic patients are more aware than rural diabetic patients about diabetes mellitus, its management and complications. The study emphasizes interrelation between demography and awareness levels. The results underscore the need to design and implement awareness programs directed at increasing awareness among rural population.

KeyWords: *Diabetes mellitus**,** Awareness, Complications, Rural, Urban*

Introduction

Diabetes is a chronic, multifactorial, multisystemic condition, characterized by hyperglycemia, and associated with disorders of protein, fat and lipid metabolism [1]. The disease is associated with high levels of morbidity and mortality levels, as a result of its micro and macro vascular complications.

India has come to be known as the Diabetic Capital of the world; with studies estimating that every fifth diabetic in the world is an Indian. Statistics reveal that by 2030, up to 79.4 million individuals, in India alone, will be afflicted by the disease [2,3]. This could have grave implications on the social and economic sector of the developing country. With most affected individuals expected to be in the 45 to 64 age group, the disease poses a threat to the productivity of working individuals, the consequences of which will fall on the sustainability of health care financing of the individual as well as the government. Moreover, conventional approaches to management of the disease, and prevention of its complications, are not only expensive, but also largely inaccessible to certain communities [4,5].

No longer considered a disease of the rich, its prevalence its rapidly increasing among the poor in urban slums, the middle areas, and those dwelling in rural areas. With poorer access to education and healthcare among people belonging to lower socioeconomic groups, it is the need of the hour to increase awareness about the nature and complications of the disease, with emphasis on prevention. Evidence based studies support the notion that patients' knowledge on the various aspects of the disease, importance of glycemic control and selfcare practices is key to prevention of complications, as they show more compliance to treatment [6,7].

A correlation between demography and awareness could provide an insight into level of awareness and its adequacy. In this context, the current study was planned with the objective of assessing the comparative level of awareness of diabetic patients residing in urban and rural areas of the city, regarding the complications of Diabetes. The results could help shed light on the areas where emphasis needs to placed in terms of planning public health programs.

Materials and Methods

Study design, setting, and participants:

This is a cross-sectional community- based study, carried out in November 2016. 100 adult patients diagnosed with Diabetes Mellitus were included. Out of 100, 50 were from urban area(Adyar, Nungambakkam) and 50 from rural(Kattupakkam, Karyanchavadi) in and around Chennai city, based on convenience sampling.

Study Tool

A predesigned questionnaire consisting of items on demographic profile including name, age, sex, level of education, employment statusand specific questions to assess their knowledge of complications, practices for preventing and management of complications, as well as their health seeking behavior. The questions used to obtain data were as follows:

1. Are you aware diabetes has complications? Yes/No
2. If yes, what were your sources of information? Physician/Newspaper/Television/Internet/Schools
3. Uncontrolled DM can cause rapid breathing with fruity odour. Yes/No
4. Uncontrolled DM can cause foot ulcers. Yes/No
5. Uncontrolled DM can cause decreased sensation in feet. Yes/No
6. Uncontrolled DM can cause eye related complications. Yes/No
7. Uncontrolled DM can cause kidney related complications. Yes/No
8. Uncontrolled DM can cause increased BP. Yes/No
9. Uncontrolled DM can cause heart disease. Yes/No
10. Uncontrolled DM can lead to stroke. Yes/No
11. Uncontrolled DM can cause coma. Yes/No
12. Which of the following practices do you follow to prevent complications?

a. Wearing closed shoes
b. Inspecting feet for cuts and bruises
c. Regular monitoring of blood sugar levels
d. Losing excess weight
e. Consumption of high fiber diet
f. Regular eye checkups

Methodology

Patients were explained purpose of the study, confidentiality assured and verbal consent was obtained before collection of data. The questionnaire was translated to local language and administered by interviewer.

Inclusion and Exclusion Criteria

All adult patients(aged 18 and above) diagnosed with Diabetes. No patient refused to participate.

Statistical Analysis

Data was compiled and analyzed on Excel 2016 version.

Results

The total number of surveyed participants were 100 (58 Male, 42 Female), as seen in figure 1, of which 50 belonged to rural areas of Kattupakkam and Karyanchavadi, and 50 belonged to urban areas of Adyar and Nungambakkam. The main feature of the study lies in the contrast between the two. The demographic characteristics of the study population is as tabulated in Table 1. The mean participants interviewed were above age of 45 years(73%), followed by those in the 35-45 year age bracket(23%), and only 4% of the interviewed population were below 35 years(Figure 2).

Data was collected and tabulated based on levels of literacy; participants were classified as illiterate, those who had received only primary level of education, those who had received up to secondary level of education, and those who were holders of a degree (Figure 3).

It was determined that majority of rural cohort had received only primary education (50%), while the urban population made up majority of the percentage who had received secondary education and degrees. On tabulating the participants' employment status, it was evident that it was higher among urban than the rural population (Figure 4).

When questioned on their sources of information (Figure 5), for both, the rural and urban population, majority reported their local physician to be their major source of information on the disease

Table 1: Demographic characteristics of study participants (n=100)

CHARACTERISTIC	FREQUENCY(n=100)
Gender	
Male	58
Female	42

Discussion

In this study, we sought to identify, investigate and evaluate by means of exploratory and evaluatory research, the awareness of urban and rural diabetic patients about the disease. The strategy was to administer a questionnaire that would test their knowledge attitudes and practices regarding the disease, its complications and management. The major finding is the general lack of awareness among Chennai residents, with urban diabetic residents much more knowledgeable compared to rural diabetic residents.

The results emphasize a need for imparting community based diabetic education to the general population and to the diabetic population in particular. Chennai, metropolitan city in Southern India, where this study was carried out, is considered a model city in terms of diabetes education activities. It is known for having the first ever diabetic clinic in India, established at the Stanley Medical Hospital in 1948[8]. It is also home to the highest number of government run diabetic clinics in the country. A survey conducted between 2004-07 revealed that over 770 diabetes awareness and free screening camps were conducted as part of its Prevention, Awareness, Counselling and Evaluation (PACE) Diabetes Project [9]. With such impressive credentials, it is a matter of concern when 18% of our interviewed participants were not aware that diabetes posed any serious threat to health. It is also worrisome to think where other cities might stand in terms of awareness when Chennai, after so many measures, shows unsatisfactory results.

The epidemic of non-communicable lifestyle diseases poses a major public health concern, in developing countries such as India. While India is considered the diabetic capital of the world, not enough is done to tackle the problem[10]. With more than 32 million diabetic subjects in India currently, the numbers are expected to double by 2013. Moreover, WHO reports the highest increase of affected individuals to be between the ages of 45-65 years; those falling into this age bracket are usually considered to contribute the most to the economic levels of the country[11,12]. Apart from being a huge economic burden to the country, a price cannot be placed on intangible costs that come with compromised mental health and poor productivity as a result of the disease. Coincidentally, in our study, the mean age of the participants was between the ages of 45-55 years.

Increasing amount of evidence indicates diabetes is a lifestyle disease, easily preventable by simple lifestyle alterations such as dietary modifications and improving exercise behaviors[13,14]. This has been evidenced in studies such as the Diabetes Prevention Programme, the Finnish Diabetes Prevention Study, and the Da Quingstudy[15]. A study by Tan et al showed that early educational intervention improved patients' knowledge and long-term control of the disease. Previous studies have shown a clear link between patient education and prevention of complication of diabetes[16,17].

The fact that self-reported diabetics in the study were generally unaware about the disease and its complications reveals an urgent need to implement programs to impart diabetes education to patients. The regional differences in awareness levels could be attributed to varying levels of education, with those from rural areas having limited access to resources to educate themselves. Those with no formal education had high unawareness rates compared to the educated group, which is in agreement with previous studies[18]. The urban population scored higher on their awareness about complications compared to the rural populations.

Patients were asked to cite their sources of information on the disease. The popular option among both the urban and rural population was the primary care physician. This goes to show that nationwide programs aimed at providing evidence -based guidance to physicians, general practitioners and diabetes educators, ensures improved education and treatment outcome for the patient. Two such efforts by the Indian government, namely Certificate Course in Evidence Based Diabetes Management [CCEBDM] and National Diabetes Educator's Program [NDEP] have made a difference to diabetes care and education[19]. It was also disappointing to note that neither group ranked schools very high on the list. It is crucial that the high-risk group, which is the next generation, is targeted at the level of primary education in school[20]. Early intervention makes a huge difference in disease control and prevention of complications. Maximum individuals from the urban cohort chose internet as their preferred source, which was in contrast to the rural cohort (1%). It was found that those having access to technology had higher health literacy compared to individuals with no access. Accessible technology is crucial to understanding health information and can act as an enabler in diabetes self -care management[21].

A positive correlation has been found between number of complications per patient and patients' healthcare expenditure[22]. The presence of complications weighed heavily on consultation, hospitalization and generally overall costs. A study carried out in Chennai comparing diabetes care costs for patients with and without complications has revealed that the total costs for patients from 2008-09 revealed that total costs incurred by patients without complications of the disease was INR 4493, compared to INR 14691.75 for patients with complications[23]. On investigating different types of complications, it was found that foot complications incurred the highest costs, followed closely by renal, cardiovascular and retinal complications[24].

The results of our study confirm the interrelation between awareness and socioeconomic status of the population. Our study observed that those belonging to a lower socioeconomic status were significantly less aware than those belonging to a higher class. A study by Shobana et al revealed low income individuals bore the highest burden of diabetes[25]. However, it was found in a study done in India on type II DM, from 1998 to 2005 that the urban population showed higher expenditure numbers in terms of absolute terms and as proportion of income [26]. This could be attributed to higher charges for consultation, laboratory tests and drugs, and more expensive treatments in urban areas. These individuals, being economically better off, were found to seek healthcare in private hospitals with better healthcare facilities, and hence, faced better prognosis. On the other hand, those from lower socioeconomic strata could only afford public hospitals funded by the state; these were found to be crowded, with overworked staff and insufficient treatment options. The rural population were found to spend significantly lesser, more due to issues of inaccessibility and affordability, rather than because of a lower need. A study by Rayappa found that unemployed, uneducated people from rural areas were more likely to be diagnosed later as they could not afford to consult a doctor and thus, developed complications [27]. Thus, early detection would provide as a means of cost reduction.

The participating individuals were questioned on their practices of prevention. Misconceptions due to inadequate education on the matter drives misguided perceptions on eating, food habits and exercise behavior[28,29] Changing societal perceptions of health would drive the community towards making healthier life choices. With rapid epidemiological transition to urban areas, compounded by industrialization and rapid pace of growth, developing countries are most affected. A consequence of that being that communicable diseases are replaced by non-

communicable disease[30]. Both cohorts were well aware of the importance of regularly monitoring blood sugar levels. However, urban population were more aware of the practice of losing excess weight. In a developing country such as India, which struggles with malnutrition and poverty, obesity is seen as a sign of good health and prosperity[31]. However, with demographical transitions, obesity poses as a major public health concern, with underweight individuals being replaced by obese. Thus, rural individuals must be made aware of the dangers of excess weight and the benefits of exercise.

The study emphasizes on a need for comprehensive diabetes education programs and community level awareness programs. Mobile health units can be implemented to access remote areas of the country. Mass media campaigns, public lectures and door to door campaigns can also make a difference. There is a need for policy makers to review existing health coverage schemes and concentrate on reducing economic burden of the disease.

The limitation of the study lies in its small sample size. While these values may provide a slice into the scenario in Chennai, extrapolating these values on a larger scale to generalize them to the entire Indian subcontinent may result in erroneous perceptions of the impact of the disease. Thus, the authors recommend more nationwide cross-sectional studies covering larger populations.

Conclusion

The present study provides direct evidence that urban diabetic patients are more aware than rural diabetic patients about diabetic mellitus and its complications. It is imperative that diabetes awareness campaigns are executed to provide education to the masses.

Abstract

Introduction : Oral and Maxillofacial Surgery (OMFS), a dentistry specialty recognized by the Federal Dentistry Board in the mid-1960s, is responsible for the diagnosis, and clinical and surgical treatment of traumatic, congenital, developmental and iatrogenic lesions in the maxillofacial complex. Even today, difficulties are experienced owing to the lack of knowledge of the general public and health professionals concerning the scope of OMFS.Oral and Maxillofacial Surgery had a very strong development in past areas,such as facial trauma,dentofacial deformities,jaw pathologies,temporary mandibular joint disorders and oral cancers. The aim of this study is to assess the awareness among Medical professionals about oral and maxillofacial surgery.

Materials and Methods: The questionnaire was intended to determine the percentage of respondents in each group that made the correct referral of patients presenting with different clinical situations.

Results: The results of our present study shows there is a lack of awareness regarding oral and maxillofacial surgery among general population.

Conclusion: This study is to create awareness and to assess the awareness in Oral and Maxillofacial Surgery among Medical professionals.

Key Words:*Awareness, General population, professionals, Surgery*

Introduction

Oral and maxillofacial surgery is one of the emerging speciality in dentistry. OMFS specialises in treating many diseases, injuries , defects in the head, neck, face,jaws, and the hard and soft tissues of the oral and Maxillofacial region. It is an internationally recognised surgical speciality . In some countries around the world, including the United States , Canada and Australia ,it is a recognised speciality of dentistry. But in others such as the UK and the most of Europe, it is recognised as both a speciality of medicine and dentistry and you need to get both the degree in medicine and dentistry to practice.

The scope of the speciality has also increased vastly as compared to earlier years where it was restricted to mainly dento-alveolar surgery and basic maxillofacial trauma. Currently dento-alveolar surgery, maxillofacial trauma, pathology of head and neck, cleft lip and palate, bone grafting ,facial deformity correction, aesthetic facial surgery, TMJ surgery, implant surgery etc.,are just some of the sub specialities being treated by maxillofacial surgeons all around India.

In spite of all these advances in maxillofacial surgery, it is still vaguely understood by both the dental and medical fraternities . The awareness is even worse among the general population. Previous studies conducted in the USA and the UK have reported that the medical and dental fraternity and the general public are largely unaware of the scope of oral and maxillofacial surgery[1][2]. Ameerally et al [1],conducted a study in England and concluded that up to 79% of general population had not heard of OMFS, and around 74% did not understand its role and scope. Ifeacoetal[3]concluded that most of the medical professionals had heard of this particular speciality, but they were not clear about the clinical expertise this branch could offer. In a study by Hunter[4], it was found that medical professionals, who did not know about this branch, refer their patients for treatment of conditions that overlapped different specialties mostly did not favour the choice of an oral and maxillofacial surgeon.

If the awareness even in developed countries is lacking, the situation in a developing country like India is bound to be worse. We therefore need to study to check the awareness of the oral and maxillofacial surgery among general population in India.

Materials and Methods

Sampling and Survey Instruments and Statistical Analysis

The study was done in Saveetha dental College and Hospital, Chennai, TamilNadu, India to assess the current awareness levels about the oral and maxillofacial surgery inthe Indian society. The randomised cross-sectional study was conducted among the generalpopulation of about 105 participants. A questionnaire was prepared in English, that listed 10general questions which focused on the knowledge about the oral and Maxillofacial surgery.

The questionnaire consisting of 10 questions were given to the participants.The sample of 105 was a randomly selected Group of individuals who would beconsidered to represent the whole population. They were selected after applying a multi-stagerandom sampling method for selection. They were previously asked questions before the actualquestions in the questionnaire in order to avoid bias in our study. The individuals who had anyrelations or friends in the dentistry department were omitted .The data have been collected through pre designed self administeredquestionnaire.The survey had utilised the Surveyplanet website app. Through the app the survey had beentaken, the collected data were organised and analysed . The questionnaire consisting of 10questions were given to 105 participants. The 105 participants were then asked to answer allthe questions. The questionnaires were then reviewed, analysed and evaluated. The results were collected andanalysed using Apple numbers software app.

Objective

The questionnaire was intended to determine the percentage of respondents in each age group that have the correct knowledge about the OMFS.The aim of this survey was to investigate the current level of awareness about OMFS in different age groups.

Results

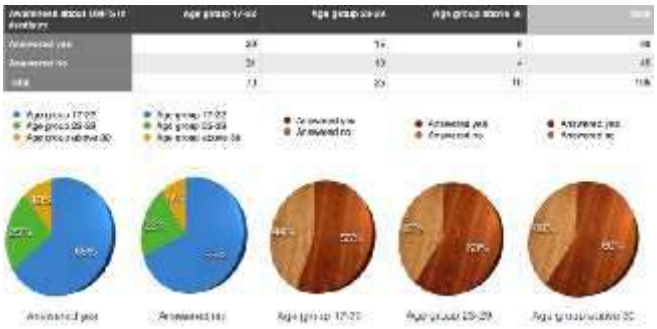
Only the completely filled questionnaires were selected for the study. The incomplete questionnaires were rejected to avoid confusion in derivingthe results .The number of participants were different in all the age groups but the proportion of male and female participants were equal in the age groups. This probably would avoid the inequality in the distribution of the sample size in each agegroup.The demographic data of the participants were analysed. The age group division was to find out the awareness among the general population. Results for the three groups of participants were given in the tables below. In this study also, male participants were more predominant comparing the female participants. In all the age groups, about 60% of male are participants. Of the total 105, 70 belongs to age

group 17 to 22, 25 belongs to age group 23 to 29, 10 belongs to age group above 30.The gender distribution, male and female, was found to be almostequalin all age groups, whereas the predominant gender was male in each age group.(Table1)

About 57% of participants knew about OMFS in dentistry. Among the participants who knew OMFS, 65%are from age group 17 to 22, 25% are from age group 23 to 29,10% from the above 30 age group.Overall , almost 60% in each age group answered yes which shows almost 60% of people in every age group knew about the OMFS in dentistry which may be due to the name factor.(Table 2)

Table 1–Participant's distribution among different age groups.

Table 2–Knowledge about OMFS in Dentistry depending on the age group.



About 63%(66/105) of sample population were aware that a dentist can treat oral cancer. In the category who had answered yes, about 57% of age 17 to 22 were aware that a dentist can treat oral cancer and about 29% of age group 23 to 29 were aware that a dentist can treat cancer . In age group of 17 to 22,about 54% were aware that the dentist can treat oral cancer.(Table 3)

About 64%(67/105) of participants knew that a dentist can do maxillofacial surgery. About 67% Who knew that the dentist can do maxillofacial surgery were from age-group 17 to 22. About 64% of age group 17 to 22 knew that a dentist can do maxillofacial surgery. About 25% of age group 23 to 29 were aware that a dentist can do maxillofacial surgery.(Table 3)

About 62% of participants were aware that the dental related surgical procedures were done under anaesthesia. In the sample who knew that dental related surgical procedures were done under anaesthesia , about 69% were from age group 17 to 22 and 23% were from age group 23 to 29 and 8% were from age group above 30. About 64% in age group 17 to 22 knew this.About 60% in age group 23 to 29 were aware of this.(Table 3)

Table 3–Participant's knowledge aboutprocedures and treatment that could be provided by the dentists.

Are you aware that your dentist can treat oral cancer	Age group 17-22	Age group 23-29	Age group above 30	Total
Answered yes	(57%)38	(20%)19	(14%)9	66
Answered no	32	6	1	39
Total	70	25	10	105
Percentage of answered yes in the specific group	54%	76%	90%	
Are you aware that a dentist can do maxillofacial surgery	Age group 17-22	Age group 23-29	Age group above 30	Total
Answered yes	(67%)45	(25%)17	(8%)5	67
Answered no	25	8	5	38
Total	70	25	10	105
Percentage of answered yes in the specific group	64%	68%	50%	
Are you aware that dental related surgical procedures done under anaesthesia	Age group 17-22	Age group 23-29	Age group above 30	Total
Answered yes	(69%)45	(23%)15	(8%)5	65
Answered no	25	10	5	40
Total	70	25	10	105
Percentage of answered yes in the specific group	64%	60%	50%	

About 16% of 105 participants had undergone maxillofacial surgery in their lifetime . Of the people who have undergone ,59% are from age group 17 to 22.This higher value might be due to the sample size bias favouring the first group . Only 14% in the age group of 17 to 22 had undergone maxillofacial surgery. About 16% in the age group of 23 to 29 had undergone the maxillofacial surgery, hence they be aware of this OMFS. About 30% in the age group of above 30 had undergone maxillofacial surgery.

The number has increased when it comes to the family members and friends. About 20% of 105 participants had family members or friends who had undergone maxillofacial surgery. Of the people who have such family or friend, about 57% are from age group 17 to 22 which would also fall under thebias.About 17% in age group 17-22 had such family or friend. About 28% in age group of 23 to 29 had family members of such category. But in the age group of above 30, the number has decreased to 20%, this may be due to the limited number of sample in the group.(Table 4).

Table 4– Percentage ofParticipants and their family members who have undergone Maxillofacial surgery in study population.

Have you ever undergone any maxillofacial surgery	Age group 17-22	Age group 23-29	Age group above 30	Total
Answered yes	(59%)10	(24%)4	(17%)3	17
Answered no	60	21	7	88
Total	70	25	10	105
Percentage of answered yes in the specific group	14%	16%	30%	
Has anyone in your family undergone maxillofacial surgery	**Age group 17-22**	**Age group 23-29**	**Age group above 30**	**Total**
Answered yes	(57%)12	(33%)7	(10%)2	21
Answered no	58	18	8	84
Total	70	25	10	105
Percentage of answered yes in the specific group	17%	28%	20%	

About 57% of total sample have known that the jaw related fractures are treated by maxillofacial surgeon. About 63% of total sample have known that cleft lip could be treated by dentist. About 66% of total sample have known that the maxillofacial surgeon could treat dental trauma. About 55% of total sample have known that the OMF surgeon could do Aesthetic jaw bone correction.(Table 5)

Table 5 – Percentage distribution of study population regarding the knowledge about the specific treatments and procedures in OMFS done by dentists and OMF surgeons.

Knowledge about OMFS	Age group 17-22 Answered yes	Age group 23-29 Answered yes	Age group above 30 Answered yes	Total Answered yes	Total answered no
Jaw related fractures are treated by maxillofacial surgeon	40 (30 answered no) (69% belonged to this group who answered yes)(57%of this group answered yes)	15 (10 answered no) (25% belonged to this group who answered yes)(60%of this group answered yes)	5 (5 answered no)(8% belonged to this group who answered yes) (50%of this group answered yes)	60(57%of total)	45
A Dentist can treat cleft lip	40 (24 answered no) (70% belonged to this group who answered yes)(66%of this group answered yes)	13 (12 answered no) (20% belonged to this group who answered yes)(52%of this group answered yes)	7 (3 answered no) (10% belonged to this group who answered yes) (70%of this group answered yes)	66(63%of total)	39
A maxillofacial surgeon can treat dental trauma	46 (22 answered no) (69% belonged to this group who answered yes)(59%of this group answered yes)	16 (9 answered no) (23% belonged to this group who answered yes)(64%of this group answered yes)	8 (4 answered no)(8% belonged to this group who answered yes) (60%of this group answered yes)	70(66%of total)	35
OMF surgeon can do aesthetic Jaw bone correction	40 (30 answered no) (69% belonged to this group who answered yes)(57%of this group answered yes)	15 (10 answered no) (26% belonged to this group who answered yes)(60%of this group answered yes)	3 (7 answered no)(5% belonged to this group who answered yes) (30%of this group answered yes)	58(55%of total)	47

Even though the knowledge percentage of general population sample in our study had shown increased results, the numbers are not denoting the actual knowledge of sample knowing the actual difference between the maxillofacial surgeon and the dentist. The sample might have understood that a dentist would do care dental problems, and maxillofacial surgeon to facial problems. According to

thenominalsuggestions,the sample might have answered the questions. The results were given in the table.

Discussion

Among the groups, even though the age group of 17 to 22 was greater in number than the others, the distribution was somewhat similar in each age group. About mostly 60% in all the age groups, were aware of the speciality. Most of the findings in this article would not surprise older and practising maxillofacial surgeons. It does bring home reality that OMFS speciality is not easily recognised by the public[5].In study done by Reddy et al[6], found that all study groups were not clear about the scope of the specialty and its capabilities. This may be true as the general population may know about the speciality but they are not aware of the scope of the speciality and what the speciality could do to them.There's not much a difference between each age groups in our study, and also there's not muchdifference between the results in each age groups .

Two limitationswithregardtoourquestionnairewere :itwasinEnglishwhich made it difficult for some of the participants , and also, the questionnaire required time andconcentration to complete,andit was difficult for the respondents due to their inability to know about the survey but we took sure amount of struggle in order to make the participants knew about the survey and the Surveyplanet website app had helped to reach therequired participants. As the strength of sample size was more in the age group of 17 to 22, the results are slightly biased towards this group than the other group, favouring the group 17 to 22. This may be slightly true as today's resources are readily available to the teens as most of the social media are the major source of information. The older generation might have heard this speciality from their friends or family members who have gone to the OMFS doctors or by personal experience being referred to the OMFS specialist by the generalphysicians[23].For which the general physicians should know more about the OMFS specialty. Apparently, some students and professionals are not aware of the wide surgical scope of the specialty. A majority of health-care professionals recognise OMFS, but some students and professionals are not aware of the wide surgical field of the specialty [20][21][22] .

The nominal suggestions of the speciality played a major part in distortion of results towards the higher knowledge among general population which is good in some manner but is not worth without the actual knowledge about the scope of the speciality .Although this does not mean that no effort should be made to inform the public about what OMF surgeons do, it does indicate that no name alone can ever be completely descriptive [18][19].

Oral and maxillofacial surgery initially started as a branch of surgical dentistry by dentists who had a special interest in surgery. They were then known as oral surgeons. In World War II, the specialty increased its remit to include maxillofacial trauma by a few dedicated units in the UK and the USA. Then over a period of time, they increased their scope to include facial deformity correction, pathology and so on to reach its current position. By this time the specialty was known as oral and maxillofacial surgery. In certain countries it is now mandatory to get both a medical and dental qualification before becoming a maxillofacial surgeon. Whether this dual qualification is needed to practice maxillofacial surgery or whether it is used as a "political" weapon to remove the tag of a "dentist" is still under debate. The dental and medical association hears this topic on a regular basis in nearly every conference.

In India, lately there has been a vast increase in the number of trainees in Oral and maxillofacial surgery and this has improved the visibility of the specialty. This is mainly due to the increase in the number of college seats available at a postgraduate level lately. This study shows that it is very important to promote the specialty among the general population and also in the media. Having a simpler name could be the first step in making the specialty well known. Otolaryngologists have now changed their name to ENT surgeons, making it easier to pronounce and remember[13][3][16][17].

Although OMFS is a branch of dentistry, it is one of the specialties that bridges to the medical community so closely. Current trend shows that a full medical degree is not that necessary for OMFS specialists to practice with competency. OMFS specialists are qualified to treat not only dento-alveolar surgeries, but also a full scope of jaws and facial surgeries including facial fractures, congenital facial deformities, temporo-mandibular joint (TMJ) disorders, pathologies related to the jaws, salivary gland diseases, facial reconstructions with extra-oral bone or soft tissue harvesting. With adequate training or, in some situations, collaborating with other specialties, the scope could be expanded to cranial-facial reconstructions, oncology and reconstructions using local or distant microvascular free flaps. Although the specialty involves in the treatment of a lot of important conditions or diseases, it is disappointed to see the lack of awareness from the general public. It was reported that there were only 11.5 % who had ever heard of and knew what OMFS was according to an older study.Although this is the case, in general, there is an increasing trend towards the recognition of Oral and Maxillofacial Surgery as a specialised branch for the treatment of many conditions as compared to the past[13][14][15][16] .

According to the older studies, OMFS was introduced to a majority of people (65%) by a friend or a family member. This indicates that most of the knowledge was by personal experiences of people around. There was almost no public image about this specialty. The government or tertiary institute could

publicise this field by media like TV, radios or newspapers through interviews or in terms of case study. The local association should also take a leading role to arouse the public awareness regarding our specialty, either by organising public talks or distributing leaflets / booklets / magazines regularly. In our study, the awareness has increased as the information about the speciality are readily available through Internet.There are 58% of interviewers answered yes to the question that OMFS belongs to the field dentistry. It is not surprising as the name OMFS itself indicated that is something about the oral cavity, thus dentistry.

Parnes [7] stated that the governing bodies of the American Association of Oral and Maxillofacial Surgery formed a task force to discuss a possible name change for the specialty. Any change from the current name was rejected at that time. One of the concerns over changing the name was that another specialty of dentistry or medicine might adopt the abandoned name.

Laskin et al. [8] evaluated the knowledge of 12 different specialties to determine whether such unfamiliarity is true only for OMFS, or whether it occurs with other specialties also. The result of their study shows that every effort should be made to inform the public about what OMF surgeons do.

Clinical entities like facial asymmetries are a great challenge to any operating surgeon. Orthognathic surgical procedures may be needed in correcting such dentofacial deformities. This requires a multidisciplinary approach that includes orthodontists, periodontists, and prosthodontists. An OMFS would live up to the realistic expectations of the patient by giving a desired aesthetic look, simultaneously securing the occlusion. Of great concern is the undeniable fact that most of the general public (35%) are unaware of this fact. In this regard, 25% of the general public and 33% of the medical professionals preferred plastic surgeons. Similar findings were observed by Ifeacho et al [3][12].

A cross-sectional study done by Rastogi et al. [9] in Manipal Teaching Hospital, showed that medical professionals would like to consult OMFS for fracture of mandible, maxilla and zygoma. Also, OMFS scored an absolute majority in clinical situations like dental implant and removal of wisdom tooth and around 76 % for mandibular reconstruction.

The present study, nevertheless, has shed light on what the perception is of the domain of the OMFSamongthe general public. Procedural awareness mentioned within the questionnaire was significantly still weak. The Association of Oral and Maxillofacial Surgeons should take a leading role to arouse public awareness concerning the specialty, by audit, publications, or organising public talks or camps regularly. Educational institutions are the leading lights to promote awareness. This would have an

effect on the dynamics of the entire system, not only to the patients or the public, but also to the doctors who provide the treatment.The Association of Oral and Maxillofacial Surgeons of India (AOMSI) observe February 13th as the day of OMFS to commemorate its first meeting held on this date in 1969. The objective of this initiative is to bring about increased awareness in the general public about the advances the specialty has made. This we feel needs to be followed and expanded.

Greater progress needs to be made in the education of medical and dental students as well as the general public if the specialty of OMFS is to be practiced to its full potential [10, 11].

Conclusion

In summary, there is a very low awareness in OMFS to the general public in terms of its scope of service, the provision of service and training by the government and institutes. It is very discouraging to learn that most of the people do not really knowOMFSas they may miss the chance to be treated or to be trained. There is no doubt that the specialty deserves a better public awareness. The stress should be put on three areas, namely the public image of who OMF surgeons are, awareness of the treatment OMF surgeons could provide, the awareness of the details of training pathways and opportunities. The objectives are to let more people know who they should seek help from and provide open opportunities for people to be trained.

The surprising fact in this matter was our colleaguesin Otorhinolaryngology (ENT) and plastic surgery are well known than OMFS. The worrying aspect is that the plastic surgeons would not be found easily in the city but they are well-known. On the other hand, OMFS specialists could be found in the city hospitals but they are not known to exist to the general populations. This survey was performed only in the Northern region of Chennai areas, and therefore the results may not be applicable elsewhere. Regional variations exist, and surgeons are responsible for educating their own community and referral circles about the scope of their practice, which will depend on the training, experience and areas of interest. It is clear that greater progress needs to be made in the education of medical and dental students, as well as the general public, if the specialty of OMFS is to be practiced to its full potential[10][11].

Saveetha University, Chennai, India

Abstract

Introduction: Gingival recession, either localized or generalized, may be associated with one or more surfaces, resulting in attachment loss and root exposure, which can in turn result to clinical issues such as root surface hypersensitivity, root caries, cervical root abrasions, difficult plaque control, reduced cosmetic appeal and aesthetic concern. The aim of this study is to assess knowledge of various root coverage techniques and their implementation among periodontists in Chennai.

Materials and Methods: We conducted an online survey amongst Periodontists working in Chennai, Tamil Nadu to which 65 Periodontists responded. 29 were male participants and 36 were female. The questionnaire consisted of 12 questions, 11 of them giving the possibility of multiple choices of answers and one question being open ended for the participant to fill in an appropriate response. The demographic profile, interests, frequency of performing and satisfaction in root coverage techniques were assessed.

Results: Periodontists well versed in literature and advanced root coverage techniques were found to perform root coverage procedures more frequently than those who were not.

Conclusion: This study concludes that less experienced Periodontists perform root coverage techniques (both conventional and advanced) more frequently and that most Periodontists agree that connective tissue graft proves more effective amongst other techniques listed.

Keywords: *Recession, root coverage techniques, connective tissue graft*

Introduction

Over the years, a large number of surgical techniques have been introduced to correct labial, gingival recession defects. Aesthetic concerns are the most common reason to perform these procedures. Clinical studies have evaluated many of the techniques.In subjects who exercise oral home care and have regular dental check-ups, gingival recession was the predominant periodontal finding before 40 years [1]. And sites with recession seem to be susceptible for additional apical displacement of the gingival margin [2]. Several procedures have been proposed for the treatment of buccal gingival recessions and three systematic reviews have assessed their efficacy by evaluating some quantitative aspects of treatment outcomes. The first review [3] included the coronally advanced flap, the lateral positioned flap, the free gingival graft, the connective tissue graft, guided tissue regeneration (GTR) with resorbable and non-resorbable membranes. Combining the results of six clinical trials [4-9], a significant advantage of connective tissue grafts over GTR was demonstrated by meta-analysis in terms of reducing recession [3]. Overall it was concluded that all procedures were effective in reducing gingival recessions, with a slight advantage of connective tissue graft over- GTR. The second review [10], published after the completion of the present survey, compared connective tissue graft with GTR and came to the same conclusions. An additional review [11]also evaluated data from currently available studies on root coverage procedures to repair gingival recession. GTR-based root coverage was found to successfully repair gingival recession defects, but conventional mucogingival surgery resulted in statistically better root coverage and width of keratinized gingival.

Patient’s desire to improve esthetics is often mentioned as a major motive for intervention. Yet, in reviewing the pertinent literature, it can be noted that esthetic aspects have not been analyzed in comparative studies and could therefore not be taken into consideration for the above-mentioned conclusions. Other justifications include dental hypersensitivity, problems in controlling plaque formation due to an unfavorable contour of the gingival margin, and the expectation that this will prevent further progression. While studies have documented favorable clinical results and their relative stability over time, treatments have not been compared to no therapy or a sham intervention, and thus the evidence for an advantage of surgical interventions in controlling these factors are limited [12].

Little is known about the knowledge transfer from research to clinical practice. It is essential to learn about possible gaps between research and practice in order to adapt to continuing education and to ensure that researchers include questions that are relevant to practicing dentists. The purpose of this study was therefore to evaluate the views, knowledge and preferences of a large sample of practicing dentists in Periodontology, focusing specifically on the treatment of gingival recessions, and to compare the findings with the current evidence available in the dental literature.

Materials and Methodology

We conducted an online survey amongst 80 Periodontists [13,14] working in educational institutions as well as in private clinics in Chennai, Tamil Nadu to which 65 Periodontists responded. 29 were male participants and 36 were female. The questionnaire consisted of 12 questions, 11 of them giving the possibility of multiple choices of answers and one question being open ended for the participant to fill in an appropriate response. The demographic profile, interests, frequency of performing and satisfaction in root coverage techniques were assessed.

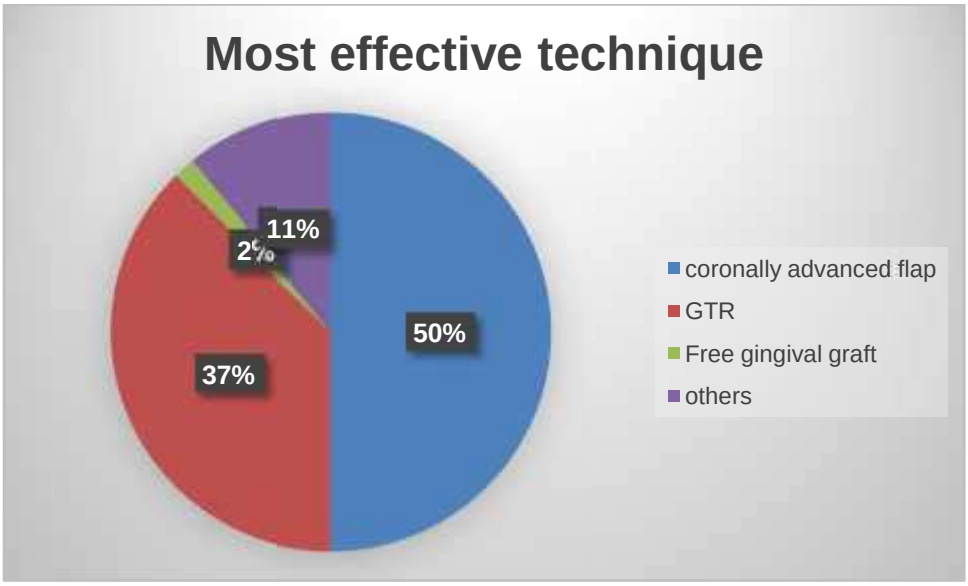
Results

Most of the participants predominantly belonged to the age group of 30-50 years (34 in no.). In terms of years of practice, newer private practitioners with 0-5 years of experience made up 52% (34 in no.) of the sample population of periodontists and 35% (23 in no.) with 6-10 years of experience.

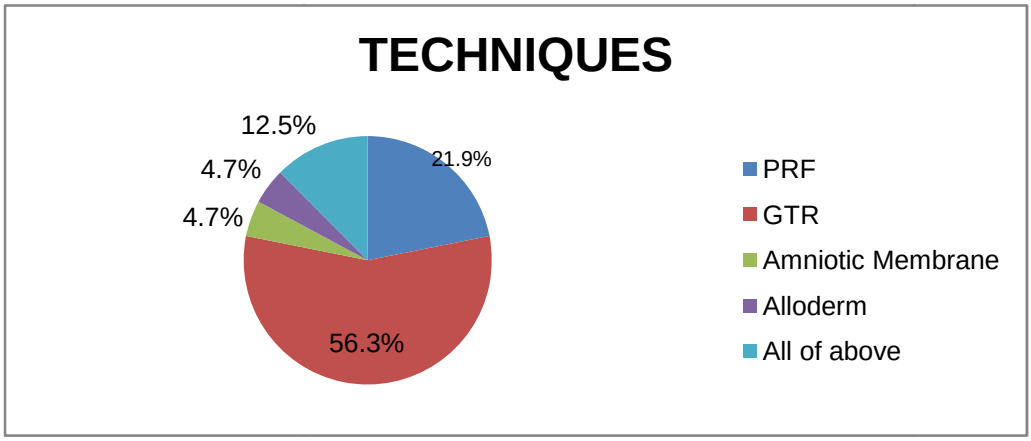
When asked about the clinical situations where they would perform root coverage techniques, dentinal hypersensitivity (33%) (21 in no.) and aesthetics (33%) (21 in no.) were the most common responses.

Newer root coverage techniques such Vestibular Incision Subperiosteal Tunnel Access (VISTA) and root coverage using autologous fibroblasts cell culture were some of the responses to the other advanced techniques the participants have performed so far (Graph2).

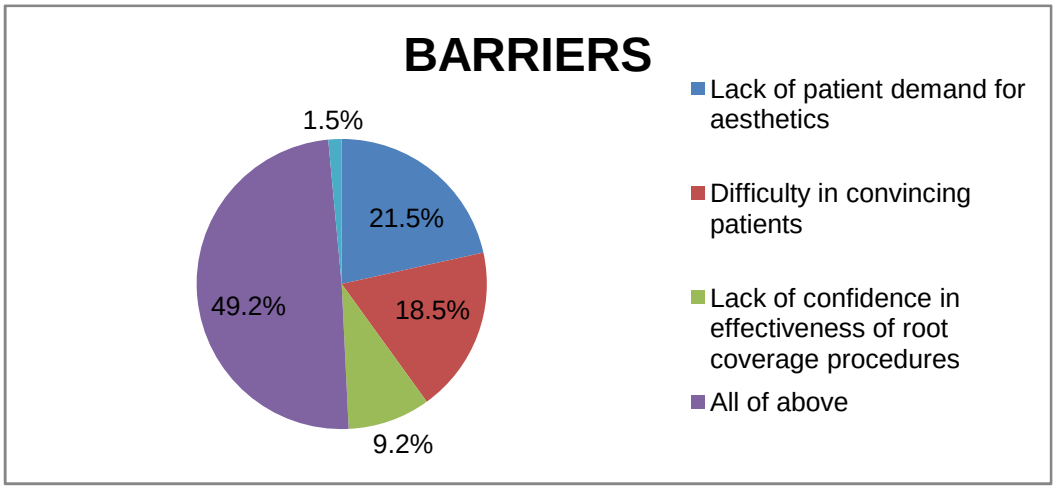
Graph1: Most effective root coverage procedure



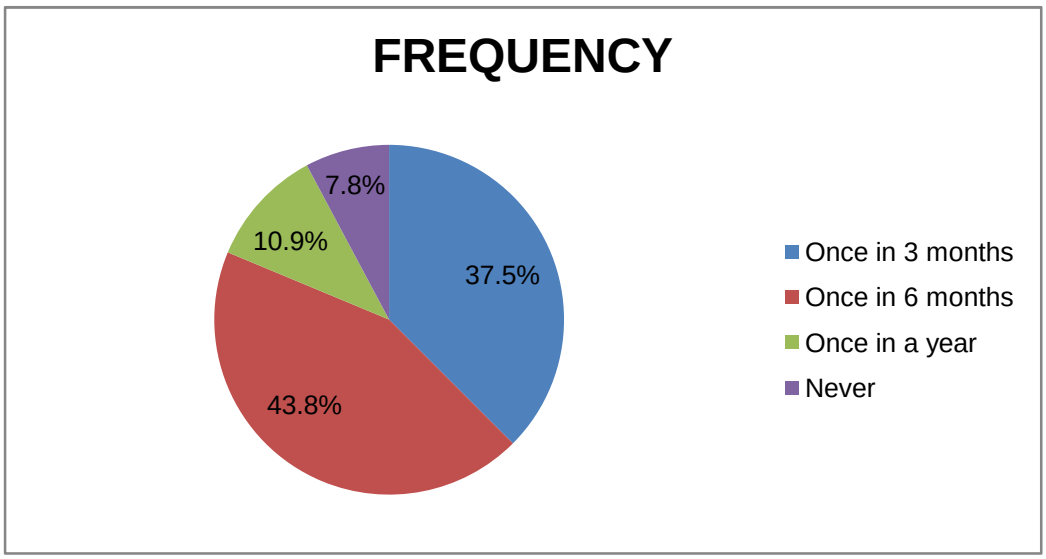
Graph 2: Newer advanced root coverage technique implemented in private practice.



Graph 3: Barriers faced in performing root coverage techniques



Graph 4: Frequency of performing root coverage techniques



Discussion

In our survey Periodontists of the age group 30-40 years participated predominantly and they comprised of44percentileof the total while periodontists of the age group 50 years and above were only 3 percentile of the 65 participants.

From the results of the survey, we can infer that periodontists who are 0-5 years into clinical practice perform root coverage procedures more frequently and are well aware of the advanced procedures for recession. This may be attributed to their recent completion of post graduation and performing root coverage techniques in their post graduate set up. The survey showed majority of the periodontists opted for connective tissue graft for root coverage over other mentioned techniques [Graph 1]. This is in concordance with the studies by Jepson and Rosetti.E who concluded that connective tissue graft was a more effective method of root coverage techniques. [4, 8]

Among the barriers faced in performing root coverage procedures like non conscious about esthetics, inability in convincing patients, lack of confidence in effectiveness of root coverage procedures most of the periodontists opted for the all of the above option which suggests that the correlation between frequency of performing root coverage techniques and barriers faced is inversely proportional [graph 3]. About 43.8% participants did root coverage procedure once in 6 months, and 37.5% did once in 3 months [graph 4].

In a study by Zaher C A [12] aesthetic concerns were the predominant indications for root coverage procedures. They suggested further research should therefore include aesthetic aspects as primary clinical outcome variables for root coverage procedures [15]. One of the most common esthetic concerns associated with the periodontal tissue is gingival recession [16]. Esthetics was suggested as a major indication of root coverage procedures by general dentists, but hypersensitivity was the major concern for periodontists for performing root coverage procedures. Patients have, recently, become more conscious of dental esthetics and accordingly have been demanding precision treatment of their exposed root surfaces [17].

The major limitations of this study include the smaller sample size, and since this is a questionnaire study it is highly subjective and depends on Individual responses.

Conclusion

In this questionnaire study we conclude thatConnective tissue graft along with GTR technique was the most commonly preferred root coverage technique [18]. Approximately half of the participants performed root coverage procedures once in 6 months and followed by many of them who performed at least once in 3 months. Esthetic unawareness, difficulty in convincing patients and Lack of confidence were the proposed reasons for not performing root coverage techniques by the participants.

Awareness of Varicose Veins among Dental Students – Pilot Study

Nathasha A/P Sivakumar[1], Brundha.M.P[2], Dhanalakshmi Ravikumar[3]

Graduate Student[1], Senior Lecturer[2], Department of General Pathology,

Senior Lecturer[3], Department of Pedodontics and Preventive Dentistry,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction: In the modern living and working conditions, dentists are working in an environment with more effort and holding of fixed positions for longer duration of time. So the present study was undertaken to evaluate their knowledge about varicose veins to give knowledge to undergraduate dental students.

Materials and Methods: 50 dental students were selected on this study. The questionnaires were distributed among the dental students aging 20-26 years old. Informations were collected via a structured proforma, which includes demographic variables. The students were asked to choose only one answer for each question whuch they think would be the most appropriate answer. All data collected was compiled to do statistival analysis.

Results: This survey shows that 70% of the students said they were aware of varicose veins from other sources while 16% of them were alerted by their friends and 8% of them by work colleagues.

Conclusion: With the light of available evidence this study concludes that there is a need to create awareness among undergraduate sental students regarding the complication of varicose veins. This may help the clinician to avoid complications in their general practice.

Key Words: *Varicose veins, Non return valves, deoxygenated blood, pigmentation, lower limb veins.*

Introduction

Chronic venous disease is a common condition presented to the general physicians worldwide. Varicose veins , is a commonly reported venous disease. Varicose veins are tortuous, widened veins in the subcutaneous tissues of the legs and are often easily visible. Their valves are usually incompetent so they might have reflux of blood occurs, and this resulting venous hypertension can cause symptoms[1]. Varicose veins are widely seen as medically unimportant and deserving low priority for treatment. They are common, affecting nearly a third of adults in Western societies, and few people with varicose veins are ever harmed by them. However, this can cause concern and distress on a large scale, most of which can be dealt with by good explanation and reassurance, or by a variety of treatments which are evolving rapidly at present time. Patients can now be referred for more precise assessment and a greater range of therapeutic options than ever before [2].

Varicose Veins is common disease which affects one third of the population of which prevalence is observed in the Western Europe and the United States. A study revealed that, from the affected population, there is around 1-73% of females (especially during pregnancy) exposed to this disease and on an average 2-56% of males. Thus, we may conclude that women are more likely to be affected than men[3]. Varicose Veins or Venous Insufficiency is a disease which involves enlargement and gnarling of the Veins usually of legs. In this disorder, there is reflux flow of blood through the valves of legs, hence instability in circulation of blood.

The risk factors of includes age, hereditary, pregnancy, obesity, occupation which involves prolonged hours of standing, Diet, Type of physical activity, Excess use of hormones, etc[4]. These factors are not clearly known yet. Symptoms related to Varicose veins may not be observed in case of some affected population. If seen the symptoms of this disease at initial stages include severe pain, swelling, itching, heavy legs, and lipodermatosclerosis (skin thickening). If left untreated, the further complications lead to bleeding veins, eczema, skin pigmentation or discoloration. Later it can cause venous ulcers, and hence complete vein incompetence. Diagnosis of the varicose veins disease is done using the duplex scan method of investigation

Varicose vein is a dilated, elongated, tortuous and it is often palpable superficial venous system of the body and especially in the lower extremities. Other commoner areas are the umbilicus (Capus medusa), scrotum/ vulva (varicocele) and rectum (haemorrhoids) [5]. They can be found in the upper extremities along the distributions of the cephalic and basilica veins, though rarely.

Visible varicose veins in the lower extremities are estimated to affect at least a third of the population and 28.6% of people with varicose veins progressed to develop serious venous diseases. Also 3-6% of people with varicose veins in their life time progress to develop venous ulcers [6].

In the lower extremities, there are two main superficial veins, namely the great saphenous vein (GSV) and the small saphenous vein (SSV).The proportion of limbs whose GSV and SSV affected with varicosity ranges from 25-35%. Isolated SSV varicosity occurs in about 14% of limbs [7].

The incidence of chronic venous insufficiency and related varicose veins is variable and fluctuates according to factors such as age, sex, and geographical locations. Extrinsic environmental factors and intrinsic pathological conditions contribute to the disease, including family history, obesity, older age, pregnancy and female gender [8]. The clinical features and Doppler ultrasonography are currently used in making preoperative diagnosis Current treatment procedures are divided into conservative and surgical. The conservative methods are leg elevation, exercise, bandaging and massage, generally referred to as Bisgaard regime. The surgical methods are high ligation, multiple ligation and stripping, endovenous laser ablation (EVA), sclerotherapy and ambulatory phlebectomy [9]. In Nigeria, a developing country, the newer techniques are currently not available. Assessing the outcome of treatment requires well defined measures and this is particularly difficult in varicose vein surgery

Varicose veins do occur when there are incompetent perforators, incompetent valves of the superficial veins, deep vein thrombosis, atriovenous fistula (AVF) and pelvic mass(es) like pregnancy, tumours obstructing blood flow towards the heart. Other causes include family history and idiopathic[10].

A study on large population of UK has shown age adjusted prevalences of 40% in men and 32% in women, although women more often present for treatment. The age of onset varies; some people develop varicose veins in their teenage years, but prevalence rises with age. Varicose veins often appear in first pregnancy, and further pregnancies can make them worse. A family history is common but people should be reassured that having close relatives with severe symptoms from varicose veins does not confer any great likelihood that they will have similar problems[12].

Varicose veins can cause a variety of symptoms of discomfort in the legs, but it is important to try to differentiate these from the many other reasons for leg pains. The Edinburgh vein study

found that the symptoms significantly associated with varicose vein were itching, heaviness, and aching, but the relation of these with varicose veins was inconsistent, particularly in men [13]. Traditional pointers to symptoms being caused by varicose veins include worsening of symptoms after prolonged standing or walking and towards the end of the day, relieving symptoms by elevating the legs or wearing support hosiery, and tenderness over the veins [14].

There are several factors which can be related to the development of varicose veins. That includes, age, gender, family history, obesity and most importantly the standing occupation[15].The reverse flow of blood in veins is prevented by one-way valves. The veins starts leaking, leading to the stagnation of th deoxygenated blood in the leg veins [16].

Extensive evaluation of the venous disease and the ligation of the site deep to the superficial reflux are one of the way of preventing the recurrence. On recurrence, Doppler sound is accurate in deep venous assessment and in demonstrating the leakage of the veins [17]. Few studies have revealed that, up to 15% of men and 25% of women have visible varicose veins. One should know early symptoms of this disease so as to avoid complications which can be dangerous as visible dilated veins over the thighs and legs [18].

It is also a very common disorder usually neglected by patients due to lack of pain in the initial stages of the disease. Varicose veins said to be responsible for a variety of symptoms such as swelling, aching, cramps and tingles [19].

The early recurrence is found in a few cases due to incorrect diagnosis. Late recurrence, in the majority of cases, is due to incorrect surgery or the overlooking of gastrocnemius vein incompetence. In some cases deep reflux, soleal arch compression or left iliac vein compression was found to be the possible causes of recurrence [20].

The condition of varicose veins is significantly common in the population of Tamil Nadu, especially in older individuals and women. Individuals whose occupations involve standing for long hours are prone to varicose veins. A large portion of affected population failed to undergo treatment for varicose veins. The awareness about the treatments available for varicose veins may encourage the affected population to undergo the required treatment [21].

In the modern living and working conditions, dentists are working in an environment with more effort and holding of fixed positions for longer duration of time. So the present study was undertaken to evaluate their knowledge about varicose veins to give knowledge to undergraduate dental students.

Material and Methods

- **Ethical Approval**

The present cross-sectional study was carried out after obtaining Ethical approval from the Institutional review board of Saveetha Dental College.

- **Study Design**

The survey was conducted in a single dental school in Chennai. This was one of the first study to assess the knowledge of undergraduate about varicose veins. Since it was easy to recruit the study population from a single dental school, purposive sampling technique was chosen. A sample of 50 undergraduate students in a Saveetha Dental School, Chennai, India was included in the study.

The study was undertaken in two stages stage 1 and Stage 2. Stage 1 comprised formulating, designing, and validating the questionnaire, whereas Stage 2 tested the validated questionnaire among 50 undergraduate dental students.

- **Stage 1 (Designing and Validation of Questionnaire)**

A standardized self-constructed questionnaire was formulated by two investigators (NS, DR,). Both the investigators (NS, DR,) independently formulated the questionnaire, and after a consensus, they arrived at a final list of 15 questions. The questionnaire was based on the source of knowledge, Etiology, signs and symptoms and its preventive measures. Initially, content validation of the questionnaire was performed by circulating the questionnaire to 10 qualified General dentists. A panel discussion was conducted among 10 qualified General dentists, and they had rated the questionnaire using content validity ratio [14-16]. There was a good agreement between the investigators, with a rating of >0.7. Finally, the questionnaire was distributed to 10 random General dentists for face validation, and it was evaluated using 5-point Likert scale.

- **Stage 2 (Testing of Validated Questionnaire)**

After the content and face validation, the questionnaire was distributed to 50 undergraduate students to complete the questionnaire. Distribution and collection of the questionnaire were done by one Graduate dentists (NS).

- **Statistical Analysis**

Data were collected and entered into SPSS software version (SPSS Inc., Chicago, IL, USA) 20.0 for percentages.

Results

This survey shows that 70% of the dental students said they were aware of varicose veins from other sources while 16% of them were alerted by their friends. 8% of the dental students were aware of it by work colleagues. (Table 1). Among the 50 students, 50% of them were saying that standing for a long period of time is the most common cause of varicose veins. Meanwhile, 25% of the dental students were told that the disease might occur because of obesity. 12% of them were told that aging might be the most common cause of this disease.(Figure 2). Awareness regarding the signs and symptoms of varicose veins 52% of the dental students were aware that visible bluish-purple cluster in the legs is the most common clinical feature seen in varicose veins. Followed by 16% of them stated that varicose veins might be seen as swelling of ankle and feet. 10% of the dental students were telling that aching and itching in the legs is the signs. (Table 3). In awareness about the preventive measures, out of the 50 students, 56% of the students say that it can prevented by avoiding standing for an extended period of time. 26% of them said that it can be prevented by exercising to improve the strength of the leg, while 14% of them said that losing weight or maintaining a healthy wait could be the best preventive measure.(Table 4). Among the 50 students, 58% of them were not aware of the treatment for varicose veins. While 18% of them were saying it would be Sclerotherapy and 14% says that it can be corrected by surgery.(Figure 5). Table 6 and Figure 7 depicts the various treatment and preventive measures available for varicose veins and their awareness among students.

Table 1: Knowledge about varicose veins among dental students

STATEMENT	YES	NO
NUM OF STUDENTS	48	2
PERCENTAGE (%)	96	4

- Among 50 dental students, 96% of them were aware of varicose veins.

Table 2: Source of knowledge

STATEMENT	NUM OF STUDENTS	PERCENTAGE(%)
Friend	8	16
Family member	1	2
Work collegue	4	8
Patient	2	4
Others	35	70

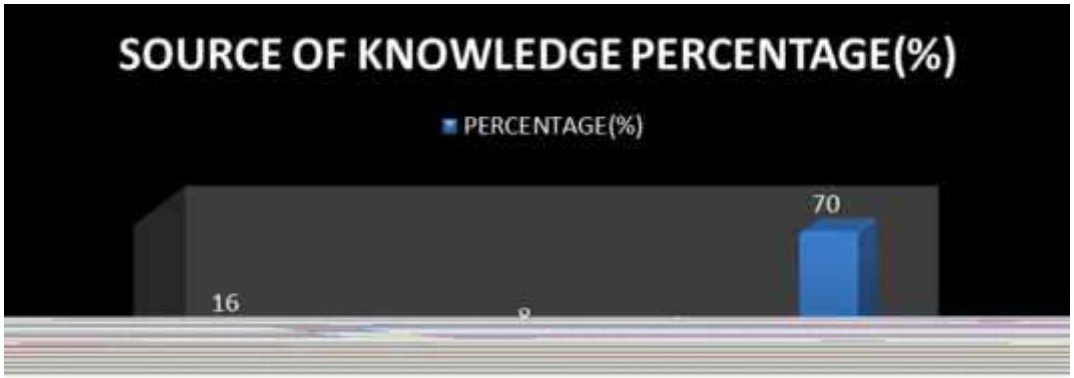

Figure 2: Source of knowledge

- The source of knowledge about varicose veins was 70% from others, according to the dental students

Table 3: Awareness about the causes

STATEMENT	NUM OF STUDENTS	PERCENTAGE (%)
Hereditary	2	4
Aging	6	12
Standing for long period of time	25	50
Obesity	13	25
Leg injury	1	2
Don’t know	3	6

- Among 50 dental students, 50% of them were aware that standing for a long period of time was the common cause for varicose veins

Table 4: Most common signs and symptoms of varicose veins

STATEMEMT	NUM OF STUDENTS	PERCENTAGE (%)
Aching and itching in legs	5	10
Discomfort	3	6
Heaviness	2	4
Swelling of ankle and feet	8	16
Brown skin discoloration in the area around the varicose veins	1	2
Visible bluish-purple clusters in the legs	26	52
Ulcers in the area around the varicose vein problem	3	6
Don't know	2	4

- 52% of the dental students, told that visible bluish cluster in the legs are the most common cause of varicose veins.

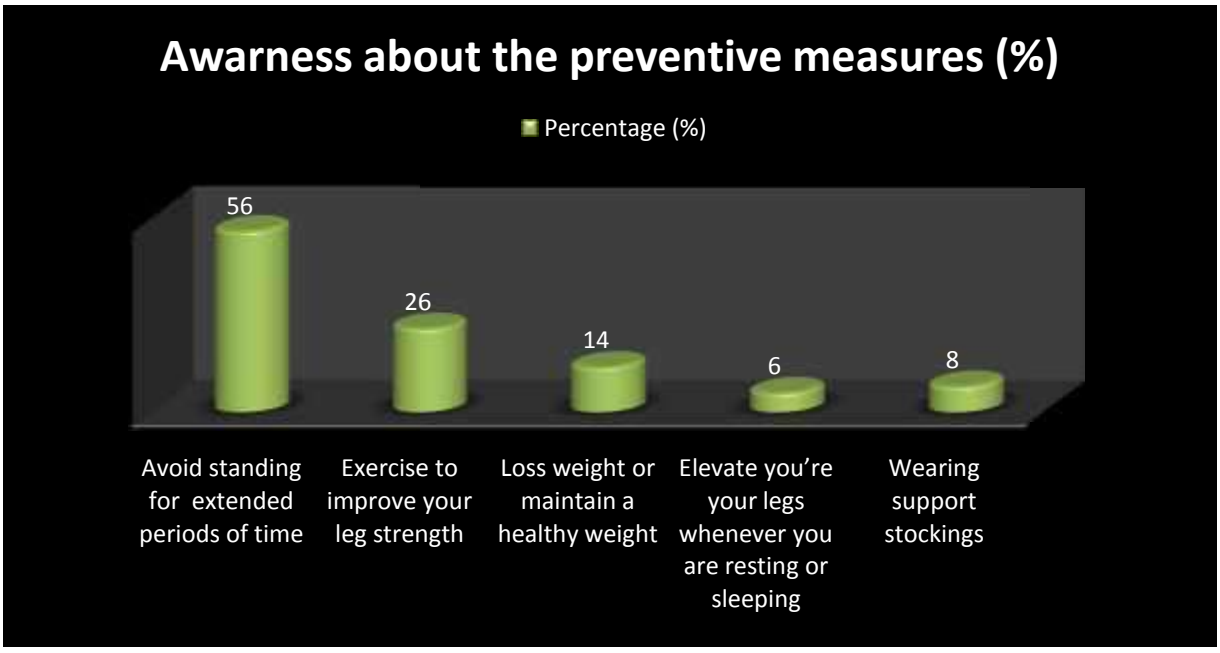

Figure 5: Awareness about the preventive measures

- Among 50 of the dental students, 56% of them are saying that avoid standing for a extended periods of time would be the best preventive measure for varicose veins.

Table 6: Awareness about the Treatment measures

Statement	Num of students	Percentage (%)
Surgery	7	14
Endovenous therapy	5	10
Sclerotherapy	9	18
Don't know	29	58

- 58% out of the 50 dental students don't know about the common treatment of varicose veins

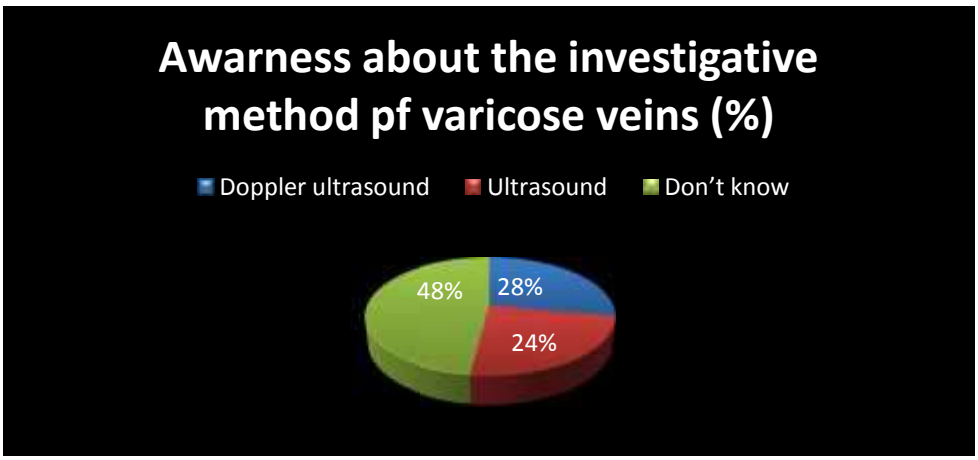

Figure 7: Awareness about the preventive measures

- Among 50 of the dental students, 48% of them were telling that Doppler ultrasound was the common method to identify varicose veins nowadays.

Discussion

This is one of the first study to exclusively evaluate the knowledge on varicose veins in undergraduate dental students. In the modern living and working conditions, dentist"s are working in an environment with more effort and holding of fixed positions for longer duration of time. So the present study was undertaken to evaluate their knowledge about varicose veins to incultate knowledge on them.

The questionnaire used in this research had been validated by content and face validation at the beginning of the study, based on the validation technique explained previously. The aim of this validation process was to gain the experts opinion and to modify the questionnaire in ease of understanding.

Of all the 50 students, 94% of them were aware of the causes of varicose veins, while 6% of them were not. A similar kind of study was done among staff nurse in Mangalore by Venisha et al and the author had concluded 61% of staff nurse had adequate knowledge about causes of varicose veins. A study done by A.W Willie et al has proved that the dentist are more likely to develop neurocirculated diseases such as varicose veins and this is considered as one of the occupational hazards of dentistry.

Among 50 students, 48 students were aware of the signs and symptoms of varicose veins while 2 students were ignorant about the signs and symptoms. Questions regarding the preventive measures 56% of students stated that avoiding of standing for a long period of time can be the best preventive measure. Questions regarding the treatment options, most of the undergraduate (58%) were not aware of the common treatment modality for varicose veins. Finally questions regarding the investigative methods for varicose veins 48%of undergraduates were aware about the investigative measures such as Doppler ultrasound.

Based on the results of the present study. It is clearly evident, that, knowledge and the information regarding the etiology, preventive measures, investigations, and treatment options of varicose veins are not sufficient among undergraduate dental students

Conclusion

With the light of available evidence this study concludes that there is a need to create awareness among undergraduate dental students regarding the complication of varicose veins. This may help the clinician to avoid complications in their general practise. Because even in this modern era, varicose veins has been the major problem seen in the dentists. So it is beneficial and important for every dental students to have knowledge on varicose veins.

Awareness on Contraception and STDs among General Population

Prema Sivakumar[1], M.P Brundha[2], Subash Sharma[3]
Graduate student[1],Head[2], Department of General Pathology,Reader[3],Department of Conservative Dentistry and Endodontics.
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: In the present day world, awareness and practice on contraception is very important. In a developing country like ours, it's of paramount importance due to the exponential population increase. In the Indian society, even amongst the educated population, contraception and sexually transmitted diseases are never discussed openly and are considered taboo. Birth control, also known as contraception and fertility control, are methods or devices used to prevent pregnancy. Planning, provision and use of birth control is called family planning. Birth control methods have been used since ancient times, but effective and safe methods only became available in the 20th century. Apart from taboos, people also believe in various traditional practices which may not be effective at all. The aim of this study is to assess the awareness and knowledge of contraceptives and sexually transmitted diseases amongst the general population.

Materials and Method: The sample size of the study is 55, with a random mix of males and females (30-M, 25- F) in a varied range of ages (25-65)

Conclusion: From the study it can be concluded that the overall awareness about contraception and STDs is 57%.

Result: The overall percentage of people who believe in contraception was 78% and the percentage of overall correct answers, which is an insight into the awareness level, was 57%. The awareness levels of males (57%) and females (58%) were almost the same.

Key Words*: Contraception, Awareness, Sexually transmitted disease, IUDs, oral contraception*

Introduction

With the second most populous country in the world, contraceptive knowledge, practice and proper implementation are essential for the improvement of health of existing population and a balance of the available resources and ultimately population stabilization. Family planning is estimated to have brought down maternal deaths by 25% and child deaths by 20%. [1] In this modern age, though people may possess half-baked knowledge about contraceptives, proper implementation and awareness is lacking. The choice of contraceptives has increased manifold over years, with the methods varying in their degree of effectiveness or convenience for the user. Many women have not yet identified the type of contraception that's most effective for their lifestyle and meets their personal requirements. [2] Studies indicate that the total fertility rate of a nation is inversely related to the prevalence rate of contraceptive use. [3]So this study was aimed at gauging the awareness of the general public and also kindling in them the need to be aware of the various methods.

Materials and Method

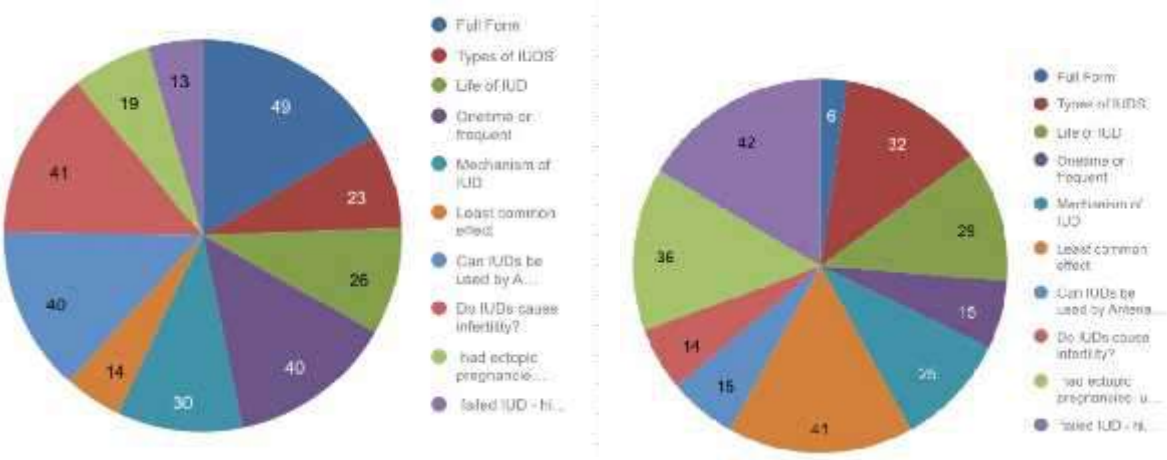
This study was a questionnaire based study conducted among 55 individuals. It had a group of basic questions (Age, sex, education) , and groups of questions each about the various types of contraception (IUDs, hormonal, barrier, emergency contraception, permanent contraception) followed by a final set of questions about sexually transmitted diseases. While designing the questionnaire, some very common myths and beliefs related to contraception were included. The questions were mostly of a multiple choice type (with some questions having a possibility of more than one right option) and a few open ended questions where the person would fill in based on whatever they're aware about from their pre-existing knowledge. The questions were intentionally made so as to test only the awareness of the methods and STDs and did not delve into any personal details, due to the high cloud of stigma surrounding this topic. Usually surveys like these are circulated only amongst women, but in this study the questionnaire was circulated online via email, to both males and females of varying ages (25-65) because contraception isn't for females alone, and awareness of the same is a pre-requisite for a responsible society. Also, the questionnaire was circulated only amongst educated people since the questions were solely awareness based. After collection of the data, it was tabulated and analyzed statistically.

Results

The questionnaire was split into different sections and analyzed, with graphs made wherever deemed necessary. The overall percentage of people who believe in contraception was 78% and the percentage of overall correct answers, which is an insight into the awareness level, was 57%. The awareness levels of males (57%) and females (58%) were almost the same.

A. IUDs

The average awareness percentage was found to be 54 %(Refer Fig. 1)



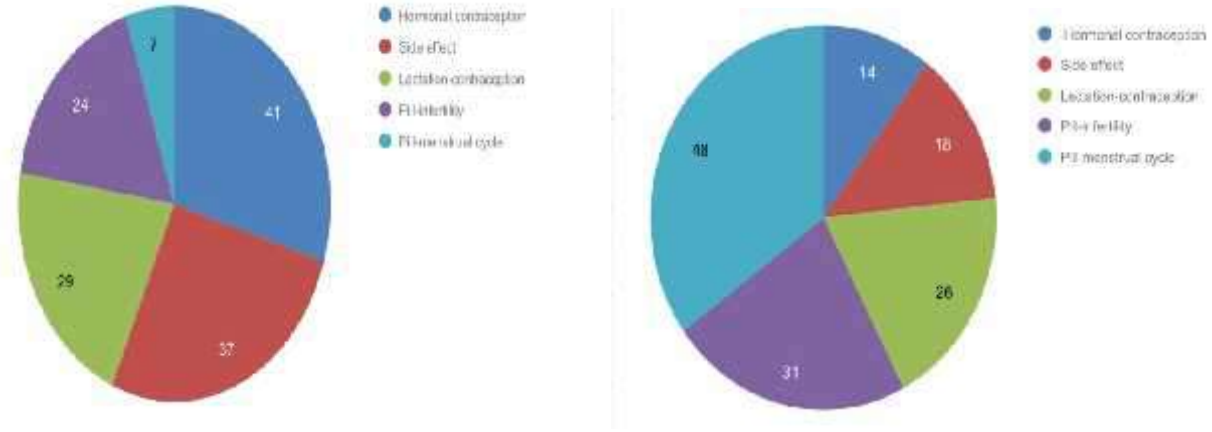
Aware Unaware

Figure 1: Awareness on IUDs:

1. Full form 2.types of IUDs with options 3. Length of using an IUD 4. How often it has to be changed 5. Mechanism of working of IUDs are all except (with option) 6. Least common side effect of IUDs (with options) 7. Can IUDs be used by ante-natal women 8. Do they cause infertility 9. Can it be used by those who have had ectopic pregnancies 10. Does a failed IUD increase the risk of ectopic pregnancies.

B. Oral Contraception

The Average awareness percentage was found to be 50.2% (Refer fig 2)



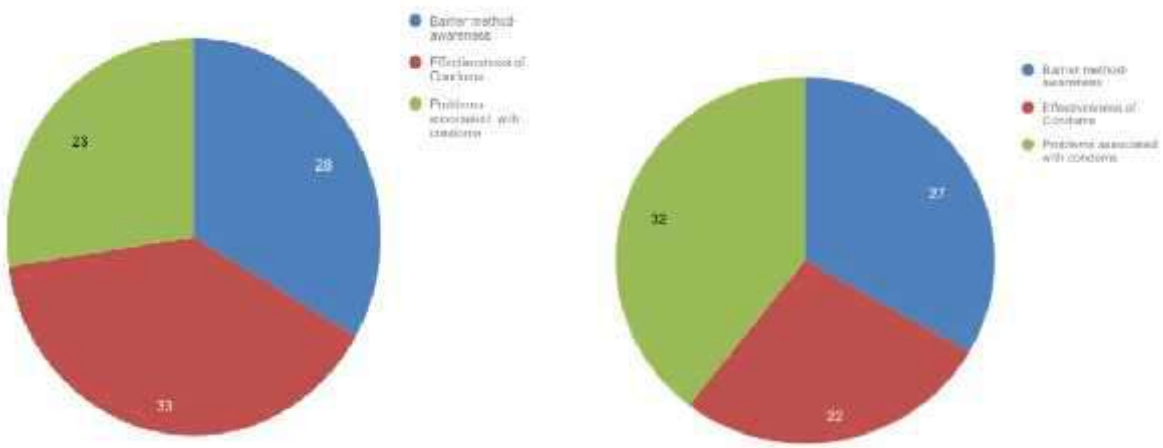
Aware Unaware

Figure 2: Awareness on methods of Oral contraception:

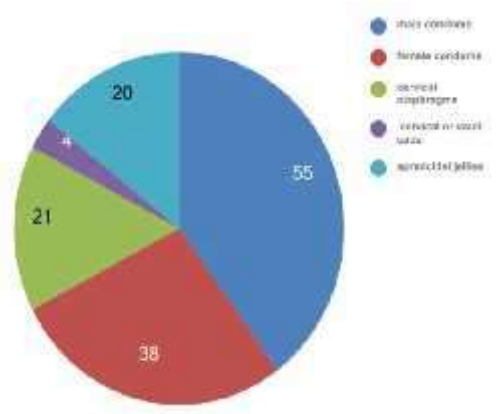
1. Type of contraception (hormonal) 2. Not a commonsideeffect- cancer 3. Necessity of contraceptives during lactation 4.Does Use of OCPs for a long time causesinfertility.

C. Barrier Contraception.

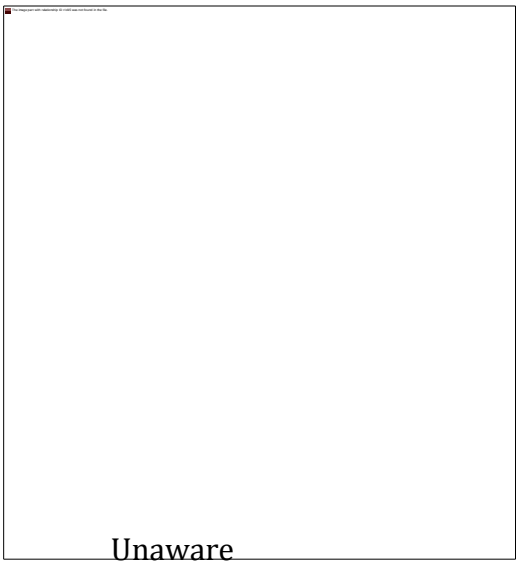
The average awareness percentage for this method was found to be 51 % (Refer Fig. 3).41% of the samples were aware of the fact that the problems associated with failed condoms are pregnancy and STDs due to breakage of condom or leakage through condom which may result from its poor quality. Refer to Fig. 4 for levels of awareness about types of barrier contraception.



Aware Unaware



Aware



Unaware

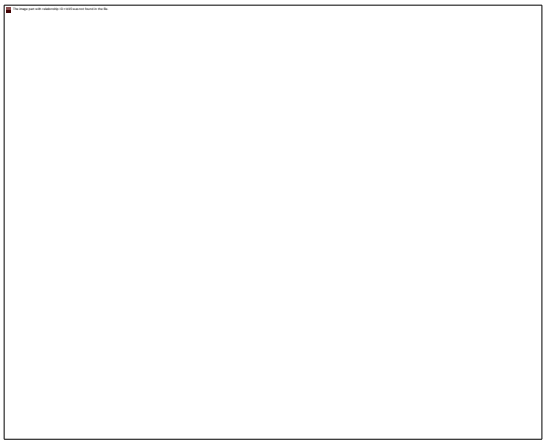
Figure 4:Awareness on types of Barrier contraception:

1. Male condoms 2.female condoms 3.cervical diaphragms 4. Cervical or vault caps, spermicidal jellies

D. Sexually Transmitted Diseases (STDs):

85% of the sample was aware of the full form of STDs, 82% were aware that condoms are the method of contraception that helps in prevention of STDs. Six sexually transmitted diseases were enlisted and the people were asked to tick the diseases they were aware about. (Ref Fig 5)



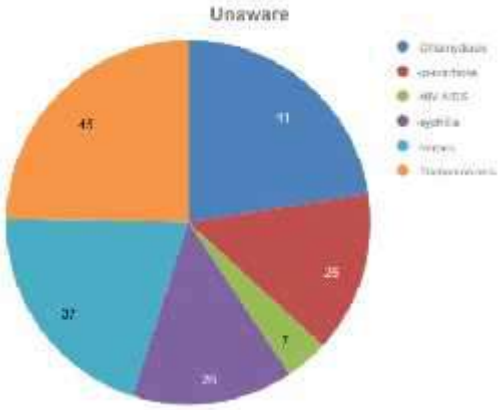


Figure 5: Awareness on STDs:

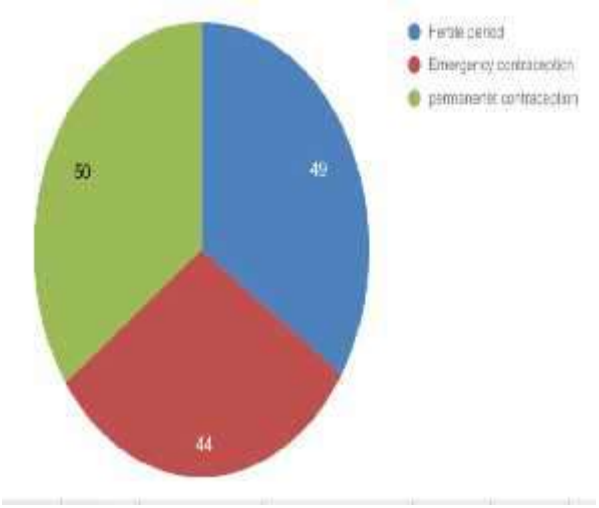
1. Chlamydiasis 2.gonorrhea, 3.HIV AIDS, 4.Syphillis, 5.Herpes,6. Trichomoniasis

E. Other Miscellaneous Questions (Refer Fig. 6 and 7)

Regarding the methods of emergency contraception, 73% were aware about the progestin only pill, whereas only 13% were aware about the Copper IUDs.

Aware Unaware



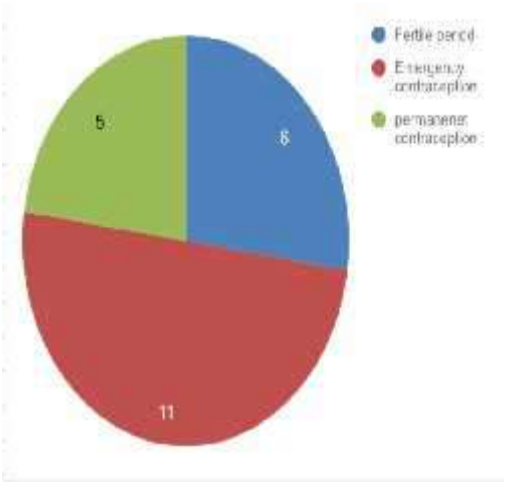


Figure 6: Miscellaneous questions 1.Is it necessary to be aware offertile period

2. Awareness of emergency contraception 3. Awareness of permanent contraception

Aware Unaware

Figure 7: Awareness on permanent contraception:

1. Is it for males/females/both? 2. It is also called – sterilisation 3.For males: Vasectomy 4. For females: Tubectomy.

Based on the overall sample size it was found that the awareness on contraception and STDs was 57%.

The awareness of females on Contraception STDs was 58% and males were 57%.

The questionnaires were sent online to 101 people, but the response was given only by 55 people. 45.5% of the recipients of the questionnaire did not respond, even after continuous follow up.

Discussion

Considering the difficulty of questions put forth to the sample population, the awareness levels were quite good in regard to contraceptives and their use, and sexually transmitted diseases (57%).

Most people did not identify the fact that a failed IUD could potentially cause an ectopic pregnancy. One surprising trend observed among the sample population in oral contraceptives was many people marking it as barrier contraception instead of hormonal contraception. A majority of the study subjects believe that using contraception to alter the menstrual cycle is unhealthy in the long run. (87%)

People (56%) also believe that being on the pills for a long time can cause trouble by completely nullifying the chances at becoming pregnant later.
Male condoms was the method of barrier contraception that everyone was unanimously aware about (100%) and cervical/ vault caps were the least known method of contraception among the study population. (7%)

The spread of sexually transmitted diseases is also a major concern owing to the modern life styles of people. 85% of the population is aware about sexually transmitted diseases, of which a majority (87%) were aware of AIDS followed by syphilis and gonorrhea (53% each).
Only 13% of the entire sample size was aware that copper IUDs are also a type of emergency contraception. People displayed a generally good awareness to emergency (80%) and permanent contraceptive methods (91%).

There is a lot of stigma associated with the discussion of contraceptives, thathave always been kept under wraps and have been a very sensitive topic. Multiple studies have been conducted to check the awareness amongst women alone [4-6]. A lot of difficulty was observed even during the collection of samples. Though particular care had been taken to avoid personal questions, many did not respond. Overall, 45.5% of the people haven't responded to the questionnaires sent across despite frequent follow up.

As mentioned above, a lot of questions were based on popular myths, and it was hardly surprising to see that most people still believe in those myths without even knowing why.
For example, some people even gave some very strange answers for the methods of contraception they were aware of, like pushing a stone into the vagina. Though most of the people believe that permanent contraception is for both males and females, some people still think that it's only for females. Contraception awareness studies must also be conducted amongst males, as there are fewer studies cornering this spectrum. [7-9]

The present study was conducted to assess the awareness and knowledge about various methods of contraception, which would ultimately reduce the rates of abortion. But many prospective trials have to be conducted in order to obtain more extensive data. [10-12].

Hormonal contraception which is highly common among women and not men. Many researches and studies are being carried out to develop allopathic anti-fertility drugs for men.[13,14] It would be valuable if studies were also conducted amongst teenagers , who usually present late for abortion as the awareness levels may be low. [15-17]. Counseling about contraception awareness would also help to a great extent as it will reduce the stigma around the topic and create more aware individuals.[18-20]

This study may not be very accurate because of the limited sample size, and as all the people in the sample were educated.

Conclusion

The overall awareness level, according to the study conducted was 57% with regard to use of contraception and sexually transmitted diseases in general Indian population which was from an urban population, with almost no difference in the levels of awareness of males and females. Though the awareness on contraceptives has definitely increased over the ages, the fact that the people may still not be implementing the various methods effectively remains. Awareness on contraception and about sexually transmitted diseases is of paramount importance for the development of our society and stabilization of the population here in India, more so because of the uncontrolled population inflation and the gross imbalance and discrepancy between the present population levels and the availability of resources, employment opportunities which will ultimately lead to a poor standard of living. These are the factors that will hinder or act as potential roadblocks in the progression of India from a developing to a developed country. Contraception, when viewed from this juncture, is not only a scientific method, but also a moral responsibility of the citizens, for a balance in the population and for better access of the limited resources available in our country.

Awareness on the Correlation between Periodontal Diseases and Cardiovascular Diseases – A Questionnaire Based Study among Cardiologists in Chennai

Maria Kurian[1], Radhika ArjunKumar[2], SreeDevi Dharman[3]

Graduate student[1] ,Reader[2], Department of Periodontics,

Senior Lecturer[3], Department of Oral medicine and Radiology

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction: Periodontal disease is common among adults and is a potential source of chronic inflammation. Although a direct causal link between periodontal diseases and vascular diseases has not been shown to date, there are numerous mechanisms through which periodontal infection may affect the onset or progression of atherosclerosis and Coronary heart disease (CHD). For those at risk of developing or those with preexisting cardiovascular disease, critical factors to consider include the presence of other medical conditions, such as diabetes, that may affect the cardiac disease; and also the presence of risk factors that may lead to periodontal diseases. The aim of this study is to assess the awareness among cardiologists on the correlation between periodontal diseases and cardiovascular diseases.

Materials and Method: An online questionnaire based study was conducted to assess the awareness on the correlation between periodontal disease and cardiovascular diseases among cardiologists in Chennai. Data was collected using a structured, self-administered questionnaire which was designed after reviewing recent articles, developments and also similar questionnaires that are based on the objectives of the study.The questionnaire was distributed online to cardiologists in and around Chennai of which 33 had responded. All questionnaires were anonymously collected and the data was kept confidential and not used for anything apart from the study purpose.

Result: The study results reveal that the knowledge and the awareness on the correlation between periodontal disease and cardiovascular diseases among cardiologists in Chennai is good.97% of the doctors were able to state that there is a proven correlation between periodontal

disease and cardiovascular diseases. 94% of them stated correctly that the etiology of periodontal disease is bacterial plaque.

Conclusion: Further seminars and workshops can be conducted in hospitals in order to educate the doctors on the advances on this correlation.Cardiologists may be able to detect pre-cardiac conditions by taking into account the periodontal health as well as prevent the progression from pre-cardiac to cardiac disease.

Keywords: *Atherosclerosis, Cardiologists, Periodontal disease, Conditions*

Introduction

Periodontitis is an inflammatory disease which is of microbial etiology. It causes destruction of the periodontium which consists of the gingival tissues, periodontal ligament fibers and also the surrounding alveolar bone. Due to this destruction, teeth become mobile and fall off. [1] National Health and Nutrition Examination Survey (NHANES III) carried out between 1988 and 1994 stated that 34.5% of dentate U.S. citizens 30 years and above had periodontitis with a relationship seen between the increasing age and periodontal disease [2]. And in developed countries, cardiovascular disease accounts for 50% of deaths [3]. Cardiovascular disease (CVD) is the leading cause of mortality in the United States[4-6].Several diseases such as atherosclerotic CVD,hemorrhagic stroke, congestive heartfailure, hypertension, Rheumatic Heart disease (RHD), and congenital heart defects comes under the wide list of Cardiovascular diseases.[7]Accumulating evidence shows that inflammation played a central role in the pathogenesis of CVD [8,9].Several infectious diseases have been implicated as possibly causing myocardial infarction (MI). A link between oral health and cardiovascular disease has been proposed for more than a century. There is concern about the possible links between periodontal disease (PD) and atherosclerotic vascular disease (ASVD). The 2 disorders share several common risk factors, including cigarette smoking, age, and diabetes mellitus. Patientsareoften presented with claims that Periodontal disease treatment strategies offer ASVD protection.In related research, periodontal disease has also been related to coronary heart disease (CHD). Several observational studies have indicated that periodontitis, a chronic inflammatory periodontal disease that results in the breakdown of bone that surrounds teeth, may be associated with an increased risk for MI.A periodontal disease causes a sort of chronic inflammation [10] which allows the bacteria to enter the bloodstreamby the micro ulceration of the epithelium of the periodontal pocket [11-13]. The contact between germs and macrophages causes a direct release of pro-inflammatorymediators (Interleukin IL-8, Tumor necrotizing factor – alpha TNFα), that facilitates the attraction of neutrophils from vessels (innate immunity). Increased hepatic synthesis of LDL cholesterol is favored by TNFα.It is seen that IL-6 released later helps in the productionof C-reactive protein (CRP) in the liver. This fact accelerates the atherosclerosis plaque progression.[14]C-reactive protein (CRP) is a classic marker for inflammation.[15] Periodontitis isshown to raise inflammatory markers such as CRP in the blood [16-18] which is an acute phase reactant protein considered to be a riskindicator for both periodontitis as well as

cardiovascular disease.[19-22] Hence, if cardiologists are aware of the correlation between the two diseases, early detection and treatment of the periodontal disease can be done thereby, reducing the risk for cardiovascular diseases. This study was conducted to find out the awareness already possessed by the cardiologists and to determine how the awareness could be improved if necessary.

Materials and Methods

An online questionnaire based study was conducted to assess the awareness on the correlation between periodontal disease and cardiovascular diseases among cardiologists in Chennai. Data was collected using a structured, self-administered questionnaire which was designed after reviewing recent articles, developmentsand also similar questionnaires that are based on the objectives of the study. The questionnaire was divided into three parts. The first part included questions based on demographic data, the second part consisted of questions related to their knowledge on the correlation between periodontal disease and cardiovascular diseases and the final part consisted on ways a cardiologist may help to prevent periodontal disease. The questionnaire was distributed online to cardiologists in and around Chennai of which 33 had responded. All questionnaires were anonymously collected and the data was kept confidential and not used for anything apart from the study purpose.

Result

The 33 cardiologists who participated in this survey were between the ages of 31 to 60 years. They had varied years of experience such as between 1 to 30 years of experience in their field. Of the 33 cardiologists, 28 were males and 5 were females. 97% of the doctors were able to state that periodontal disease is a type of bacterial disease and that there is a proven correlation between periodontal disease and cardiovascular diseases. 94% of them stated correctly that the etiology of periodontal disease is bacterial plaque whereas the remaining 6% believed dental caries as the etiology (Fig.1). 79% of the cardiologists believed the inflammation of the gingiva as the initial sign of periodontal disease and 21% suggested it to begingival bleeding (Fig.2). When asked on the management of the periodontal disease, 88% suggested cleaning the teeth,

9% suggested mouthwash and 3% suggested antibiotics (Fig.3). They all agreed that complete management of the disease is required to reduce the risk of cardiovascular diseases. 97% of the cardiologists had received some information on the correlation between periodontal disease and cardiovascular disease from medical college. All of them enquire their patients for a history of periodontal disease (Fig.4). All of them agree that all doctors must educate their patients on the importance of oral health. 91% of them examine their patients for periodontal disease (Fig.5) and all of them refer their patients to a dentist for an oral examination. 88% are able to identify a case of periodontal disease on their own (Fig.6). All of them agree that there is an increase in CRP levels during inflammation and can be used to assess the functioning of the cardiovascular system. 79% of the cardiologists state that during periodontal disease, monocyte infiltration, endothelial damage and gram negative bacteraemiaoccur(Fig.7). All the doctors agree that dental checkups must be conducted for all patients (Fig.8).

Discussion

Periodontitis is a major public health concern because of its high prevalence in the population and its negative impact on oral health. In addition, as a progressive, chronic inflammatory disease, untreated periodontitis has the potential to lead to CHD [23]. Periodontal disease is a risk factor for the development of various systemic conditions like diabetes, cardiovascular disease, osteoporosis and adverse pregnancy outcome. [24] Risk factors associated with the development of PD include local, systemic, and genetic factors. Although several bacterial species are currently recognized as causally associated with periodontitis, merecolonization of the subgingival niche by these species is not sufficient for disease to occur. Instead, PD is thought to evolve from the stage of gingivitis, that is, a local inflammatory process without concomitant loss of periodontal tissue support that likely represents a stable, largely protective host response to periodontitis, an environment characterized by loss of connective tissue

attachment and alveolar bone, influenced by detrimental environmental exposures and specific genetic predispositions that are likely important determinants of susceptibility.Risk factors of periodontal disease include poor oral hygiene; cigarette smoking and also systemic conditions such as diabetes mellitus, rheumatoid arthritis etc. In addition, a number of genetic polymorphisms have been variably associated with propensity for periodontitis and ASVD.Risk factors of ASVD are multifactorial and involving genetic, environmental, and lifestyle factors. The associated risk factors include ethnicity, age, and family history of ASVD, which cannot be changed and those factorsthat can be modified or even controlled, includinghypertension, smoking, obesity, physical inactivity and diabetes mellitus. There is a clear role of the interactions between risk factors with cellular and non-cellular mechanisms in the slow process of atheromatous plaque, with unreliable evidence that by eliminating the risk factors, it is possible to prevent the atherosclerotic process and its clinical manifestations. In addition factors such as chronic inflammation which is associated with long-term progression of atherosclerosis, there are also “triggering factors” which are acute and include increased inflammation and also a cascade of hemostasis and thrombosis. Atherosclerotic plaqueruptures with thrombosis, leading to occlusion of the vessel progressing to clinical conditions such as MI or stroke.Many risk factors are shared between ASVD and PD and which could form the relationship between them. Various factors such as old age, smoking, alcohol, race, socioeconomic status, male gender, diabetes mellitus, and obesity are associated with both ASVD and periodontal disease.There is proof that periodontal bacteria and its byproducts of the bacteria have an effect on different systems in the body[25]. Most of the cardiologists had some knowledge on the etiology of periodontal disease of the bacteria and its effect on the body. For instance, a recent study of physicians knew that bacteria was the etiology of periodontal disease (86%)[26]. The current study had shown similar results, with 94% of the cardiologists reporting bacteria as the etiology of periodontal disease. Periodontal microorganisms which are found in dental plaque appears in the bloodstream and is directly proportional to the severity of the periodontal infection and canaffect distant sites. They have been thought to lead to systemic inflammation,impairment of insulin action, vast increase in glycogenesis in the liver, and can also alter the gut microflora which leads to systemic inflammation and metabolic changes. Porphyromonasgingivalis counts is found to be higher in sub-gingival dental plaque found in periodontal disease, where it leads to

inflammation and periodontal destruction.The organisms enter the bloodstream following tooth brushing,and has been found in the intima of distant blood vessels including in coronary arteries, where it proliferates, initiating an inflammatory cascade leading to apoptosis and consequent endothelial dysfunction, which is associated with hypertension. It also stimulates foam cell production in the intima leading to atherosclerosis. P. gingivalis has been shown to increase low-density lipoprotein (LDL) and total cholesterol levels by up-regulation of a protein which impacts circulating levels of LDL cholesterol in mice.There are two plausible underlying causal structures that can explain these findings: first, that periodontal disease (PD) causes CVD, and second, that PD and CVD have somecommon cause such as smoking or genetic polymorphisms that can lead individuals to develop both PD and CVD.From a study conducted in Iran, it was seen that 82% of the cardiologists agreed that inflammation is the key link between cardiovascular disease and periodontal disease [27] which is almost similar (79%) to the results from this current study. There is said to be an unknown genetic factors that may influence both the inflammatory diseases which is periodontal disease and cardiovascular disease and may therefore explain the association found in clinical studies [28].Apre-determined genetic phenotype is used to determine the risk of developing both atherosclerosis and infection. This is a hypothesis in which the presence of periodontal pathogens causes a susceptible person to developperiodontal disease. In the same person, atherosclerosis may develop, but, in this model the periodontal disease does not lead to the atherosclerosis.Only 54% of the cardiologists at the Iran study had some sort of knowledge on the correlation between the two diseases, whereas in this study, 97% of the cardiologists were said to have been oriented about the correlation. Only 80% of the doctors from the Iran study believed that doctors should educate the patient on the importance of oral health. But from this study it is seen that all the doctors agreed that educating their patients on oral health is very important. Physicians were asked if they perform oral examinations on their patients, 21% responded that they never perform oral examinations on their patients because they were not sure on how to diagnose it [29]. The most possible explanation of how periodontitis can lead to the development of CHD is that periodontal microorganisms and their products located in the periodontal pockets may enter into the circulation and lead to an inflammatory reaction. Mediators produced as part of this host response leads to the development, maturation and instability of fatty lesions (atheroma) in the

arteries, thereby increasing the risk of a CHD adverse event. Research shows that the microorganisms which enter the bloodstream during chewing, brushing, flossing or scaling depends upon the patient's dental flora which gives a picture of the periodontal status [30,31]. Bacteraemia is common, and is caused by a wider range of microorganisms in patients with periodontitis than those who are in an healthy state. Another possible mechanism by which periodontitis might contribute to CHD risk is that the antibodies which are produced as an inflammatory response to bacterial plaque may promote the development of atheroma by reacting with the endothelial cells and with blood lipids [30, 31]. Studies have proved that treating the periodontal disease reduces the inflammation within the circulation. Periodontal therapy is seen to have positive effects on two risk factors which are important markersof CHD: levels of C-reactive protein (CRP); and measures ofthe functioning of endothelial cell [30-33]. C - reactive protein (CRP) is a liver-produced, acute-phase reactant that serves as a systemic marker of inflammation. Levels of CRP can be used to monitor patients with overwhelming infections, and elevated CRP levels have been demonstrated in persons with ischemia and myocardial infarction.When monitoring a patient's acute-phase response, a serum CRP concentration exceeding 10 mg/L is generally regarded as the threshold indicative of significant inflammatory disease.Thus adequate awareness on the correlation between periodontal disease and cardiovascular disease is necessary among cardiologists to help promote better health and treatment to their patients.Studies have suggested that periodontitis is associated with coronary heart disease and cerebrovascular disease.Periodontitis is a chronic infection by Gram-negative bacteria that affects the supporting structures of the teeth.A mechanism proposed that periodontitis creates bacterial pathogens, antigens, endotoxins, and inflammatory cytokines that lead to athero-genesis and also thromboembolic events. In response to infection and inflammation, certain persons may exhibit greater expression of local and systemic mediators and may thereby be at increased risk for atherosclerosis. The atherosclerosis process may result in decreased arterial patency and/or decreased compliance of the vessel. Ultimately, atherosclerotic lesions may fissure and/or rupture, resulting in occlusion of the vessel lumen, precipitating a myocardial infarction or stroke.

Conclusion

ItwasseenthattheoverallawarenessamongCardiologistsinandaroundMogappaironthecorrelationbetweenperiodontaldiseaseandcardiovasculardiseaseswasgood.Allofthem agreedthatduringperiodontaldisease, thereisinflammationofthegingivaandthatcompletemanagementofperiodontaldiseaseisrequired in order to facilitate better cardiac health. All the doctors inquire the patients on their oral health and also send their patients for a dental check up. They agreed that there is a rise in the CRP levels during periodontal disease which is a marker to assess the cardiac health. Finally, all of them agreed that Cardiologists should advice their patients on the importance of oral health. Various programs like seminars, symposiums or any other awareness programs on the correlation of periodontal disease and cardiovascular disease can be arranged for doctors at hospitals so that it can benefit their patients in the long run.

Abstract

Introduction: A rotary instrument is used to remove or reduce tooth matter and to shape teeth during endodontic procedure. Rotary instrument includes burs and endodontic files. Various brands of rotary instruments are currently available in the market which includes dentsplyprotaper, Mtwo, endostar, k3 XF files, Heroshaperetc. The choice of rotary instrument by a dentist is governed by various factors like their efficiency, ductility, sharpness, cross section and flexibility.The aim of the study is to find the rotary instrument usage and preferred brand of rotary instrument among endodontists working in dental colleges, Chennai.

Materials and Methods: An online questionnaire based study was conducted among 97 endodontistsworking in dental colleges in Chennai.A total of 10 questions consisting of both open ended and close ended questions related to usage, preferred brand and properties were included in the questionnaire. Data werecollected from the filled questionnaire and analysed. Descriptive statistics was used.

Results: From the study it was reported that 88% of endodontists use rotary instruments for endodontic procedures in their clinical practice.The most preferred brand of rotary instrument used by endodontists is Mtwo(40%) because of its good cutting ability and shaping followed by 20% k3, 18% protaper, 6% heroshaper and 36% combination of different rotary instruments.

Conclusion: Majority of the endodontists preferred using rotary instruments and nearly half of them opt to use mtwo file in their clinical practice.

Key Words:*rotary instruments, endodontists,NiTi, flexible.*

Introduction

The root canal treatment consists of removal of bacterial debris from the canal by biomechanical means like cleaning and shaping to prevent reinfection (1).Root canal anatomy is quite complex and to clean and shape these canals successfully requires appropriately designed instruments (2). The cleaning and shaping of root canal systems by various techniques includes usage of hand instruments and rotary instruments.The aim of root canal treatment is to prepare tapered funnel shape with the smallest diameter at the apex and the widest diameter at the canal orifice.

Stainless steel instruments have been used for a long time in endodontics; these instruments are ineffectivein the maintenance of the original canal shape because of their low flexibility and its time consuming (3). Lack of flexible nature of stainless steel instruments has led to procedural errors and decreased success rate (4,5). Hand instruments have the tendency to straighten themselves after using in a curved canal and, if used improperly, they could straighten curved canals (6).

The engine driven Nickel-Titanium (NiTi) rotary instrumentshave been engaged in faster and easier root canal system (7).Rotary instruments are preferred by practitioners for their super-elasticity, excellent flexibility, improved cutting efficiencyand better centering ability(8).Rotary instruments have been found to removefilled restorative material efficiently and safely (9,10) . Rotary instruments has shown increased fatigue resistance to sterilisation preventing torsional stress (11).However there are certain disadvantages concerned with rotary instruments such as cost and instrument fracture (12).

Various brands of rotary instruments are available in market and currently used by endodontists which includes k3,Mtwo ,heroshaper, protaper , endostar, HyFlex, etc.The aim of this study isto find the rotary instrument usage and the most preferred brand of rotary instrument used among endodontistsworking in private dental colleges in Chennai.

Materials and Methods

An online questionnaire based study was conducted among endodontists working in dental colleges.The Questionnaire was circulated among120 endodontists working in private dental colleges in Chennai, India through mail. This study was conducted from 15thDecember - 31stDecember 2016.Ethical clearance was obtained from the Institution Review Board for conducting the survey.A sample size of 94 was calculatedbased on the prevalence of rotary instrumentsusage in the previous study (17). Convenient sampling methodology was followed to select the study samples. Mail was sent to the endodontists explaining about the purpose of the study. Out of 120 endodontists,97accepted to participatein the study.A pretested questionnaire was used and the questionnaire consists of 10 questions which were both open ended and close ended questions. There was neither time limitation nor true/false based questions. The questions were related to the usage, brand, frequency, advantages and limitations of the rotary instrument used. Questions in the questionnaire used were selected from national and international surveys. Participation was voluntary and anonymous and no personal data were collected.

Questionnaire was mailed to them and completely filled questionnaire was considered for analysis. The returned questionnaire containing unanswered questions were excluded. Data was entered in the excel sheet and descriptive statistics were obtained from the data collected.

Results

A cross sectional study was conducted among 97 endodontists working in dental colleges in Chennai and it presented an overall view about the choice of rotary instrument used and preferred among endodontists.

The results of the study showed that 31% of endodontists have used rotary instruments in endodontic practice and 13 % used only hand instruments for cleaning and shaping , while 56 % used combination of both rotary and hand instruments,asthey claimed rotary instruments are not used in the anterior tooth region due to lack of cuspal and dentinal walls (figure 1).It was found from the study that around 90 endodontists ie.88% preferred to use rotary instruments for cleaning and shaping of the root canal and about 12 % endodontists preferred to use hand instruments (fig 2).

. Based on the physical properties of rotary instruments about 47 % of endodontists has chosenitflexible which is an important property for working in straight and curved root canals. About 32% of endodontists has reported corrosion resistance as an ideal property and 21% has claimed rotary instruments to be fatigue resistant (figure 3).

Depending upon the frequency of rotary instruments usage in a week for endodontic procedure, 31 (32%) endodontists has used it only once in a week.The highest frequency of rotary instruments usage was found to be three times in a week by 53 endodontists (54.7%) . while about11 (11.3%) endodontists use rotary instruments five times in a week; rotary usage formore than 5 times in a week was the least reported 2 %. This frequency is based on experience with rotary instruments(table 1). The most preferred brand of rotary instrumentisMtwoby40% ofendodontists, followed by 20%k3, 18 %protaper,6% heroshaper and6%ofendodontists use other different brands of rotary instruments(fig 4).About36% of endodontists use combination of one or more brands of rotary instruments for effective cleaning and shaping.Most commonly used combination of rotary instruments among endodontists in the study were heroshaper and protaper for effective cleaning and shaping (fig 5). Question about advantages of rotary instruments revealed the following response,35% of endodontists preferred rotary instruments for its good cutting ability while22%preferred rotary for its perfect shaping of canals.18 % of endodontists preferred rotary instruments for its time saving property and 14% for efficiency of the rotary instrument. Very few endodontistschoose rotary instruments to be economical 6% and for its long term usage 5% (figure 6). The most commonly associated limitation of rotary instrument was file fracture by 39(40%) of endodontists . Theleastcommonly reported limitation of rotary instrument is ledge formation12 (13%).Other common disadvantages reported by endodontists are canal perforation 20 (21%) and excess dentin removal 26 (26%)during Canal preparation by rotary instrument (table 2).

Discussion

The cleaning and shaping of root canal is one of the important step in endodontic therapy. Cleaning and shaping remove all the tissue debris and inner layers of root canal dentin regardless of the instrumentation technique **(**3**) .**Rotary instruments has a greater ability to negotiate curved canals and reduce iatrogenic errors by maintaining the original path and allows larger apical preparation of canals (13).Hence a study was done to find the rotary instrument usage among endodontists working in dental colleges in Chennai. The investigations from our study show that most of the endodontists about 88% prefer using rotary instruments for their endodontic practice. In a study conducted by Jyothi.Set al among practitioners in chennai, 2016it was found that non- rotary manual endodontic files were commonly used by the practitioners (14)

There are various advantages of rotary instruments which include flexibility ,good cutting ability ,time saving and perfect shaping of the canals. The super-elastic property of NiTi, allows safe and effective instrumentation of curved and narrow root canals using hand piece driven instruments operated at low speed (15).It has been reported in our study that flexibility (40%) is an ideal property for usage of rotary instruments.In an invitro study by Peter et al, 2012 it was reported that high fatigue resistance and flexibility was enhanced by HyFlex rotary instruments (16) . Machado et al,2010compared the disinfectant property of two rotary instruments, ProTaper and Mtwo reduced the amount of bacteria in the mechanical disinfection of the root canal system (17).Few disadvantages are also concerned with the use of rotary instruments which include cost, instrument fracture, difficulty to use and lack of knowledge (4). The major limitation reported was file fracture by 40% of endodontists . Flexural fatigue of rotary instruments is the main reason for file fracture (18).Schirrmeister, J. F. et al 2006, compared hand file and rotary instruments in removing the guttapercha from curved root canals and reported thatRaCe system is an efficient and safe device for gutta-percha removal in curved root canal compared to flex master, protaper and hand instruments (19).

Recently introduced rotary NiTi files are able to produce a uniformly tapered canal configuration without canal transportation. Electropolishing may have beneficial effects in prolonging the fatigue life of rotary NiTi instrumentsbyreducing themsurface irregularities that serve as points for stress concentration and crack initiation(20).However, unpredictable

instrument separation remains a deterrent to their popularity. Moreover, cost of rotary files also restrained their use. Majority of practitioners only replaced their instruments when signs of distortion and bluntness were obvious, which is likely to result in a higher risk of instrument separation in the canal (4)

Mohammad Ali et al ,2009study on the usage of rotary instruments among general dentists and endodontist, general dentists and dental students require more training and more comprehensive education regarding rotary instruments and techniques (21).It was reported by 17% of endodontists that rotary instruments helps in faster canal preparation and is time saving. Abu-Tahun et al,2015 investigated among fifth year undergraduate dental students in Australia thatrotaryfiles were able to prepare root canals faster with more preparation accuracy compared to hand instruments for same tooth(22).Endodontists were significantly more satisfied than those treated by general dentists mainly because of the shorter treatment time by using rotary instruments (23).

The most preferred brand of rotary instrument reported was Mtwo (40%) followed by combination of different rotary instruments like Heroshaper ,protaper.Ina study done by AlaviehVahidEt al,2009 in Australia four rotary instruments were compared and assessed for preserving canal curvature, preparation time and change of working length it was reported that Mtwo rotary instruments required significantly less instrumentation time, and the ProTaper significantly changed the canal curvature(5). In our present study, Canalperforationwas reported by 26% of the endodontists . Bier et al , 2009 estimated the ability to induce dentinal damage during canal preparation using NiTiandfoundthatProTaper, ProFile, and GT preparations resulted in dentinal defects in 16%, 8%, and 4% of teeth, respectively during canal preparation (24).In the present study it was reported that excess dentin removal 26% is one of the limitation of rotary instruments.Ramanathan et al 2017, in an invitro study concluded that ProTaper Universal and ProTaper Next should be used judiciously, as it causes higher thinning of root dentin of the root when compared with Mtwo (25).In the present study, the assessed frequency of rotary instrument used by endodontist was three times (54%) in a week.Parashos et al, 2014 conducted a survey among Australian dentist and reported about 70% of dentists used the instruments two to five times,19% used six to ten times and 12% used instrument only once this usage paws basedonfile size and

canal shape(4) .Rotary instrument usage increased with increasing work experience suggesting that dentist with less experience are less likely to use (21).

Therefore it is acknowledged that interpretation of any survey data must consider the possibility of incorrect answers because of factors related to questionnaire design, question wording and respondent factors.Generalisability of this study may be limited, as it represents only views of practitioners working in dental colleges in Chennai.

Conclusion

It can be concluded from the study thatmajorityof endodontists use rotary instruments for endodontic procedures in their clinical practice. Nearly half of the study participants reported that the most preferred brand of rotary instrument wasMtwo because of its good cutting ability and shaping.

Annexure 1: Questionnaire

1. what type of instruments do you use for endodontic procedure?

a. Rotary instruments

b.hand instruments

c.Combination of a and b.why?

2. Which type of instrument do you think is more convinient ?

a.rotary instruments

b.hand instrument

3.Which brand rotary instruments do you prefer?

a. K3

b. Mtwo

c. Heroshaper

d. Protaper

e. Others

4.Do you use combination of rotary instruments?

a.yes

b.no

5.If yes , mention the combination of rotary used

6.How frequently(in a week) do you use rotary instruments?

a.once

b.three times

c. Five times

D. More than 5 times

7.Why do you prefer using rotary instruments?

a.Time saving

b. Efficiency

c.perfect shaping

8.what are the advantages of the rotary instrument you use?

a.long term usage

b.cutting ability

c.Cross section

d. Economical

9.What property do you think is important for rotary instruments?

a.flexibility

b.corrosion resistant

c.fatigue resistant

10.what do you think is the limitation of endodontic instrument

a.file fracture

b. Excessive dentin removal

c.canal perforation

d.ledge formation

Cognisance of Endodontic Mishaps Among UndergraduateStudents

M.Indhumathi[1], Nivethithan.T[2], Hemavathy.O.R[3],

Abstract

Introduction: The main aim of Root canal treatment is to restore the diseased pulp. Endodontic mishaps are some accidental happenings that occurs during the procedure it may be seen during access opening, instrumentation, obturation and post space preparation. So it is important to know about the errors occurring during the root canal treatment. The aim of the study is to evaluate the awareness of endodontic mishaps among undergraduate students.

Materials and Methods:A cross-sectional questionnaire based study on awareness of endodontic mishaps among undergraduate students. Data were collected from 200 undergraduate students of Saveetha dental college, Chennai. Correct responses to the questions were allocated 1 mark while wrong response received no mark. Statistical analysis was performed to analyse the study.

Conclusion: This study is useful to gain knowledge about the procedural errors during root canal treatment.

Key Words: *cognisance, knowledge, mishaps*

Introduction

Endodontics generally denotes to the procedures relating to the treatment of diseased dental pulp occurring due to effects of long standing dental caries.[1]The mainpurpose of the endodontic treatment is to relieve pain and maintain the structure and integrity of the tooth in the oral cavity.[2,3]Root canal treatment forms the core of endodontic procedures and its primary goal is to debride and sterilize the necrosed pulp tissue and to obturateall root canals to form a fluid-tight seal on the apical foramen of the tooth, so that any possibility of a secondary infection occurrence due to the mouth cavity or periradicular tissue leakage into the root canal system can be avoided.[4]Endodontic mishaps or procedural accidents are those unfortunate accidents that happen during treatment, some owing to inattention to detail, others being totally unpredictable.[5,6,7]. These endodontic mishaps play a vital role in determining the prognosis of the treatment done to the diseased teeth.[14,15]

Materials and Methods

A cross sectional questionnairetodetermine the cognisance of endodontic mishaps among undergraduate students was designed .Data were collected from 200 undergraduate dental students of Saveetha dental college, Chennai.The undergraduate dental training in Saveetha dental college is divided into the pre-clinical levels first and second year of study and the clinical levels [3rd and 4th] of study. This study was conducted for third year, fourth year and internship students. There are twenty directquestions regarding the endodontic mishaps, their identification and its prevention.[12,13] Each question had four options and each correct responses to the questions were allocated 1 mark and the wrong responses revealed no marks. The questions are given below.In this study the percentage of awareness has to be noted based on their knowledge and the statistical analysis was performed to analyse the study.

Results

Endodontic treatment can be considered a stressful procedure for undergraduate students. It usually requires competent technical skills and experience, as well as an understanding of pulp anatomy and its variations.[15] Knowledge of root canal morphology and tooth pulp chamber will allow the student to avoid any mishaps. In many cases, insufficient knowledge makes endodontics more difficult than necessary by not creating a proper access that allows

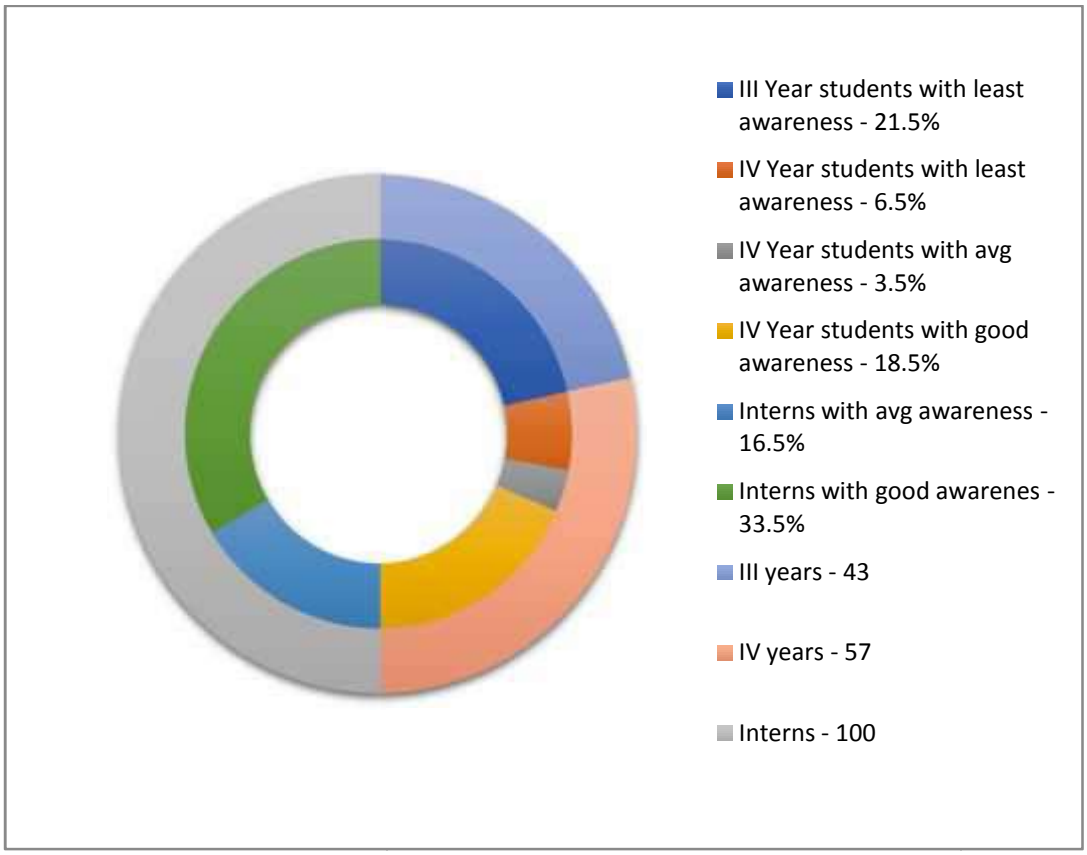
straight line approach to the canals. This is especially true for mesiobuccal canals in both molar teeth. Perforation of pulp chamber can occur during a fruitless search for the canal orifices, drilling a tooth with a completely calcified chamber, orienting the bur to the wrong direction, or looking in the wrong direction for the other canal. Students reported gouging and perforation during access cavity preparation. This is considered normal for undergraduate student.[16]

In order to reduce the incidence of iatrogenic defects, step-down technique is recommended for undergraduate students. This technique depends on the use of larger instruments at the canal orifice during preparation, then working down the root canal with progressively smaller files.[16,17] This offers several advantages, including straighter access to the apical region and enhanced tactile control, as well as improved irrigant penetration and suspension of debris. Using this approach, most of the problems that occur during root canal instrumentation can be avoided.[18,19]

The study records based on the questionnaire, table 3 showed that all 200 students contacted regarding the study responded positively agreed to participate. These 200 students included 72 males and 128 females; they all belonged to undergraduate clinical training in Saveetha Dental College which includes third year, fourth year and internship students. [8,9]Among the 200 students, third year students accounted to 43 [21.5%], final year students accounted to 57[28.5%] and interns accounted to 100[50%] of the total participants. The questionnaire circulated had 20 questions and the least number of correct responses to any of those 20 questions accounted to 110 [55%]. By analysing the data obtained from the questionnaires , showed that almost all third year students [21.5%] who participated had the least awareness, among 57[28.5%] final year students who participated; 37 students [18.5%] had good awareness, 7 students[3.5%] had average awareness and 13 students [6.5%] had least awareness; and among all interns who participated 100 students[50%], 67 students [33.5%] had good awareness and remaining 33 students [16.5%] had average awareness. So based on the data collected the table 4, shows the results indicate that; 44[77%]of 57final year students and all 100 interns who participatedhad above average awareness;37 [65%] of 57 total final year students and 67 [67%] of 100interns had good awareness among the total 200 participants. In total comparing all students, the interns had good awareness to endodontic mishaps, which can be clearly attributed to their clinical experiences and knowledge acquired during their undergraduate training.[10,11]

Table 1: Data obtained from questionnaire based on the criteria of cognisance of endodontic mishaps among undergraduate students.

Year of study	**Correct responses [Out of 20 questions]**	**No of students who answered correctly.**	**Awareness among the students.**
Third year	5-10	43 [21.5%]	Poor
Final year	15-20	37 [18.5%]	Good
	10-15	07 [3.5%]	Average
	5-10	13 [6.5%]	Poor
Internship	15-20	67 [33.5%]	Good
	10-15	33 [16.5%]	Average



Graph 1: Doughnut chart showing data obtained.

Table 2: Showing the aggregate data representing the above average and good awareness among undergraduate students.

Year of study	**Number and percentage Of students from each year among 200 UG students**	**Number and percentage Of students among their respective batches**	**Awareness among the students.**
Third year	43 [21.5%] of 200	43 [21.5%]	Least
Final year	53 [28.5%] of 200	37 [65%] of 57	Good
		44 [77%] of 57	Good + Average
Internship	100 [50%] of 200	67 [67%] of 100	Good
		100 %	Good + Average

Discussion

The study was conducted based on a self prepared questionnaire circulated among 200 undergraduate students of Saveetha dental college, Chennai. 72 males and 128 females answered the questionnaire based on this study.They belong to 18-24 yrs of age group.This survey was done among undergraduate students studying third year, fourth year and doing internship of Bachelor degree of dental surgery in Saveetha dental college.[20] The data obtained was categorised individually for all 20 questions and the resulting correct responses were considered to determine the awareness among students.

Table 3: Data of the questionnaire

Questions	**Option A**	**Option B**	**Option C**	**Option D**
1.Which age group do you belong to?	18-24	25-30	31-40	41-60
2.Mention your educational qualification	Secondary education[school]	Bachelor Degree	Master Degree	Diploma
3.Endodontic mishaps are most commonly associated with?	Access related	Instrument related	Obturation related	None of the above
4.Which is the least common access related error you will face during	Treating wrong tooth	Missed canals	Access cavity perforations	Crown fracture

RCT?				
5.Which is the most common Instrument related error you will face during RCT?	Ledge formation	Canal perforation	Instrument separation	None of the above
6.What are the errors which occurs during obturation in RCT?	Over or under extended root canal fillings	Nerve parasthesia	Vertical root fractures	All of the above
7.What are the other important errors that occurs after RCT?	Post space perforation	Tissue emphysema	Both a&b	None of the above
8.Under filling of root canal is most commonly seen in ?	Over instrumentation	While applying very less pressure on condensing the coronal portion	Both a&b	None of the above
9.What are the causes for Missed canals during RCT?	Grossly decayed tooth	Faulty access cavity design	Improper knowledge of canal morphology	All of the above
10.Furcation	Poor access	While doing	Working length	None of the

gets perforated while doing RCT is most commonly due to?	preparation	cleaning and shaping	determination	above
11.Broken instrument is due to?	Use of deformed files	Excessive pressure to the files	Reuse of files for more patients	All of the above
12.Over filling during obturation is most commonly due to?	May occur with soft materials or debris	Hard materials like gutta percha or silver cones	Both a&b	None of the above
13.Common errors that occur during post space preparation ?	Deviation from normal morphology	Removing excess Guttapercha	Both a&b	None of the above
14.How to prevent missing canals during access preparation?	Check for the canal anatomy	Good preoperative radiographs	Both a&b	None of the above
15.How to prevent instrument separation during RCT?	Avoid reusing the files	Use of NiTi files	Both a&b	None of the above

16.How to prevent perforation of crown or root	Use standard burs in optimal angulation	Proper access cavity design	Both a&b	None of the above
17.How to avoid ledge formation during bio mechanical preparation	Use files in sequence	Inaccurate working length	Both a&b	None of the above
18.How to prevent canal blockage	Use step back technique	Use adequate irrigation	Both a&b	None of the above
19.How to prevent instrument aspiration	Use rubber dam isolation	Use cotton roll isolation	Both a&b	None of the above
20.How to prevent nerve paresthesia	Avoid over instrumentation	Ensure confinement of filling material inside the canal	Both a&b	None of the above

Table 4: Data of correct and wrong responses by both males and females for each question.

No of questions	**Correct responses out of 200 students.**	**Wrong responses out of 200 students.**

	[Both males and females]	**[Both males and females]**
1.Which age group do you belong to?	200	0
2.Mention your educational qualification	200	0
3.Endodontic mishaps are most commonly associated with?	113	87
4.Which is the least common access related error you will face during RCT?	167	33
5.Which is the most common Instrument related error you will face during RCT?	178	22
6.What are the errors which occurs during obturation in RCT?	123	77
7.What are the other important errors that occurs after RCT?	165	35
8.Under filling of root canal is most commonly seen in ?	154	46
9.What are the causes for Missed canals during RCT?	134	66

10.Furcation gets perforated while doing RCT is most commonly due to?	123	77
11.Broken instrument is due to?	112	88
12.Over filling during obturation is most commonly due to?	110	90
13.Common errors that occur during post space preparation ? 14.How to prevent missing canals during access preparation?	125	75
15.How to prevent instrument separation during RCT?	156	44
16.How to prevent perforation of crown or root	178	22
17.How to avoid ledge formation during bio mechanical preparation	111	89
18.How to prevent canal blockage	104	96

19.How to prevent instrument aspiration	173	27
20.How to prevent nerve paresthesia	145	55

Table 5: Criteria for evaluating cognisance of endodontic mishaps among undergraduate students.

Correct responses [Out of 20 questions]	**Awareness level**
15-20	Good
10-15	Average
5-10	Poor

Conclusion

Based on this questionnaire, it can be concluded that students in their internship periodhad greater cognisance about mishaps occurring during endodontic procedures among all undergraduate students.

Dental Caries and its Relation to Diabetes among Out Patient Visiting Private Dental College and Hospitals in Chennai – A Cross Sectional Survey

Savitha P [1], Meignana Arumugham.I [2] , Pradeep.S [3]

Graduate Student [1],Professor [2],Department of Public Health Dentistry

Senior Lecturer [3],Department of Conservative Dentistry and Endodontics

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Dental caries are common chronic disease conditions that cause pain and disability across all age group. If left untreated, dental caries lead to pain, infection, abscess, tooth loss, and eventually eduntulism. Oral health habits are measures people learn and practice regularly in order to maintain good oral health or prevent oral disease.

Aim: The aim of the study was to assess the dental caries and its relation to diabetes.

Materials and Methods: The samples were composed of 120 subjects of diabetic patients. The data were gathered by pre – tested questionnaire, clinical examination for caries experience using DMFT index. The pre-tested questions were designed to determine the level of dental caries incidence being after diagnosed with diabetes and their frequent dental checkups.

Results: The mean DMFT value for male was 2.2 for age group 35 – 44 and 2.8 for 45 – 54 and 3.3 for 55 – 64 and 3.9 for 65 –74. The mean DMFT value for female was 2.7 for age group 35 – 44 and 3 for 45 – 54 and 3.2 for 55 – 64 and 3 for 65 – 74. The mean DMFT score for male and female increases according to their age group.

Conclusion: The present study confirmed that the presence of dental caries was not significantly elevated in diabetic patients, but it increased with age. And also found that female diabetic patients are more prone to dental caries with increase in age. Furthermore the diabetic patients reqires improvement in their general and oral health behaviour.

Key Words*: DMFT, Diabetic, Caries, Age, Incidence*

Introduction

Oral health conditions are known to affect various aspects of quality of life [1].Diabetes is a common chronic metabolic disorder which affects millions of people. Diabetes is characterised by sustained hyperglycaemia affects multiple organ system together with oral cavity [2]. There are two basic types of diabetes: types I diabetes caused by autoimmune damage to the pancreatic beta cells resulting in failure of insulin deficiency. While type II diabetes occurs as a result of insulin resistance with relative insulin deficiency [3]. The oral manifestations include xerostomia, gingivitis, periodontitis, dental caries and opportunistic infections of tongue and oral mucosa [4].Oral health habits are measures people learn and practice regularly in order to maintain good oral health or prevent oral disease. [5]

Dental caries are common chronic disease conditions that cause pain and disability across all age group. If left untreated, dental caries lead to pain, infection, abscess, tooth loss, and eventually eduntulism[6]. It is important to know that patients with DM are susceptible to other oral conditions, such as periodontal and salivary disorders (dry mouth), which could increase their risk of developing new dental caries.

Increased counts of *Mutans streptococci* and*lactobacilli* are some of the factors implicated to be responsible to predispose diabetics to higher incidence of dental caries [7].The increased risk of dental caries would be related to certain factors such as poor oral hygiene or a lack of blood glucose control [8]. The association between diabetes and dental caries, particularly among adults has gained less attention.

Some studies have demonstrated increased caries incidence in diabetes, while other have shown similar or decreased caries rate [9]. The present study examines whether there is greater incidence of dental caries among diabetic patients.

Materials and Method

The pre- tested interviewer administrated questionnaire based cross sectional survey was conducted among the diabetic patients who attended private dental hospitals. The sample of one hundred and twenty diabetic patients was recruited into study. The diabetic patients included were both type I and type II diabetic patients. The pre tested questions were used to determine the level of dental caries incidence being after diagnosed with diabetes and also their frequent dental checkups. The question also focuses about their oral hygiene activity

The clinical examination included an evaluation of dental caries, by using dental mirror and dental probe under light source. The dental caries was assessed using the decayed missing filled teeth (DMFT) Index according to the criteria and recommendations of the Klein, Palmer, Knutson 1938.

Result

The following datas were obtained and analysed from 64 males and 56 females,

Table 1: shows the demographic distribution of diabetic patients according to age and Gender.

AGE GROUP (YEARS)	MALE		FEMALE		TOTAL	PERCENTAGE
	n	%	n	%	N	%
35 – 44	8	6.7	3	2.5	11	9.2
45 – 54	12	10	17	14.1	29	24.1
55 – 64	23	19.1	21	17.5	44	36.7
65 – 74	21	17.5	15	12.5	36	30
TOTAL	64	53.3	56	46.6	120	100

Table 2: shows the mean value of DMF(T) score among male diabetic patients

Age group	No. of subjects	Mean DMF(T) value < 2.9	Mean DMF(T) value >2.9
35 – 44	8	2.2	-
45 – 54	12	2.8	-
55 – 64	23	-	3.3
65 – 74	21	-	3.9

Table: 3 shows the mean value of DMF(T) among female diabetic patients.

Age group	No. Of subjects	Mean DMF(T) value < 2.9	Mean DMF(T) value >2.9
35 – 44	3	2.8	-
45 – 54	17	-	3
55 – 64	21	-	3.2
65 – 74	15	-	3.6

Table :4 shows the oral health behaviour and medical characteristic for diabetic patients.

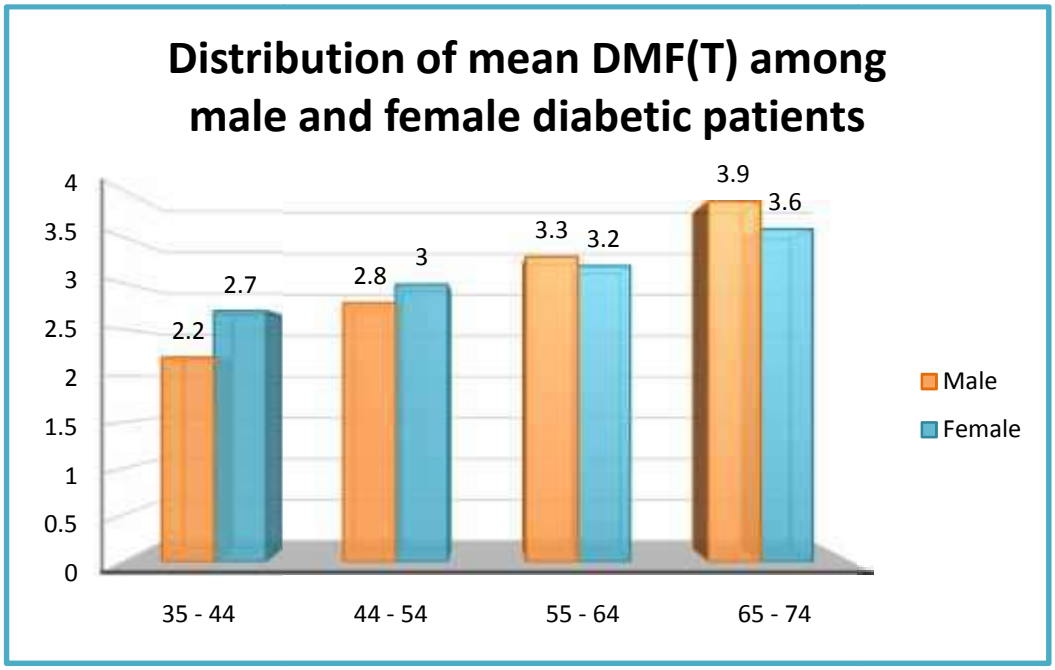
Question	No. of responses	Percentage (%)
Tooth brushing frequency		
Once in a day	87	72.5
Twice a day	24	20
More than twice	9	7.5
Oral cleaning method		
Tooth brush and paste	87	72.5
Tooth brush and powder	21	17.5
Other (finger, charcoal powder)	12	10
Disease duration		
< 5 years	18	15
5 – 10 years	72	60
> 10 years	30	25
Regular dental visit		
6 month once	47	39.1
1 year once	54	45
More frequently	19	15

Graph 1: Responses among diabetic patients

	Familial diabetic	Previous Dental checkup	Extraction due to dental caries	Dry mouth sensation	Poor healing experience
Yes	87	79	63	49	31
No	33	41	57	71	89

Graph 1 shows the responses among diabetic patients about their previous dental check-up, known familial diabetic, extraction due to dental caries, experience in poor healing of tissues and dry mouth sensation.63 subject experienced extraction due to dental caries after being diagnosed with diabetes and 31 subject experienced poor healing of oral tissues. 49 subject experienced dry mouth sensations. 79 subjects have gone for regular dental check up after being with diabetes. 87 subjects have been known familial diabete

Graph 2: shows the distribution of mean DMFT among male and female diabetic patients



Graph 2 shows the distribution of mean DMFT among the male and female diabetic patients.The mean DMFT value for male was 2.2 for age group 35 – 44 and 2.8 for 45 – 54 and 3.3 for 55 – 64 and 3.9 for 65 –74. The mean DMFT value for female was 2.7 for age group 35 – 44 and 3 for 45– 54 and 3.2 for 55 – 64 and 3 for 65 – 74. The mean DMFT score for male and female increases according to their age group.

Discussion

Dental caries is caused by demineralization that is triggered by the accumulation of microbial plaque flora, decrease in the flow rate of saliva causing reduction in the cleansing, and buffer activity and diminished levels of calcium that is essential for the repair of decayed tooth [10]. Dental caries is the most prevalent infectious disease in humans, that commonly affects people of all ages throughout their lifetime. Diabetes is a chronic disease that may impact on personal behaviour. Increasing prevalence of diabetes in the population has made it an important public health issue. The prevalence of dental caries and its burden on the general population is of significant public health interest since dental caries is the most common infectious disease known to man [11].Low fluoride exposure, increase frequency of taking sugary food and soft drinks and observed xerostomia were the prominent reasons being

reported behind this increased risk for caries [12]. According to World Health Organization (WHO), DM has been increasing worldwide so abruptly that it is declared as an epidemic [13].

The present study found that the demographic distribution of study subjects in which female 56 study subjects were more prone to dental caries when comparing to 64 male study subjects due to their oral health activity.

The study found that the mean DMFT values were found to be greater among female study subjects when comparing to male study subjects which is greater than 2.9 was found in 45 – 54, 55 – 64, 65 – 74 age groupand most of the study subjects were known diabetic for 5 – 10 years.

The result of the oral health behaviour questionnaire showed better oral health habits regarding brushing frequency among the diabetic patients and frequency of the tooth brushing, this result agreed with other study that was showed in Almas K et al in (2001),[14] while the other result showed the diabetics were somewhat less likely to visit their dentists for routine examination Pohjamo L et al (1995),[15].

The result of the distribution of the dental caries for both groups according to the age showed the mean values of DMFT Index were increased when the age increased with strong correlation this result agreed with Moore PA et al. 2001[16], reported high caries prevalence among older diabetics patients. And also found that female diabetic patients are more prone to dental caries with increase in age.

People with diabetes appear to have contributing factors that results in increased risk for dental caries [17]. In addition, people with diabetes has a high chances of developing abscess from dental caries. People are less informed the risk for dental diseases in comparison with their knowledge of their increased risk for systemic diseases in DM. Thus, it is necessary for dental professionals and related government medical agencies to promote awareness of the relationship between DM and oral heath to prevent harmful complications[18]. Studies have found that patients with diabetes are more susceptible to increase their risk for developing new and recurrent dental caries [19].

Conclusion

The present study confirmed that the presence of dental caries was not significantly elevated in diabetic patients, but it increased with age. And also found that female diabetic patients are more prone to dental caries with increase in age.Furthermore the diabetic patients reqires improvement in their general and oral health behaviour.

Dental Caries Related Quality of Life and Socioeconomic Status of Adult Population In Perambur, Chennai

S. Rohini[1], Nabeel Nazar[2]
Graduate Student[1], Reader[2], Department of Oral and Maxillofacial Surgery
Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Oral health has a major role in the general well-being of a person. Oral health problems can have wider social, economic and psychological concerns thereby affecting the quality of life. Oral Health Related Quality of Life indicates an individual's perception of how their well being and quality of life is influenced by oral health. The aim of the study is to o determine the oral health related quality of life and the association between dental caries socioeconomic status of adult population in perambur, Chennai.

Material and Methods: The study sample consists of 200 adults and a questionnaire comprised of 10 questions related to oral habits and Kuppuswamy scale (modified for year 2015) to evaluate oral health related quality of life & socioeconomic status of adults in Chennai.

Result: The oral health of an individual and their socioeconomic status was analyzed and found that upper middle class females were commonly affected with dental caries than other class females. The most commonly affected tooth with dental caries was upper right 1stmolar followed by lower left and right 1st molar.

Conclusion: This study showed that there is a strong relationship between the socioeconomic status and oral health. The main purpose of this study is to highlight the importance of assessing oral health related quality of life in the clinical practice so that the clinicians can easily identify the actual difficulties faced by the patients due to oral problems and formulate appropriate treatment plan and goals

Key Words: *Dental caries, Kuppuswamy scale, Oral health, Quality of life,socioeconomic status.*

Introduction

Dental caries is a multifactorial infectious diseasethoroughout the world leading to pain, chewing difficulties, speech problems, general health disorders, psychological problems, and lower quality of life. The prevalence and incidence of dental caries in a population is influenced by a number of risk factor such as sex, age, socioeconomic status, dietary patterns, oral hygiene habits, salivary immunoglobulins, bacterial load and fluoride intake. Dietplays an important role in the development of dental caries. Many previous studies showed that the consumption of foods with high carbohydrate content constitutes an important risk factor for the development of dental caries. Frequency of sugar intake increases the risk for caries development.[1]

Oral health is a state in which the oral tissues contribute positively to an individual's wellbeing in all dimensions of health allowing them to eat, speak and socialise with others without any discomfort. Thus oral health has an important role in the general wellbeing of a person.[2]Oral health problems have been increasingly recognised as important factors causing a negative impact on daily performance & quality of life.

Oral health problems have wider social, economic& psychological concerns thereby affecting the quality of life. Oral health related quality of life denotes a person's perception/concern of how oral health influences life quality and overall wellbeing. It comprises of individual's satisfaction with oral health, self-esteem and the ability to eat, speak & engage in social interactions.

Socioeconomic status (SES) refers to the placement of persons, families, households and census tracts or other aggregates with respect to the capacity to create or consume goods that are valued in our society.[3]Indicators of socioeconomic status (SES), such as household income or education level, are important factors that have an impact on oral health. Several reports have shown that low socioeconomic status groups exhibited worse oral health and a higher prevalenceof caries compared with high socioeconomic status groups. To reduce these

socioeconomic inequalities, many countries have endeavoured to improve the oral health of their citizens through health promotion programs, such as public health campaigns promoting brushing with fluoride toothpaste, school programs of rinsing with fluoride solution, and water fluoridation.

Low socioeconomic status, low monthly household income and low educational level are associated with less access to dental services and oral hygiene products, poorer knowledge regarding oral health and oral hygiene and, consequently, a greater frequency and severity of dental caries

Problems like tooth decay, pulpitis and periodontitis causes pain. Loss of tooth structure can interfere with proper chewing, speaking & aesthetic appearance. Craniofacial disorders, malocclusion, appearance of teeth or denture significantly affect self-esteem, social relationships and communication capability. [4]Hence these problems cause considerable distress to individuals and affecting their quality of life. The association between social & economic status and dental caries prevalence has been evaluated in this study using indices among adult population in perambur alone.

Materials and Methods

The study sample consists of 200 adults and the DMFT (decayed, missing due to caries, filled teeth) index was adopted for assessment of dental caries in accordance with the standards recommended by the world health organisation (WHO).

A questionnaire comprised of 10 questions related to oral habits and Kuppuswamy scale (modified for year 2015) to evaluate oral health related quality of life & socioeconomic status of adults in Chennai. The data was analysed and results were tabulated.

Results

The study was conducted among 200 adults, in which females were dominant than males and in the age group of 34-44 years. Majority of them were graduate and post graduate. From the study it was observed that majority of the adults cleaned their teeth with tooth brush and paste once daily and visited dental office in 6 months for regular dental check up. Most of them also had previous experience of tooth ache due to dental caries and difficulty in consuming hot and cold food items. The oral health of an individual and their socioeconomic status was

analyzed and found that upper middle class females were commonly affected with dental caries than other class females. The most commonly affected tooth with dental caries was upper right 1stmolar followed by lower left and right 1 st molar.

The relationship between the prevalence of dental caries and occupation of the adults were assessed. The unemployed adults were commonly affected with dental caries than any other profession. Thus occupation and socioeconomic status of the subjects had a greater impact on prevalence of dental caries.

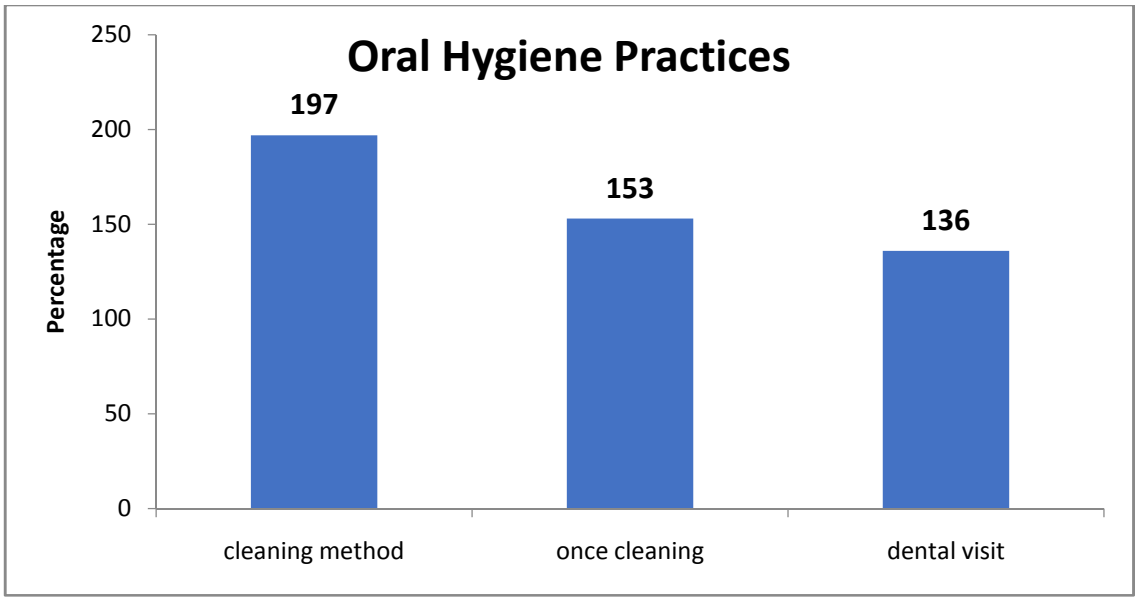

Figure: 1 It shows that majority of the adults cleans their teeth with tooth brush and paste once daily and visits dental office once in 6 months.

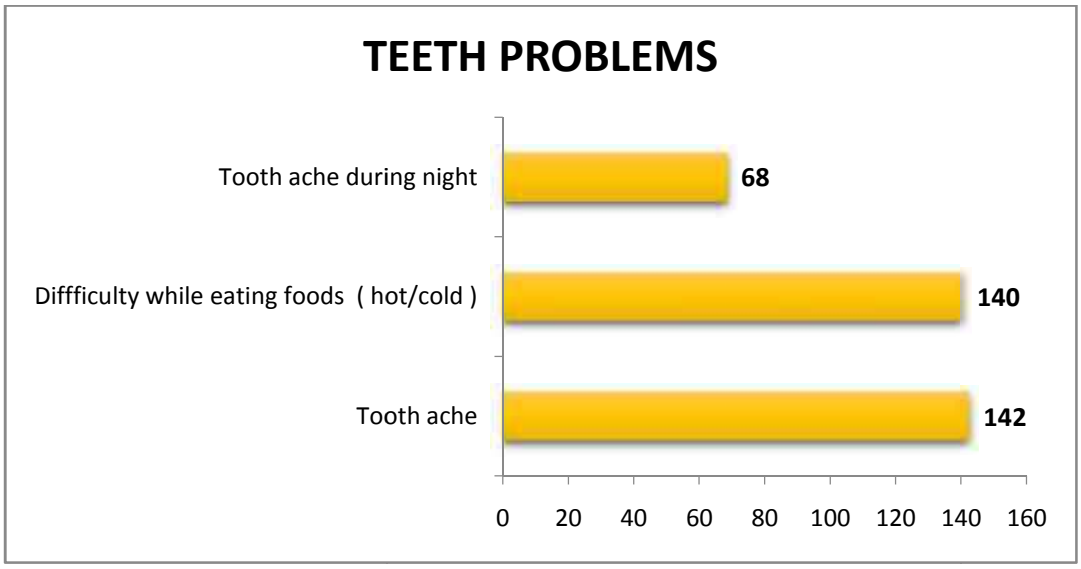

Figure: 2 It shows that majority of adults had previously experienced tooth ache due to dental caries and had difficulty while eating hot or cold foods and tooth ache during night.

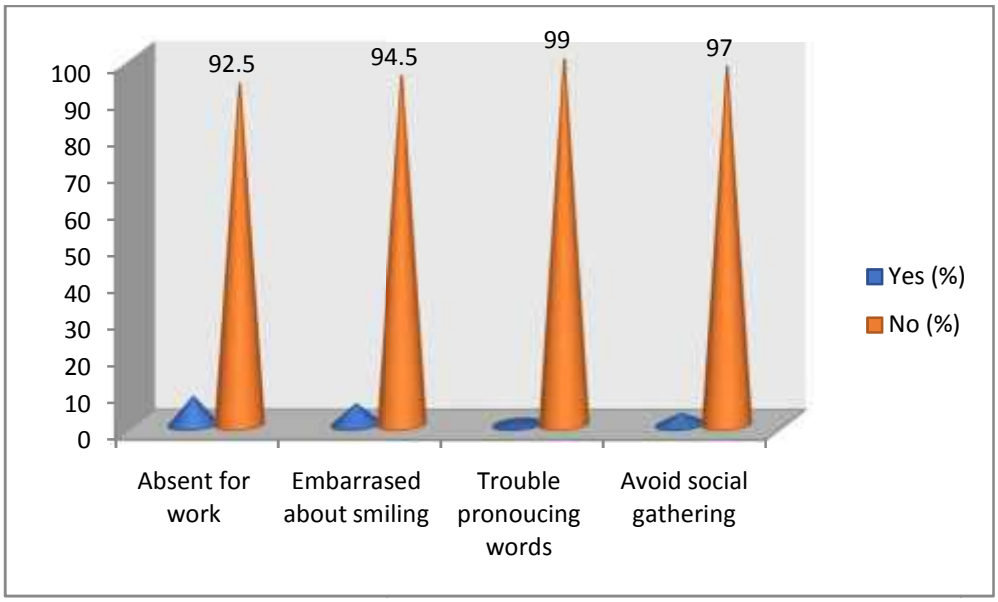

Figure: 3 Oral health related quality of life

Fig: 3 It shows that oral health of the adults and their socioeconomic status didn't have any significant effect on their quality of life like trouble in pronouncing words (99%), avoidance of social gathering (97%), Embarrassed about smiling (94.5%), and absent for work (92.5%).

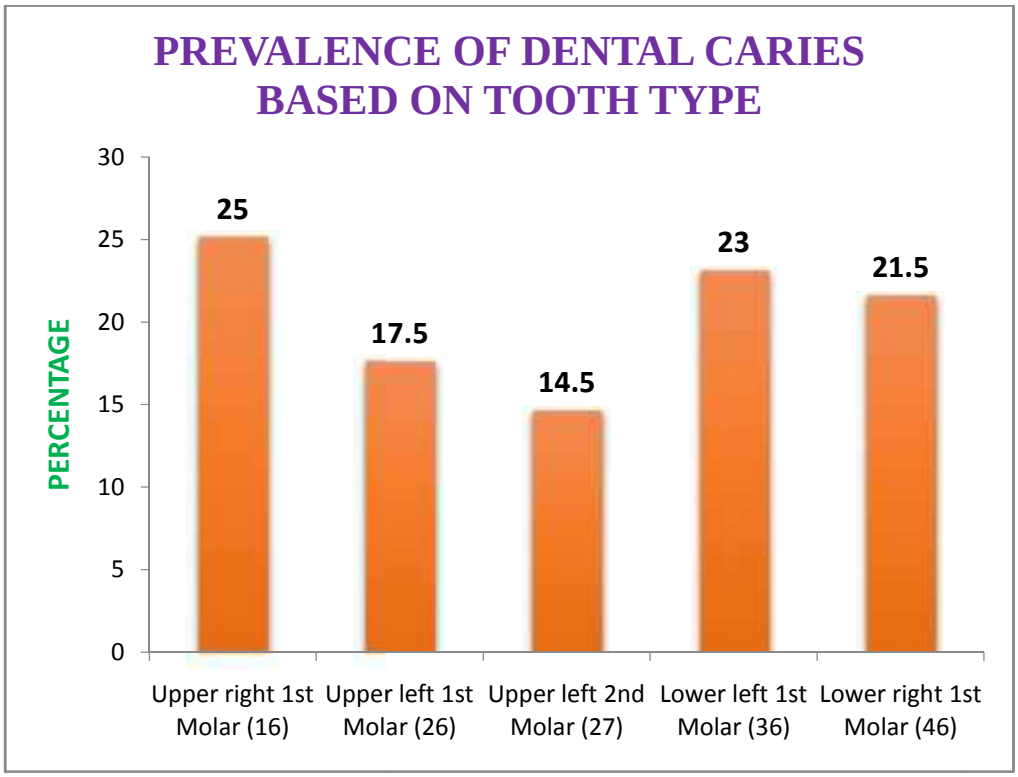

Figure: 4 It shows that upper right 1st molar (25%) was most commonly affected by dental caries, followed by lower left 1st molar (23%) and lower right 1st molar (21.5%).

Table: 1 Demographic Distribution Of Subjects

AGE GROUP (yrs)	FEMALE		MALE		TOTAL	
	n	%	n	%	n	%
<25	17	8.5	13	6.5	30	15

Table: 2 It shows education status of the subjects and majority of them were graduate/ post graduate (49%), followed by high school (21%)

Table: 3 Mean Value Of Dmft Score And Occupation Of Subjects

OCCUPATION	<2.9		>2.9		TOTAL	
	n	%	n	%	n	%
Clerical/shop owner	17	8.5	6	3	23	11.5
Profession	12	6	25	12.5	37	18.5
Semi profession	13	6.5	12	6	25	12.5
Semi-skilled worker	18	9	11	5.5	29	14.5
Skilled worker	17	8.5	21	10.5	38	19
Unemployed	22	1	22	11	44	22

Unskilled worker	4	2	0	0	4	2
TOTAL	103	51.5	97	48	200	100

Table: 3 It shows the relationship between the prevalence of dental caries and occupation of subjects. Unemployed adults (22%) were commonly affected by dental caries than any other profession.

Table: 4 Socioeconomic Statuses And Mean Value Of Dmft Score

SOCIOECONOMIC STATUS	<2.9		>2.9		TOTAL	
	n	%	n	%	n	%
Upper (I)	5	2.5	2	1	7	3.5
Upper middle (II)	37	18.5	41	20.5	78	39
Lower middle (III)	27	13.5	22	11	49	24.5
Upper lower (IV)	28	14	29	14.5	57	28.5
Lower (V)	6	3	3	1.5	9	4.5
TOTAL	103	51.5	97	48.5	200	100

Table: 4 It shows the relationship between the socioeconomic status and prevalence of dental caries. It is shown that upper middle (II) class (39%) adults were more commonly affected by dental caries than other classes.

Table: 5 Mean Value Of Dmft Score Among Gender

GENDER	<2.9		>2.9		TOTAL	
	n	%	n	%	n	%
Male	51	25.5	52	26	103	51.5
Female	52	26	45	22.5	97	48.5
TOTAL	103	51.5	97	48.5	200	100

This table shows that females (51.5%) were more commonly affected by dental caries than males (48.5%).

Discussion

Oral health and the lifestyle of an individual influences the oral health related quality of life. To evaluate the prevalence and severity of dental caries according to WHO recommendations, this study used DMFT score. The study included 200 adults from perambur region in Chennai, among which 103 were females and 97 were males between the age group of 18 to 85 years. In the present study, it was observed that females (51.5%) were more commonly affected by dental caries than males (48.5%) (Table: 5) This result was similar to the studies done by Lawrence et al [5]& Navin ingle.[6]

Occupation of an individual also has an influence on the prevalence of dental caries. In this study unemployment (22%) was associated with higher incidence of dental caries than other occupations like clerical/shop owner, profession, semi profession, etc. (table: 3) The second most common occupation associated with incidence of dental caries was skilled workers (19%).[7]

The association between oral health & socioeconomic status of adults has been well established in this study using Kuppuswamy scale. The upper middle class (II) was found to be more prone to dental caries (39%) than other classes. (Table: 4) This high rate of dental caries is due to their rich lifestyle. This result was different from the study done by Jain R et al[8]& Deva Priya Appukuttan et al in 2016,[8,9]which showed more prevalence of dental caries in lower socioeconomic status. The prevalence of dental caries was high in the low socioeconomic status because of their poor oral hygiene practice, lack of awareness, improper food intake and family status.[10]According to study done Evans et al.,[11] low family income may affect food selection and nutrient intake by mothers and also infants during the tooth development period. It may also affect the degree of education, health values, life-style and access to health care information. As a consequence, family income can be an indirect factor for tooth susceptibility to caries.[12]It is also possible that mothers completing higher levels of education are more responsible regarding health,more likely to maintain good dietary and hygiene behaviours, and are likely to have more positive health attitudes. Moreover, the widespread belief that primary teeth are temporary and not as important as permanent teeth is likely to be higher among mothers with low levels of education.[13]The

recognition that maternal education is a strong determinant of childhood caries confirms that oral health cannot be achieved without educational policies in developing countries. Such programmes may have an impact on the health of infants and preschoolers, including dental caries.

The prevalence of dental caries based on tooth type was also evaluated in this present study. From the study, it was observed that the upper right 1st molar (16) was more commonly affected by dental caries (25%) than other teeth. (Fig: 4) [14]In general terms, the canines and incisors demonstrated fewer dental caries. From the anatomical point of view, such occurrences have been attributed to the anatomical oral position of the teeth, making them accessible to fluoride exposure and hygienic habits. Caries is much more frequent in sites of food retention and bacteria accumulation. Forty to fifty percent of the cavities are normally found on the grooves and cracks of occlusal molar surfaces.[15]

In a study by Li et al.[16]showed that the permanent teeth, particularly the first and second molars are more susceptible to cracks formation, making the adhesion and colonization of cariogenic microorganisms possible. As a result, the dental caries on the occlusal surface are higher than on other surfaces.[17]Naturally, any alteration in oral habits such as oral hygiene, topical fluoride exposure and changes in dietary habits will influence the cariogenic indices in any of the socioeconomic population categories.[18,19]

Oral hygiene practices, teeth problems & oral health related quality of life were also evaluated in this study and found that majority of adults cleaned their teeth with tooth brush (98.5%), once daily (76.5%) and visited dental office once in 6 months (68%). (Fig: 1)[20,21] Among teeth problems, tooth ache (71%) was most commonly experienced by all adults but tooth ache during night (34%) was least experienced by them. It was also found that oral health had least effect on oral health related quality of life.(Fig: 2)[22]Individuals didn't face any trouble in pronouncing words, embarrass about smiling nor avoid any social & peer gathering because of their oral health problems. (Fig: 3) [23]Adults who visit dentist regularly have better oral health status and better oral health related quality of life, requiring less emergency treatment.[24]

Conclusion

This study showed that there is a strong relationship between the socioeconomic status and oral health. The main purpose of this study is to highlight the importance of assessing oral health related quality of life in the clinical practice so that the clinicians can easily identify

the actual difficulties faced by the patients due to oral problems and formulate appropriate treatment plan and goals. [25]

Dental Experience, Anxiety, and Oral Health in Low-Income Chennai Children

S.Thaminee[1],Ganesh[2],V.Ashok[3],
Graduate Student[1],Reader[2], Department of Pedodontics, Reader[3],Department of Prosthodontics,
Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences,Saveetha University, Chennai, India

Abstract

Introduction: Dental problems are more common in children now a days due to the change in food habits.Various treatment modalities are available including fillings,root canal treatment and crown.The ambience in the dental clinic and the noise created by the compressor,suction apparatus makes the child apprehensive,low income children have more exposure to noises and their fear threshold are more compared with high income children.This study was to evaluate the prevalence of dental anxiety and the factors influencing dental anxietyand poor oral health among the low-income children in Chennai.

Materials and Methods: One hundred and fifty children were examined who reported to Pedodontic Department in Saveetha Dental College,chennai. Oral healthstatus of Male and female patientwere assessed based on the decayed, filled teeth index, simplified oral hygiene index, and Streptococcus mutansscore.The assessment excluded patient had Facial deformities,andmentally retardant,suffering from congenital diseases.Dental anxiety was assessed using the facialimage scale and Frankl scale. Early dentalexperience wasclassifiedas: no previous dental visits; preventive control; restorative treatment; and emergency visit.

Result: Dental caries is the key factor for the child to visit the dental clinic.The dental setup and its factors are one of the triggering agent to child's anxious and the previous dental experiences. Patients with systemic problems have high rate of dental caries.

Conclusion: In low income children, Prior dental experiences of six-year-old children were directly related to their dental caries experience. Children who had preventive visits and those

who had never seen a dentist before had low rates of dental caries.Patients have low percentage of dental visit for their preventive treatment due to unawareness of their parents. Simplified oral hygiene index and dental anxiety levels showed no statistically significant differences among the types of previous dental experiences.

Key Words:*Dental caries,Anxiety,Oral health,Dental experience,Fear,Preventive treatment,Low-Income*

Introduction

Dental caries is the most common chronic disease of childhood and is, therefore, of great importance to public health. Dental caries is the key factor for the child to visit the dental clinic.The dental setup and its factors are one of the triggering agent to child's anxious and the previous dental experiences(17,18).

Patients with systemic problems have high rate of dental caries.Anxiety and fear towards dental treatment are common problems frequently experienced by patients worldwide, hence for better understanding, management and development of treatment strategies for dentally anxious patients,and their dental experience and oral health the present study was undertaken(1).

The study aimed to evaluate the prevalence of dental anxiety and the factors influencing dental anxiety,poor oral health among the Low-income children in Chennaiand is about the anxious and experience of the child in dental clinic and how their anxious makes the treatment complicated and the background of their anxious is dental caries(19).The severity of dental caries measured by the decayed, missing,filling teeth and OHI-(S) index(2).

Materials and Methods

One hundred and fifty children were examined under Indusian criteria both female and Male.A sample of 150 questionnairewere circulated containing 15 questions. Oral healthstatus were assessed based on the decayed, extracted, or filled teeth index, simplified oral hygiene index, and Streptococcus mutans score. Dental anxiety was assessed using the facial imagescale andFrankl scale. Earlydentalexperience was classifiedas: no previous dental visits; preventive control; restorative treatment; and emergency visit(20).

Questionnaire

Dental Experience, Anxiety, and Oral Health In Low-Income Chennai Children

Name: **Sex:Male/Female**

Age:

Socioeconomic Status: A)<25,000/Year ,B)25,000-50,000/Year,

C)50,000-1,00,000/Year

Questions:

1)Does your child had any previous dental visit?

A)Yes

B)No

2)How was the child's experience for the first dental visit?

A)Pleasant

B)Fair

C)Poor

D)Unpleasant

3)Does the child is anxious to any of the dental set up?

A)Yes

B)No

If YES –To what:

4)Does your child had any treatment on his/her first dental visit?

A)Yes

B)No

C)Emergency

5)Does your child has any forward looking to the dentist after their first dental visit?

A)Yes

B)No-Why?

6)How was your child's oral health before visiting a dentist?

A)Excellent

B)Good

C)Fair

D)Poor

7)What's your child's daily frequency of brushing?

A)Once

B)Twice

8)Does your child brushes their teeth on their own?

A)Yes

B)No

9)What kind of snacks Does your child take often?

A)Chocolate/sweets

B)Beverages

C)Ice cream

10)Have your child had any preventive treatment for dental caries?

A)Yes

B)No

11)How was the child's behaviour during the dental procedure?

A)Uncooperative

B)Cooperative

12)Are you aware of the preventive treatment for your child's dental caries?

A)Yes-How?

B)No

13)Does your child has any systemic problems?

A)Malnutrition

B)Communicable disease

C)Infectious disease

D)Congenital disease

E)Learning /Speech difficulties

F)Growth retardation

14)What's the rate of caries in children undergoing restorative and emergency treatment?

A)<2

B)2-5

C)>5

15)Oral health assessment:

A)OHI-S:

B)DMFT/S: Decay- Missing- Filling-

Discussion

This study aimed to assess the relationship between early dental experience and clinical/microbiological indicators of oral health status and dental anxiety at the time of admission to a dental clinic for oral health assessmentof the children. Few children who visited to dental clinic due to emergency visit had a dmft/S index of zero. The emergency in these cases was most likely not related to dental caries but to other causes, such as dental trauma. The preventive controlhad a significantly lower prevalence of caries and comprised

the highest percentage of children without caries. The oral health assessment showed that the child underwent restorative treatmentand emergency visit to dental clinichad a higher caries risk than child had preventive control treatmentand no prior dental visit groups.Our results are consistent with those of Wennhall et al.,who showed that an early start in oral health programs has significant benefit in the prevention of caries and that the more children attend dental exams, the lower the incidence of caries. In this study, children attending the dentist for the first time at six years of age did not exhibit significant differences in dmft/S scores compared to children who had previous preventive treatment. However, there was a significantdifferencein the caries component, with higher values for the Non-Visitors to dental clinic than children whom already had preventive treatment group. Therefore, while the values for the dmft/S index were similar, children who never had a dental visit had poorer oral health than children who attended Preventive treatment highlighting its importance. AnniLuoto et al.,(14) in which associations between Child Perceptions Questionnaire and dental fear were not statistically significant. This may be due to the fact that non-school going children are mainly street children, and among them there is a false impression that dentistry is mainly involved with extraction and is a painful procedure that may be further complicated by wide range of health problems, including malnutrition, communicable and infectious disease, poor oral health, cognitive disorders and learning difficulty(15). The study showed that subjects who rated their oral health as poor had higher levels of dental anxiety than those subjects who rated their oral health as good or average, this was in accordance with the findings by Locker and Liddell(4), Doerr et al.(7). Contrary to the findings of Erten et al.(8), Skaret et al.(9), Hagglin et al(10)the results from the present study showed no significantdifference in dental attendance based on anxiety level and this was similar to the reports from Indian studies by Acharya(3), EktaMalvaniaandAjithrishnan(11) but contrary to the findings of Pavi et al. (12), Stole et al. (13). The relationship between dental anxiety and socio economic status has not been clearly determined. In this study uneducated patients and patients with less or no income had no knowledge about their child's dental caries preventive treatment; this is in accordance with other studies [5,6].

Conclusion

Based on the results of this study, the following conclusion can be made

1. Prior dental experiences of six-year-old children were directly related to their dental caries experience.

2. Children who had preventive visits and those who had never seen a dentist before had low rates of dental caries.

3. Patients have low percentage of dental visit for their preventive treatment due to unawareness of their parents.

4. Simplified oral hygiene index and dental anxiety levels showed no statistically significant differences among the types of previous dental experiences.

Dental anxiety refers to the fear going to the dentists. It exists in a considerable number of children and it is a major plight and concern in pediatric dental practice(16).

Difficulties Encountered by the Dental Students during Transition from Preclinical to Clinical Endodontics – A Questionnaire Study

Bhavani Ganesan[1], Sandhya Raghu[2], Jaiganesh Ramamurthy[3]

Graduate Student[1], Reader[2], Department Of Conservative And Endodontics, Reader[3], Department Of Periodontics

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Feedback from the students is beneficial to review the curriculum and improve the standard of training.Endodontic treatment can be one of the most difficult dental procedures a student encounters during preclinical and clinical practice. Research on the difficulties of endodontic procedure performed in preclinical and clinical years are limited. Hence this study had been planned to analyse the difficulties.The aim of the study was to analyse the difficulties encountered by the dental students during transition from preclinical to clinical endodontics.

Materials and Methods: The questionnaires were distributed to 100 students including third year, final years and house surgeons pursuing under graduate program in dental surgery. The questions were focused on experiences during each step of root canal procedure including rubber dam placement, access related difficulties, difficulties during working length determination, shaping and cleaning and obturation. The data were analyzed to achieve the results.

Results: Most of the students reported that they had difficulty in rubber dam application in preclinical than clinical endodontics. Most of the students reported that reaching the pulp chamber or locating the orifices was much easier in preclinical procedure than clinical procedure. Students also reported that difficulties encountered during cleaning and shaping was more in clinical procedure. Time taken to adapt with the usage of magnifying loupes and rubber dam placement were the major concern of the students. Regarding incidents of instrument distortion in the form of bending, instrument separation, at pre-clinical stage: 57% said they never has such incidents, 24% said sometimes they encountered instrument

distortion, 19% said they had frequent incidents of instrument distortion. Whereas at clinical stage, 64% said they never had such incidents, 27% said sometimes they had instrument distortion, 9% said they had frequent incidents of instrument distortion.

Conclusion: This study suggested that students have better practice in endodontic procedure.By identifying the problems encountered by the students at the right time could help them overcome the clinical difficulties during endodontic procedures. This in turn would reduce procedural time and increases the success of the treatment.

Key Words: *Dental Students, Endodontics, Pre –Clinical, Obturation, Dental Procedures.*

Introduction

Theoretical and practical knowledge is taught to dental students in their dental course. The quality of guidance can be analysed by taking the students perceptions into consideration. Feedback from the students is beneficial to review the curriculum and improve the standard of training. [1]Endodontic treatment can be one of the most difficult dental procedures a student encounters during preclinical and clinical practice. Research on the difficulties of endodontic procedure performed in preclinical and clinical years are limited. [2]

Due to the increase life expectancy in the population and the desire of individuals to preserve their natural teeth, there is an increasing demand for endodontic treatment and this will presumably increase in the years ahead. This reality necessitates dental students to be satisfactorily equipped with knowledge as well as experience in endodontic procedures prior to working independently.The aim of the study was to evaluate the difficulties by the dental students during transition from preclinical to clinical endodontics.

Materials and Methods

The questionnaires were distributed to 100 students including third year, final years and house surgeons pursuing under graduate program in dental surgery. Thequestions were focusedon experiences during each step of root canal procedure including rubber dam placement, access related difficulties, difficulties during working length determination, shaping and cleaning and obturation. The data were analyzed to achieve the results.

Table 1:Questionnaire

Year of Studying: BDS - Third year/ Final year/ Intern

PRECLINICAL	**CLINICAL**
1. Did you take time to adapt with the usage on magnifying loupes for pre-clinical endodontic procedure ? a) Yes b) No	Did you take time to adapt with the usage on magnifying loupes for clinical endodontic procedure ? a) Same as the preclinical b) Initial difficulty c) Still having difficulty
2.Did you have difficulty in rubber dam application ? a) Never b) Sometimes c) Frequent	Do you have difficulty in rubber dam application? a) Never b) Sometimes c) Frequent
3.Time taken for the placement of rubber dam? a) Less time b) More time	Time taken for the placement of rubber dam? a) Same as preclinical b) Less than preclinical c) More time than preclinical
4.Did you take a time for clamp selection ? a) Less time b) More time	Do you take a time for clamp selection ? a) Same as preclinical b) Less than preclinical c) More than preclinical
5.Did you have difficulty in reaching the pulp chamber ? a) Never b) Sometimes	Do you have difficulty in reaching the pulp chamber ? a) Never b) Sometimes

c) Frequent	c) Frequent

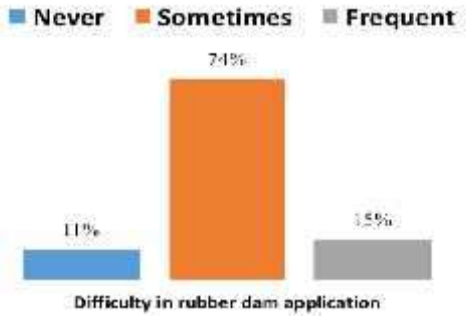
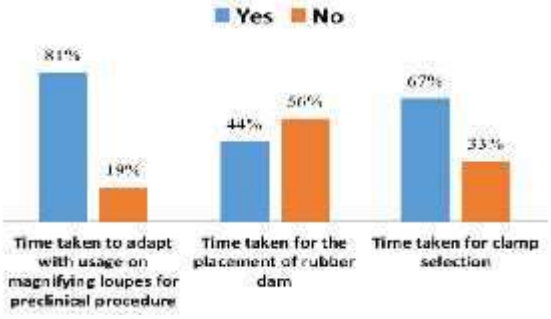
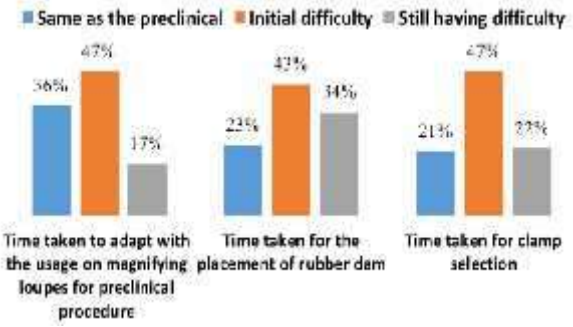


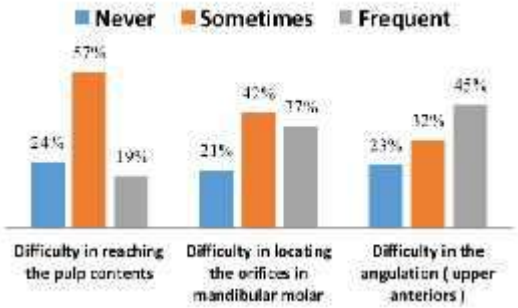
Graph 2: Clinical



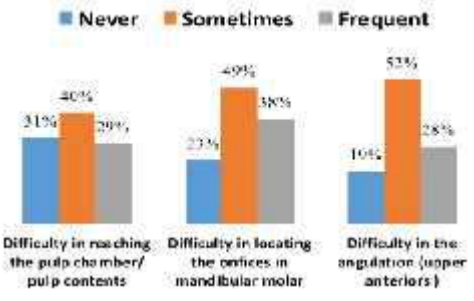
Graph 3: Pre-Clinical



Graph 4: Clinical

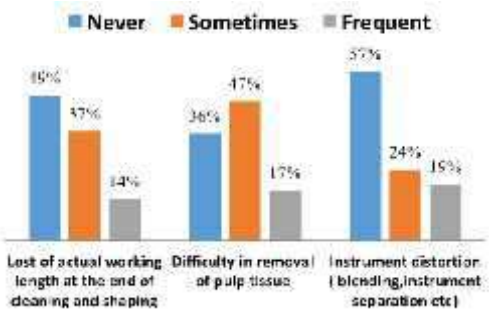


Graph 5: Pre-clinical

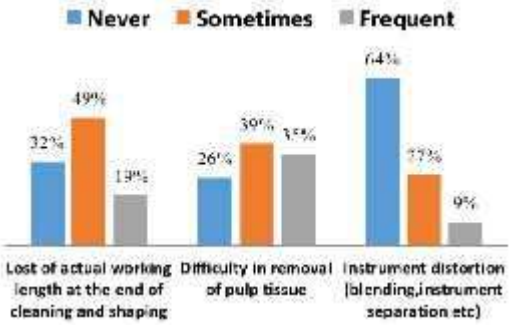


Graph 6: Clinical

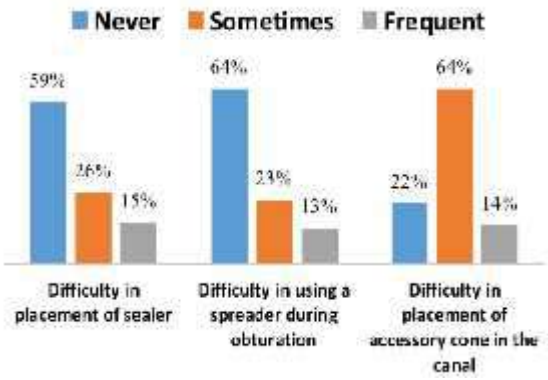
Graph 7: Pre-Clinical



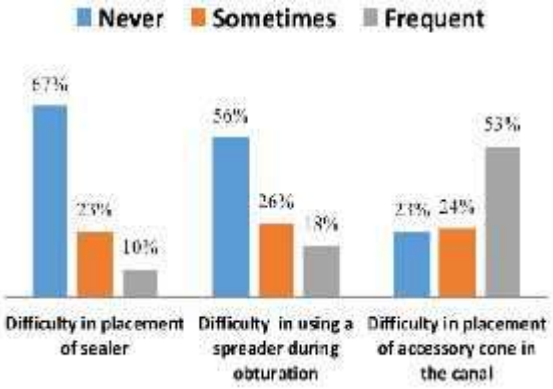
Graph 8: Clinical



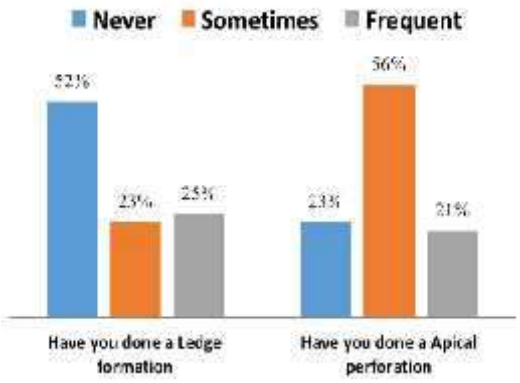
Graph 9: Pre-Clinical



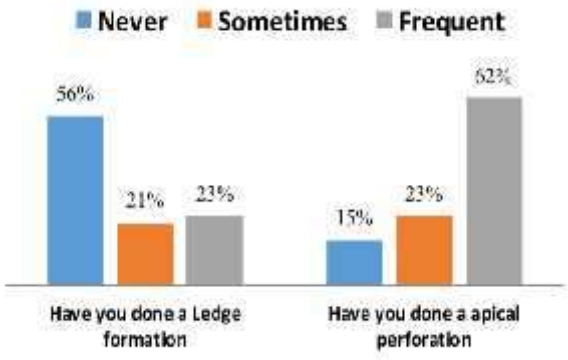
Graph 10: Clinical



Graph 11: Pre-Clinical



Graph 12: Clinical



With respect to difficulty in rubber dam application, during preclinical period 74% of students said sometimes they found it difficult to place the rubber dam, whereas 15% of students said they frequently had the difficulty and 11% said they never faced the difficulty.
In clinics, 48% of the students said sometimes it was difficult placing the rubber dam and 36% said frequently they had problems in placement and 16% said they never had the difficulty.

Regarding time taken to adapt with the usage on magnifying loupes for the procedure, 81% of students said they took long time to adapt and 19% said they were able to adapt quickly for using loupes in pre-clinical procedures. In clinical procedures, 36% of the students said time taken to adapt was similar to pre-clinical procedures and 48% said they had difficulty only in the initial stage and 17% said they are having difficulty even in the current stage and not getting changed. With respect to time taken for rubber dam clamp selection, 67% of the students said they took long time in pre-clinical level and 33% said they were able to select in less time and for students doing clinical procedures, 21% said its same as pre-clinical and 47% had initial difficulty in clamp selection and 22% said they have difficulty in clamp selection even in the present stage.

With respect to difficulty in reaching the pulp chamber and pulp contents, 57% of the students said sometimes they had difficulty in reaching the pulp chamber and 19% said they had frequent problems in reaching the pulp chamber and 24% said they never had problems in reaching the pulp chamber and pulp contents in pre-clinical level. In clinical level, 40% of the students had sometimes difficulty in reaching the pulp chamber and 31% said they never had that difficulty and 29% said they had frequent problems in reaching pulp chamber and pulp contents.

Same way when difficulty in locating the orifices in mandibular molar was analysed, 42% of the students said sometimes they had difficulty in locating the orifices and 37% had difficulty in accessing the orifices frequently and 21% never had difficulty in pre-clinical level and in clinical stage 49% had sometimes difficulty in locating the orifices of molar and 38% said its frequent and 23% said they never had the difficulty.
When asked about the difficulty in angulation for upper anteriors, 45% of the students said they had frequent difficulty in orienting themselves for angulation of the tooth and 32% said

sometimes they faced difficulty and 23% said they never had problems with the angulation in preclinical level. In clinical situations, 28% said they had frequent problems with angulation, 52% said sometimes they had problems and 19% said they never faced any difficulty in orienting themselves for the angulation of the anterior teeth.

When asked about the loss of working length at the end of cleaning and shaping, at the pre-clinical stage, 37% said sometimes they faced the issue and 49% said they never faced it and 14% said frequently they had problems with loss of working length at the end of cleaning and shaping. Whereas at clinical stage, 32% said they never had such an issue and 49% said sometimes they had the issue and 19% said frequently they had problems in loss of working length. When asked about the difficulty in removing pulp tissue, 47% said sometimes, 17% said frequent difficulty in removing the pulp tissue and 36% said they never had any difficulty in preclinical level. In clinical cases, 39% said sometimes they faced the difficulty, 26% said they never had difficulty and 35% said frequently they faced difficulties in removing the pulp tissue.

Regarding incidents of instrument distortion in the form of bending, instrument separation, at pre-clinical stage: 57% said they never has such incidents, 24% said sometimes they encountered instrument distortion, 19% said they had frequent incidents of instrument distortion. Whereas at clinical stage, 64% said they never had such incidents, 27% said sometimes they had instrument distortion, 9% said they had frequent incidents of instrument distortion.

When asked about the difficulty in placement of sealer, at pre-clinical level, 67% said they never faced any difficulty, 23% said sometimes and 10% said frequent difficulty in placement of sealer. In clinical situations, 59% said they never faced difficulty in placing sealer, 26% said sometimes only and 15% said frequent difficulty in placing sealer. When asked about the difficulty in using a spreader during obturation, 56% said they never had the difficulty, 26% said sometimes only and 18% said frequent encounters of difficulty. In clinical situations, 64% said they never had the difficulty, 23% said sometimes only and 13% said frequent episodes of difficulty in placing the spreader.

When asked about the difficulty in placement of accessory cone in the canal, in pre-clinical stage 23% said they never had the difficulty, 24% said sometimes only and 53% said they

had frequently encountered the problem. In clinical situations, 22% never had such instances, 64% said sometimes only and 14% said they had frequent episodes of difficulty in placement of accessory cone.

When asked about the ledge formation during RCT, in pre-clinical stage, 52% said they never had such an issue, 23% said sometimes only and 25% said frequently. With regards to apical perforation, 23% said they never done that, 56% sometimes only and 21% said frequently done apical perforation.

Discussion

Regular evaluation and feedback from students is necessary to improve and to overcome the difficulties. [3-5]Most of the students reported that they had difficulty in rubber dam application in preclinical than clinical endodontics.

Graph shows that time taken to adapt with the usage of magnifying loupes and rubber dam placement were the major concern of the students.Reason for difficulty in usage of magnifying loupes are, they have limitations such as convergent vision, deficient magnification, image distortion, colour alteration, small depth of focus, reduced working field, and fatigue caused by extended use. [6-8]To overcome this problem, choice of correct loupes and appropriate usage is indicated.Patient cooperation is a concern during rubber dam placement which could have been the reason for difficulty in a clinical scenario. [9]

Most of the students reported that reaching the pulp chamber or locating the orifices was much easier in preclinical procedure than clinical procedure.Students also reported that difficulties encountered during cleaning and shaping was more in clinical procedure.The problems with procedural errors can be reduced with the use of appropriate technique. [10-11]To retain the actual working length, recapitulation and proper irrigation is indicated. Instrument distortion can be reduced by avoiding inadvertent use of hand instruments. [12-15]Different methods have been used for locating the position of canal terminus and measuring the working length of root canals. These include radiographic methods, electronic methods, tactile method and other adjunctive methods. [16-20]

Considering obturation related difficulties, placement of accessory cone in the root canal was more difficult in preclinical than clinical endodontics, which can be managed with right

choice of master cone, spreader size and accessory cone. Most of the students reported that they had no difficulty in placement of sealers.

Conclusion

From the results of this study following conclusions can be made:

1.Placement of rubber dam during pre-clinical exercises reduced the difficulty of placement when they do their clinical cases.

2.Usage of magnifying loopes in pre-clinical exercises helped them to adapt themselves for using it in clinical situations.

3.Pre-Clinical exercises reduced the difficulty of reaching the pulp chamber, pulp contents, and teeth angulation when they performed in clinical situations.

4.Better instrument handling with less incidents of instrument distortion like bending, instrument separation occurred when they practiced well in pre- clinical exercises.

5.Efficiency of obturation was increased when the students practices pre-clinical obturation exercises before their clinical cases.

6.Frequency of formation of ledge and perforation significantly reduced when they practiced root canal procedures in pre-clinical stage.

This study suggested that students have better practice in endodontic procedure when they practiced proper pre-clinical training.By identifying the problems encountered by the students at the pre-clinical level itself could help them overcome the clinical difficulties during endodontic procedures.This in turn would reduce procedural time and increases the success of the treatment.

Etiologyfor Tooth Extraction among Individuals of Different Age Groups in Chennai

N. Vidulasri[1], Nithya Jagannathan[2], Caroline Jacob[3],
Graduate Student[1], Reader[2], Department of General Medicine**,**Senior Lecturer[3], Department of Periodontics,
Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction:Dental extractions are often performed when teeth have become challenging to restore as a result of tooth decay, periodontal disease or dental trauma. However, despite advances in dental therapy, individuals hesitate to save teeth thereby prolonging periods of edentulism which if unreplaced may pose difficulties in restoring esthetics and function.
The aim of this study is toextrapolate reasons for tooth extraction among individuals of different age groups in a population in Chennai.

Materials and Methods: A questionnaire surveywasdesigned to evaluate the reasons of extraction which was carried out among 221 patients with 500 tooth extractions having been performed for these individuals forvarying reasons such as periodontitis, dental caries, and trauma, orthodontic, prosthetic and endodontic failures.

Results: 500 extractions performed in 221 patients revealed that 113 (22.6%) teeth extracted was due to dental caries, 186 (37.2%) was extracted due to periodontitis, 94(18.8%) due to orthodontic problems, 75(15%) due to impaction and 32(6.4%) due to other causes.

Conclusion: In this study out of 500 teeth extractions, 186 (37.2%) teeth were extracted due to periodontitis which was also noted to be the major cause for tooth extraction in males over 31 years of age. The next most common cause of tooth extractions were due to teeth affected by dental caries and pulpitis(22.6%).In females,the latter was the major for tooth extraction, followed by periodontitis with the number of extractions increasing in individuals between the age groups 21 to 40 years. Among all age groups the most commonly extracted teeth were the lower posterior teeth.

Key Words:*caries, exfoliated teeth, exodontia, periodontal disease, tooth loss*

Introduction

Loss of teeth has become a major oral health problem worldwide and is attributed to caries, periodontal disease, trauma, impaction and orthodontic problems.The removal of teeth is one of the most commonly performed dento-alveolar procedures in oral and maxillofacial surgery.(1) Studies on tooth mortality can provide valuable information regarding the patterns of oral disease in individual populations.Preventive strategies have to be implemented to minimize tooth loss due to oral diseases.(2)Studies concerning the epidemiology of oral disease has shown that dental caries and periodontal diseases are the most prevalent conditions that affect the oral cavity.(3)Most of these surveys were designed to investigate the etiology, severity and distribution of tooth loss based on the patient demographics and tooth type.(3,4)Dental caries and periodontal disease are the foremost reasons for extraction of permanent teeth(5,6)while extraction due to orthodontic treatmentreplaced caries as the most common reason for extracting teeth in individuals younger than 20 years of age.(6) In cases of trauma, extensive tooth injury may require extraction. Assessment of tooth mortality data in different parts of the world is essential to evaluating the adequacy of dental care and preventive oral health programs.Studies indicatethat populations with poorer socioeconomic conditions have higher prevalence of the condition and extent of teeth mortality, which increases with the age of the individual.(7-9)Prior to the introduction of antibiotic use, chronic tooth infections were frequently associated with a variety of health-related conditions resulting in the removal of such diseased teeth as a common treatment option for such conditions.(10) Understanding the reasons fortooth extracted may improve oral health outcomes.Tooth loss has various harmful effects on an individual which may include the impairment of masticatory function, unpleasant aesthetics, poor phonetics, temporomandibular dysfunctions, psychological issues, social withdrawal and decrease in confidence.(11) The impact of tooth loss also includes decreased function of speech and mastication especially in the elderly.(12,13) Several complications may also occur during extraction of teeth, including damage to adjacent teeth, retained roots, fractured jaws in individuals with osteoporosis and nerve injury during the extraction of mandibulararthird molars. Therefore, the aim of this study was to elucidate the

reasons for the extractions of tooth among different age groups in males and females while analyzing teeth that were most commonly extracted.

Materials and Methods

The present study was undertaken to extrapolate the reasons for tooth extraction in different age groups among aconvenient sample size of 221 patients in a dental hospital in Chennai, India.The reasons for extractions were categorized into caries and pulpitis, periodontal disease, orthodontic problems, impacted teeth and other causes (cysts or tumour of the tooth, prosthetic removal, fractured tooth, supernumerary tooth).Demographic data and information regarding the etiology for tooth extraction was collected and entered in the proforma . The subjects were divided into seven groups from between 0-80years of age which included those belonging to the ages of 0-10 years, 11-20 years,21-30 years,31-40 years,41-50 years,51-60 years, 61-70 years and 71-80years.

The type of the tooth extracted was based on its location which was designated as maxillary anterior, maxillary posterior, mandibular anterior or mandibular posterior.The data was analysed and tabulated for male and female subjects based on the different reasons for tooth extraction. Comparisons between different age groups and commonly extracted tooth among different age groups were also analyzed.

Results

Table1 describes the predominant causes of extraction of the 500 teeth extracted. 113 (22.6%) teeth extracted was due to dental caries, 186 (37.2%) was extracted due to periodontitis, 94(18.8%) due to orthodontic problems, 75(15%) due to impaction and 32(6.4%) due to other causes.

Table1:Etiology for the tooth extraction

Etiology	Total no (n)	%
Caries and pulpitis	113	22.6
Periodontitis	186	37.2
Orthodontic	94	18.8

Impacted	75	15
Others	32	6.4

Table 2: Tooth extraction causes listed by gender and age groups

Etiology	**Females**							
	0-10	11-20	21-30	31-40	41-50	51-60	61-70	71-80

Impacted	0	2	34	2	0	0	0	0
Others	1	1	6	5	4	0	0	0

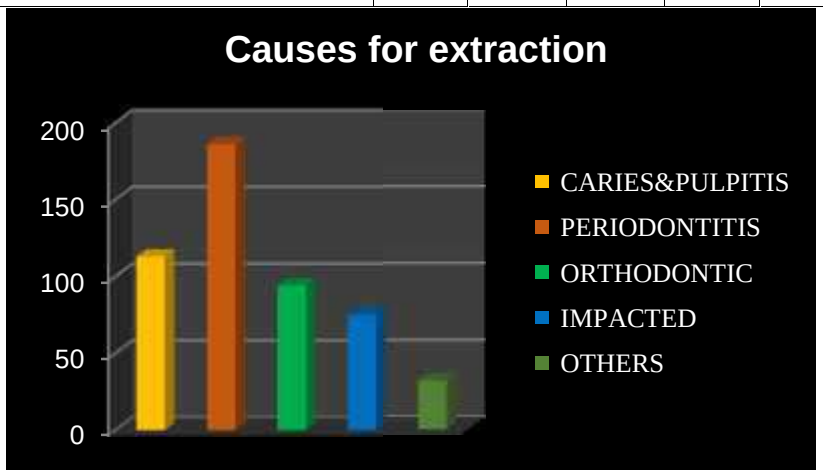

Figure 1: Graph depicting the etiology for tooth extraction

Dental caries and pulpitis were found to be a significant cause for extraction among female patients over 20 years and it was also the most significant cause of extraction for

thecombined age groups of 21-40 years. In addition, periodontitis was the major cause of tooth extraction in males which increased with age and among combined age groups of 31-80 years. In patients ranging between 21-40years,orthodontic problems was found to be a cause for tooth extraction. Impactions were a major cause of tooth loss in patients ranging between the age groups of 21-40 years. Other causes for extraction were equally distributed among all the agegroups.

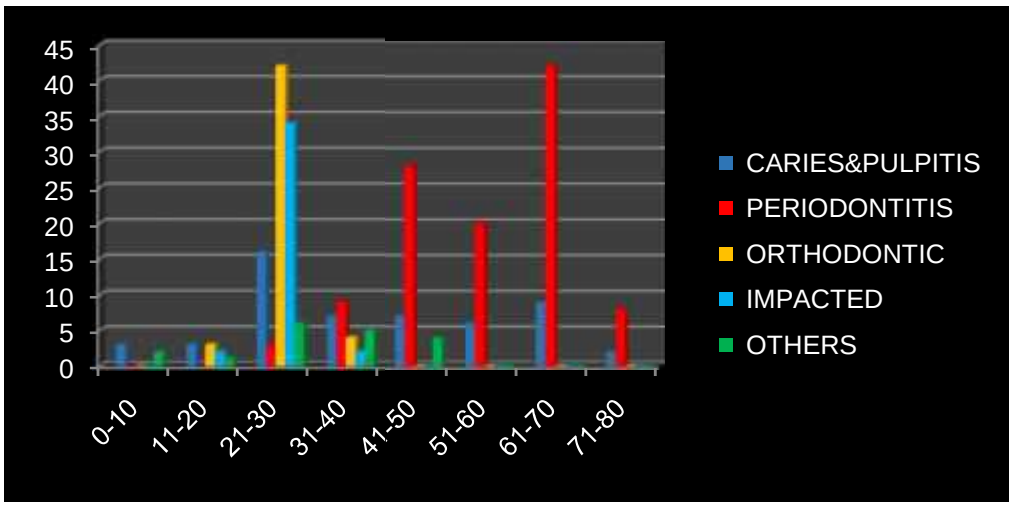

Figure 2: Etiology for tooth extraction in various age groups among males

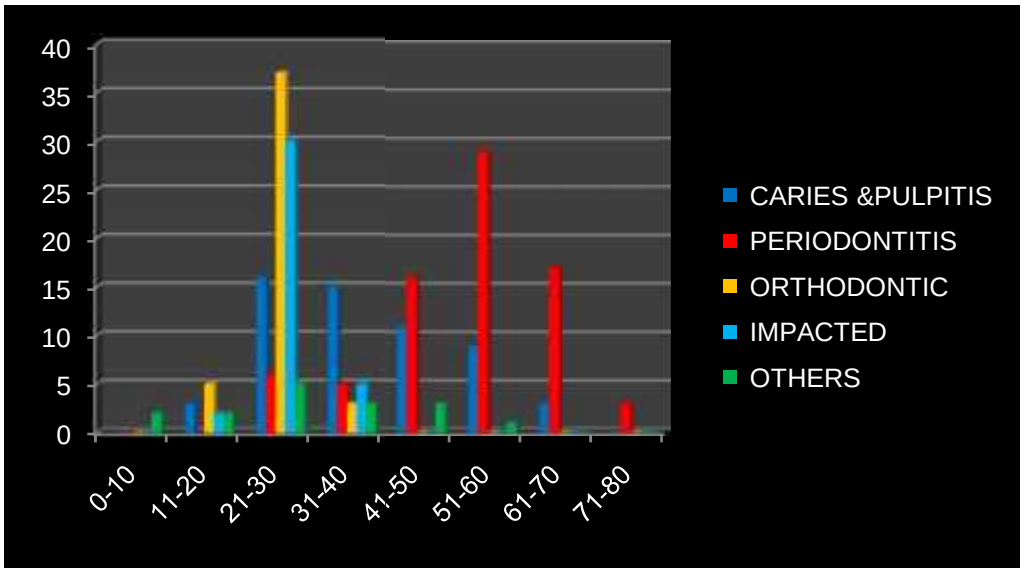

Figure 3: Etiology for tooth extraction among various age groups in females

Table 3:Description of extracted teethcategorized by age and tooth groups

AGE GROUP (Years)	Max.Ant	Max.post	Man.Ant	Man.post
0-10	1	2	1	3
11-20	1	5	0	8
21-30	3	27	0	48
31-40	6	30	4	19
41-50	8	44	19	33
51-60	13	50	12	21
61-70	15	35	16	35
71-80	12	8	6	15

(Max.Ant- Maxillary anteriors, Max.Post- Maxillary posteriors, Man.Ant- Mandibular anteriors, Man.Post- Mandibular posteriors)

Table 3 describes the most commonly extracted tooth type in different age groups. Maxillary posterior teeth were commonly extracted in patients ranging between 31-60 years which was closely followed by mandibular posterior teeth. Between the age group of 61-70 years, both mandibular and maxillary posteriors had the same incidence of extraction. However, among the oldest age group of 71-80 years, mandibular posterior teeth were most frequently extracted followed by maxillary posterior teeth. Maxillary anterior teeth were commonly extracted in the age groups of 51-60 years and 71-80 years while mandibular anterior teeth were most often extracted among patients aged between 41-50 years but was barely appreciable in individuals younger than 30 years of age

Discussion

Tooth loss is the dental equivalent of mortality.The end result of oral disease can reflect both the patient's own attitude to dental hygiene and the availability and accessibility of oral health care.(4)Great variation exists in the frequency and causes of tooth extraction in different countries.(5)Research suggest that the incidence of dental caries and periodontal diseases has progressively increased with the advent and availability of refined sugar in the average diet.(6)In Singapore, a survey of the reasons for tooth extraction showed that the percentage of teeth extracted for periodontal reasons and caries was about the same. In Brazil, 70% of tooth extraction was found to be due to caries, while extraction due to periodontal disease accounted for only 15% of tooth loss.(6,7) Dental practices in southern Wales indicated that caries was the main reason for tooth extraction (59%) in patients attending routine dental treatment while periodontal disease was the second most common reason (29%).(8) A survey performed in Tehran proposed that dental caries and its complications were the leading reason for extraction followed by periodontal.(9) Furthermore, extractionsperformed in male patients were more due to periodontitis have been associated with the deleterious effects oftobacco andarecanut.(10)The current study also suggests that male patients lose more teeth than female patients as a result ofperiodontitis

while female patients lose teeth to both caries and periodontitis. This has been previously discussedas the main causes of tooth loss as the result of such extraction.(11, 12) However, other studies indicate thatperiodontitis is the main reason for extraction of teeth as compared to dental Caries (13). Other results suggest that 62% of extractions of permanent and primary teeth were due to caries, with periodontal disease being the main reason for extraction in patients over 40 years of age(14-16), which was similar to the results in this study. These differences may be attributed to global variances in diet, socio-economic factors, level of dental awareness as well as water fluoridation. This study also showed that posterior teeth were more frequently extracted compared to anteriors which in accordance to previous studies.(17-19)In a study by Daameh et al, incisors were most frequently extracted in older individuals due to periodontitis(20), with mandibularanterior teethbeing most periodontal involvement.(21) In this study incisors were the second most common teeth to be extracted after molars which was due to the effect of periodontitis on those teeth. A more likely reason for the high periodontal extraction in anterior teeth is due to the fact that they are less susceptible to caries, retained for a longer duration in the mouth, and then may be subjected to the risk of periodontal disease(21,22). Maxillary premolars and molars in males were most commonly extracted tooth as a result of periodontal disease, but as was the case for caries, the presence of caries was the main reason for loss of all maxillary teeth in females.(23)The majority of extractions of third molars has been shown to occur in the age group 21–30 years (48.2%), while most of the extracted first premolars (58%) occurred in the age group 10–20 years (24), which was in accordance with this study. This may have been due toimpacted third molars and teeth that had to be extracted for orthodontic treatment especially in patients between the age groups of 21-40 years. Irregular tooth brushing and irregular visits to dentists significantly increased the number of third molar extractions due to caries and periodontal disease compared with those who reported regular tooth brushing and making regular dental visits.(25) Therefore, regular dental visits would be the best way of reducing need for more invasive and uncomfortable proceduressuch as extractions.(26) Studies have also reported that subjects with higher education levels had comparatively fewer tooth extractions than those with incomplete or lower education levels. This relationship is in agreement with other studies in which tooth loss was associated with a low level of education.(27)Retention of a complete dentition throughout lifetime should be the primary goal of the dental professional. Dental hygienists, including therapists and dental nutritionists, would help in the development of a sound oral hygiene and dietary changes, which in effect would reduce the

occurrence of dental caries and periodontal diseases. In addition, community water fluoridation is one among the most cost-effective methods for preventing tooth decay. Globally, studies denote reduction of dental caries about 40-50% in deciduous dentition and 50-65% in permanent teeth.(28) Despite the fluoride-related preventive efforts in primary schools as a national protocol since 1997 (29, 30),dental caries remains as the major problem in a proportion of the population. Regular dental checkups are still not a routine pattern of behaviour for allindividuals as evidenced by the levels of periodontitis observed which has been linked to various systemic diseases.

Conclusion

Dental extractions are a cause of anxiety for patients both in terms of pain management and the edentulous space created post-extraction.Possible complications also include alveolar osteitis, infection, haemorrhage, paresthesia and less common iatrogenic effects. Avoiding extractions therefore suggests that prevention of tooth loss is a herculean challenge due to the various causes. The results of this present study indicate that periodontitis is the major cause for tooth extraction in males with caries and periodontitis among female patients.Strategies for efficient methods to screen and impart dental education for both etiologies with prolonged periods of follow-up is the need of the hour and must be seriously considered to improve the quality of life for such patients.

Abstract

Introduction: Good behavioural management techniques are essential for treating children. The establishment of good rapport between dentist and patient makes the success of treatment, whether in terms of the child's co-operation in undergoing treatment or in following prevention and advice. Various methods were used in pediatric dentistry to manage the child.The aim of the study was to analyze and assess the behaviour of children during their dental visit and to determine the effect of behavior management techniques.

Materials and Methods: The study was conducted in the Department of Pedodontics, to assess the behaviour of children during their dental visits and to determine the effect of behavior management techniques on children. The study was done by analyzing the records of children between the age group of 3 years who had undergone dental treatment.

Results: In this study, there were about 45% of the studentsfeltcomfortable with the parental accompaniment for their pediatric patients under the age of 3, 54% of the students felt pressured by parental expectations and 85% of the students felt comfortable with the tell show do technique.

Conclusion: Among all behaviour management techniques, the undergraduate studentsfeltcomfortable with the Tell show do techniquein dental practice.

Key Words:*Child's behaviour, techniques, management, undergraduate students, attitude.*

Introduction

One of the most challenging problems faced by dental practitioners and dental students is behaviour management.(1,9)Psychological variables (anxiety and/or stress), socio-cultural (individual characteristics, children's maturity, previous dental experience) and legal requirements (parent's consent) are involved in dental treatmentinterfering with professional performance.Behaviour management techniques (BMTs) that facilitate the delivery of treatment in a safe, efficient and compassionate manner are an integral component in the practice of pediatric dentistry.(2,8,10) This helps in good rapport between the dentist and the child in order to achieve the goal of the dentist.(3,4,5)There are different behaviour management techniques that are used in dentistry for good cooperation of the child.They are Tell show do, nitrous oxide, papoose board, voice control, hand over the mouth, oral pre medication, active restraint, general anaesthesia, dentist spending time in waiting room prior to treatment, dental assistant spending time in waiting room prior to treatment, live modelling, video modelling.These techniques are helpful in the success of dental treatment.(6,7)

Materials and Methods

This is across-sectional questionnaire based study on commonly used behaviour management techniques among undergraduate students. Data were collected from 100 undergraduate students of Saveetha dental college, Chennai. The questionnaires were based on three categories that included parental accompaniment scale, parental expectation scale and proportion of dentists feeling with each behaviour management techniques.Therewere eight open questions under parental accompaniment scale, four questions under parental expectation scale and twelve questions under proportion of dentists feeling with each behaviour management techniques. The questionnaires were used to assess the knowledge of the dental practitionersbasedonthe behaviour of children during their dental visits and to determine the effect of behavior management techniques on children.(15)

Results

This study was performed among 100 undergraduate students of Saveetha dental college, Chennai. 68 females and 32 males answered the questionnaire.They were under the age group of 18-23 yrsstudying 3 rdyr, 4 thyr and Internship of Bachelor degree of dental

surgery.Therewere five options for each questionnaire.Theywere strongly agree, agree, neutral, disagree and strongly disagree.(21,22)

Table 1: Shows the parental accompaniment scale based on no of questions and no of undergraduate students who answered the questions.

No of questions	**Strongly agree (in %)**	**Agree (in %)**	**Neutral (in %)**	**Disagree (in %)**	**Strongly Disagree (in %)**
1.In General, children under the age of 3 behave better when one of their parent is present during the course of the treatment.	45%	15%	10%	5%	25%
2.In general, children over the age of 3 behave better when one of their parent is present during the course of treatment.	37%	14%	29%	20%	0
3.In general, separating children from their parents when dental treatment commences	25%	45%	30%	0	0

simply increases the child's anxiety.					
4.In most cases, parental accompaniment of the child assists the dentist because it increases the child's anxiety.	34%	26%	22%	12%	6%
5.In general, I support parent accompaniment of the child during the course of the treatment.	23%	57%	20%	0	0
6.I think parental accompaniment of the child during treatment is counter productive.	15%	34%	40%	5%	6%
7.In general, I feel comfortable managing a child when the parent is present during treatment.	28%	32%	20%	7%	13%
8.I prefer	12%	67%	12%	9%	0

parents to stay in the reception room whilst I am treating the child.					

Table 2: Shows the parental expectation scale based on no of questions and no of undergraduate students who answered the questions.

No of questions	**Strongly agree (in %)**	**Agree (in %)**	**Neutral (in %)**	**Disagree (in %)**	**Strongly disagree (in %)**
1.Many parents have unrealistically high expectations of their child's treatment.	20%	50%	10%	7%	13%
2.I often feel pressured by parental expectations of their child's treatment.	37%	48%	15%	0	0
3.I feel increasingly pressured by parental expectations.	54%	23%	12%	6%	5%

4.I sometimes feel that parents do not trust me in treating their child.	42%	28%	10%	13%	7%

Table 3: Shows proportion of dentists feeling 'totally comfortable or uncomfortable'with each behavioural management technique.

Behaviour management techniques	**Totally comfortable**	**Uncomfortable**
Tell show do	85%	15%
Nitrous oxide	20%	80%
Papoose board	35%	65%
Voice control	68%	32%
Hand over mouth	47%	53%
Oral pre- medication	12%	88%
Active restraint	32%	68%
General anaesthesia	45%	55%
Dentist spending time in waiting room prior to treatment	56%	44%
Dental assistant spending time in waiting room prior to treatment	68%	32%
Live modelling	82%	18%
Video modelling	75%	25%

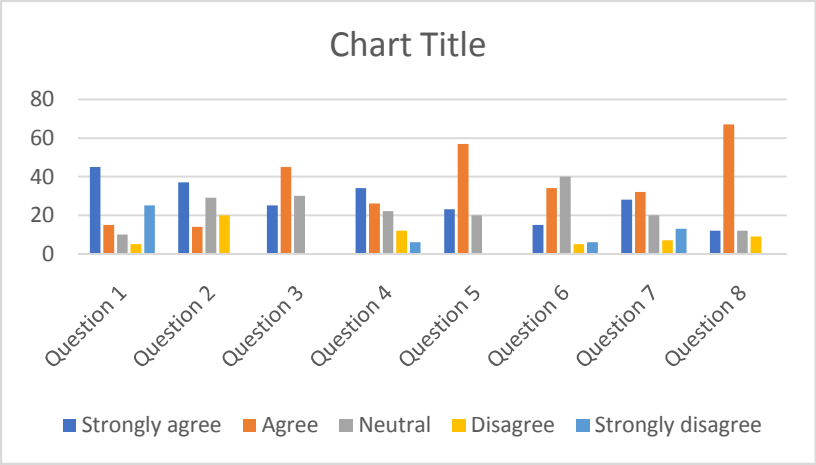
Discussion

The study was based on three categories. They were based on parental accompaniment scale, parental expectation scale and proportion of dentists feeling for each behaviour management techniques.The questionnaire contains eight direct questions.100 undergraduate students

answered these questions. Five similar options were given to all the questions. The option were strongly agree, agree, neutral, disagree and strongly disagree. The students answered the questionbased on their way of treating the child and the success of the treatment.

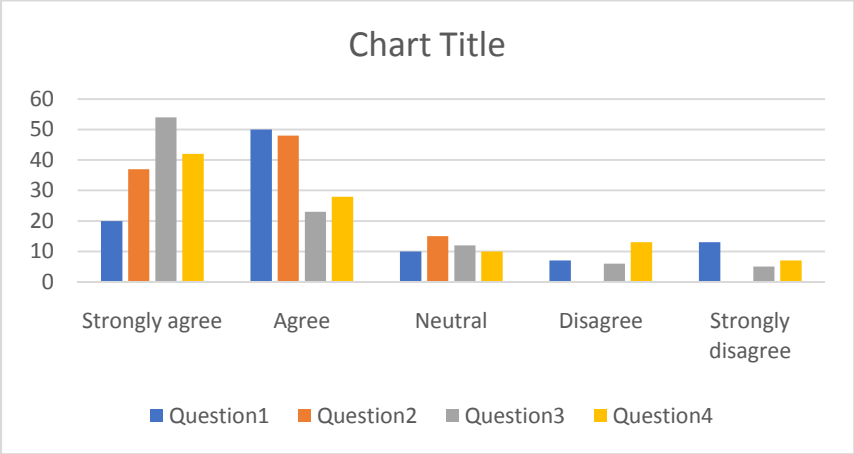
In majority of the cases, The parental accompaniment was strongly agreed only under the age of 3 to make the behaviour of the child better during the course of the treatment. It was strongly disagreed, asit may increase the child's anxiety during the treatment.(5)Generally, the behaviour of the child was different, if they were above the age of 3and it is difficult to manage the childwith the parent during the treatment. Based on the parental accompaniment the dentist feeling was recorded in chart 1,

Chart 1: Shows the parental accompaniment scale based on no of questions and no of undergraduate students who answered the questions.



The expectation level of the parents would be higher, due toincreased use of the internet for information and the trend of medical television shows may have increased the awareness of oral cavity.In majority of the cases, the parents does not trust their dentist and they felt pressured in most of the situations during the treatment.(5)In parental view, the basic trust on the dentist was more importantto overcome the treatment. The expectation level of the parent was recorded in chart 2,

Chart 2: Shows the parental expectation scale based on no of questions and no of undergraduate students who answered the questions.



In the last several decades, the acceptability of various behaviour management techniques have changed with pharmacological techniques like sedation and general anaesthesia getting better acceptance in recent studies.(7)

Examining the results, oral premedication and general anaesthesia were ranked the lowest acceptable techniques in 1984 and 1991.(21) However, acceptability for both pharmacologic methods increased in subsequent studies from 2005 till 2017.(22) Now it is quite interesting to speculate the reasons of this paradigm shift towards pharmacological methods. Changing attitudes toward acceptability of behavior management techniques may be attributed to changes in parenting styles over the past years. A recent study reported parents are more overprotective and less likely to set limits on children's behaviour. As a result, there may be a shift towards more pharmacologic behavior management techniques.(10)

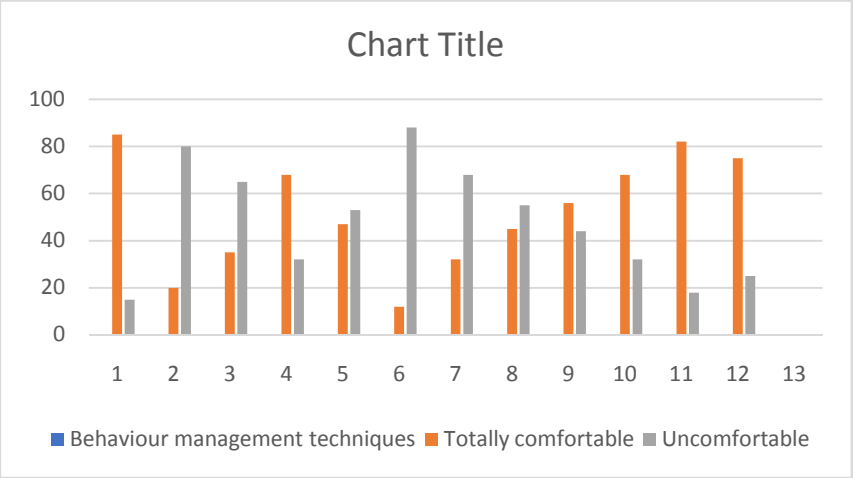
Changes in medications, with increased safety profiles and efficacy, used for oral premedication (sedation) over the years may also contribute to the rising acceptability. Overall, parents may perceive oral premedication (sedation) and general anesthesia to be less risky, more cost-effective, more comfortable for their children than in the past .(11,13)

Most parents in the present study preferred Tell – Show – Do followed by Live modelling to be employed on their children. These findings were consistent with a previous study, in which the most preferred techniques were Tell-Show-Do, Live modelling and Video modelling.(14) Findings were also consistent with previous study which found that most parents preferred an explanation as proper approach for treating their children.

Most of thedentistsin the present study moderately preferredHand over Mouth followed by physical restraint and voice control. These findings were consistent with another study which found physical restraint technique unacceptable by parents, however, the parents accepted GA in emergency dental situations.The acceptance of general anesthesia and sedation has

shown an increase in the present study when compared other studies. The most significant outcome of the study was the increased acceptance of pharmacologic behaviour management techniques.

Chart 3: Shows proportion of dentists feeling 'totally comfortable or uncomfortable'with each behavioural management technique.



Conclusion

This study, states that the parents wished to accommodate their child during treatment so that they feel comfortablewith the treatment, but the dental practitioner doesn't want parents to accompany their child in all situations.(20) In some situations parents were asked to leave the child because of some unwanted behaviour of the child .Behaviour assessment helps us to plan appointments and provide quality oral health care to children. Proper use of management techniques improves behaviour on subsequent visits, making things easy for the child and the pediatric dentist. Assessment and evaluation helps us to reinforce our beliefs in our own techniques.This study shows the commonly used behaviour management techniques. They were evaluated based on the parental accompaniment scale, based on parental expectation scale, based on proportion of dentists whether they were feeling comfortable or uncomfortable with each behaviour management techniques.It is a questionnaire based study among undergraduate students. The questionnaire contains direct questions with similar options. The evaluation of this is study based on the way of treating the child and the success of the treatment. The result of the study shows the dentists feelscomfortable with the parent accompaniment during the treatment, but not in all situationsand also the dentists feel increasingly pressured by theparentalexpectation. A wide variety of behaviour management

techniques are available in paediatric dentistry but Tell show do techniqueis the commonly used behaviour management techniquefor treating the children among undergraduate students. This is a method of introducing child patients to a procedure in a step wise manner. It has its own hierarchy tell, then, show then do to allow the child to assimilate the procedure in a graduated manner. Thus the proper use of the behaviour management techniques makes the child feel comfortable and minimise the anxiety during dental procedures.

Abstract

Introduction: Occlusal plane orientation is an important factor in the construction of a complete denture. Occlusal plane could be oriented using landmarks in the mandibular arch as well as in the maxillary arch. In the mandibular arch there are few landmarks which could be used to orient the occlusal plane like the retromolar pad, corner of the lips (lower lip length) whereas the maxillary arch has a number of landmarks, of which the ala-tragal line is the most commonly used. The present study was designed to assess the knowledge of dental students on landmarks used in occlusal plane orientation. The aim of this study is to assess the knowledge of the dental students about the widely used landmarks for occlusal plane orientation in construction of prosthetic dentures andwhether they implicate during the treatment of patients.

Materials and Method: A cross- sectional questionnaire survey was conducted among 100 students of saveetha dental college and hospital divided into two groups (inclusion criteria- final years[50] and interns[50]). Data were collected using a self- administered questionnaire adapted from several studies addressing various aspects of knowledge and attitude of students on landmarks used in occlusal plane orientation for the construction of denture both in static and dynamic relation.

Statistical Analysis: The data was first transferred into Microsoft spread sheets. All of these results were analysed by using SPSS statistical software in terms of percentages. (statistical package for social sciences, SPSS Inc., Chicago, IL, USA). Associations between

discreet variables were tested by chi square test. p value≤ 0.05 was considered to be statistically not significant.

Result: In present study, the results showed that there was lack of knowledge on the landmarks used in occlusal plane orientation among the students. Interns had a good knowledge on occlusal plane orientation and implicated it during the treatment of patients when compared to final years since interns got more of clinical exposure than the final years.

Conclusion: In conclusion many students had a good knowledge on landmarks used in complete denture construction but the same did not reflect in their attitude and practice. It is worthwhile to attempt more of teaching should be given on various landmarks used in occlusal plane orientation among the students so that they get to more about the landmarks and implicate in their clinical practice.

Key Words*: occlusal plane, camper line, landmark, esthetics, denture*

Introduction

Occlusion in prosthodontics is extremely important .Occlusal plane orientation is been playing an important role in construction of complete dentures. Complete denture prosthodontics is a challenge for the restoring dentist for the reason that rehabilitation of edentulous patients with conventional complete dentures, be it tissue supported or implant supported, has to be done by considering various biological and mechanical factors to restore function and health of the stomatognathic system [1]. Developing an occlusion that is compatible with functional movements of the stomatognathic system is one of the key factors in determining the prognosis of the completely edentulous patients [2]It is said that for the success of complete denture prosthesis the teeth must be arranged in the correct plane of occlusion. The orientation of occlusal plane forms the basis for teeth arrangement conducive to the satisfactory esthetics and proper function. Occlusal plane is said to be the " plane established by incisal and occlusal surface of the teeth. Occlusal plane orientation can be established by both maxillary and mandibular arch[3]. Occlusal plane helps in phonetics and aesthetics anteriorly whereas in posteriors it forms a milling surface. Any changes in the plane of occlusion will lead to the modification of physical and functional relationship of oral musculature leading to an alteration in function, comfort and aesthetic value. The correct

orientation of the occlusal plane plays a vital role in optimal esthetic achievement. In the natural smile, the incisal tip follow the curve of the lower lip[4]. This effect is an expression of a correctly oriented occlusal plane; if the occlusal plane hangs posteriorly, the lip-line viewed from the front will appear straight and contribute more than any other factor to the so-called 'denture look'. With the occlusal plane correctly oriented, however, the natural anterior curve will be achieved almost automatically and contribute a proper sense of perspective to the dental composition [4].The plane of occlusion, forms an essential part of the concept of mechanically balanced articulation [5]. The position of occlusal plane in denture wearers should be as close as possible to the plane, which was previously occupied by the natural teeth [6]. Such position of the occlusal plane provides normal function of the tongue and cheek muscle, thus enhancing the denture stability [7].

It is believed that teeth oriented on an occlusal plane in harmony with the individuals physiognomy is responsible, in part, all conditions being equal, for stable, retentive full dentures [8]. Faulty orientation of the occlusal plane will affect the interaction between tongue and buccinators muscles [9]. Where the occlusal plane is too high, the tongue cannot rest on the lingual cusps of the lower denture and prevent its displacement. Also it forces the tongue into a new position that is higher than its normal position [10]. This higher position of the tongue causes the floor of the mouth to raise and create undue pressure on the border of the lingual flange and results in partial loss of border seal [11]. There is also tendency for accumulation of food in the buccal and lingual sulci. An occlusal plane that is too low could lead to tongue and cheek biting [12] Hence our goal in treating the patients is to restore the occlusion with free of occlusal interference. In mandibular arch there are few landmarks which could used to orient the occlusal plane like retromolar pad,corner of the lips meanwhile the maxillary arch has a number of landmarks in which the ala tragus line is most commonly used. Considering the importance of the accurate establishment of the location and inclination of occlusal plane on function, esthetics and speech, a method to conform it to the occlusal plane that existed in the natural teeth seems necessary. The question which arises in clinical practice is how to discover which position was occupied by the "natural occlusal plane" after the loss of natural teeth and exactly, how can the optimal position of the occlusal plane be found in every edentulous patient [13].

The occlusal plane in anterior and posterior regions may vary and therefore, these should be evaluated separately. It is generally agreed that in the anterior region the vertical height of the

occlusal plane is governed by esthetic requirements [14] and less frequently by functional demands. The anterior maxillary occlusal plane may be determined by lip relationships at rest and when smiling. Speech also provides for positional accuracy [15]. When viewed from the front, the occlusal plane should be parallel to the interpupillary line [16].With regard to the orientation of the occlusal plane in the posterior region, however, there are contrasting views. Various authors have postulated various landmarks for determining the occlusal plane. The objective of this study is to evaluate the knowledge and attitude of dental students about the landmarks used in occlusal plane orientation and whether they implicate it in their daily practise.

Materials and Method

Study Design

A cross-sectional study was conducted among 100 students of saveetha dental college, divided into two groups (50 final years and 50 interns) Chennai,Tamilnadu. The study was conducted during the month of April 2015 after taking prior informed consent from the students who were willing to participate. Inclusion criteria were the students who have done atleast one prosthetic denture for the patients. In addition, students who where studying final year and internship were only included in the study. Final years and students who were doing internships were only included in the study since they seem to have more exposure on clinical practice when compared to third years as the third years have just entered into clinical practice. Henceforth first year, second year and third year have been excluded in the study.

Methodology

The self-administered questionnaire written in English was adapted from several studies The students were asked to fill in the questionnaire which had 2 set of questionnaires.It had 14 questions, 7questions in the knowledge of landmarks in mandibular arch and 7 questions on landmarks of maxillary arch,and took about 10–15 min to complete. The scoring for knowledge and attitude on landmarks of occlusal plane orientation included yes/NO. This

pretested questionnaire addressed the knowledge regarding the occlusal plane orientation both in static and dyamic relation.

Result

Mandible

Graph 1: Aware that retro molar pad is used in occlusal plane orientation?

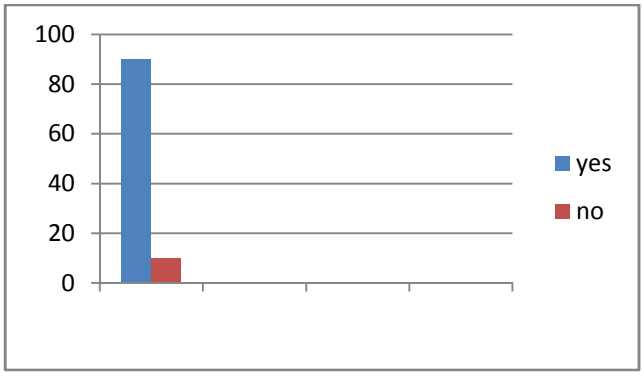

Table 1: depicts that , 91% of students were aware of use retro molar pad landmark in occlusal plane orientation whereas only 9% unware of it. The statistic result showed it is significant at p<.05

Year	Yes	No
Final year	41(45)[0.2]	9(5)[1.8]
Intern	48(45)[0.2]	2(5)[1.8]
Total	91	9

Chi square statistic is 4. P value is 0.0455, result is significant at p< .05

Graph 2: Do you implicate the use of retro molar pad in occlusal orientation in your dental practice?

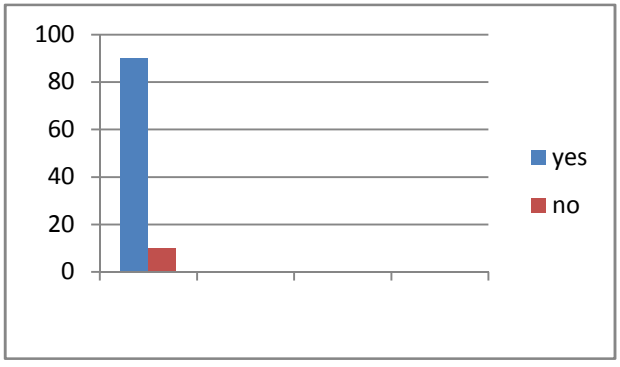

Table 2:Demonstrated, about 90% of students implicated the use of retro molar pad in the dental practice. Interns were more aware and used retro molar pad as landmark for occlusal plane orientation when compared to final years

Year	Yes	No
Final year	39(45)[0.2]	11(5)[1.8]
Intern	48(45)[0.2]	2(50)[1.8]
total	90	10

Chi square statistic is 4. P value is .0455, result is significant at p<.05

Graph 3:Do you think occlusal plane coincide with the middle third of retro molar pad?

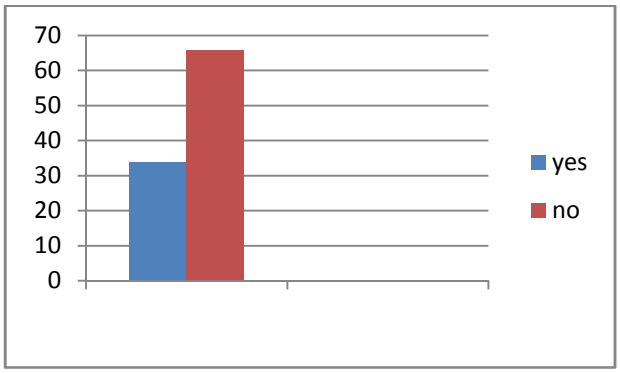

Table 3: Depicts, when asked about occlusal plane coincidence with the middle third of retro molar pad, 90% gave a positive affirmation on it.

Year	Yes	No
Final year	42(45) [0.2]	8 (5) [1.8]
Intern	48(450 [0.2]	2 (5) [1.8]
Total	90	10

Chi square test statistic is 4, p value is .0455. it is significant at <.050

Graph 4:Do you think the lateral border of the tongue reliable for occlusal plane orientation?

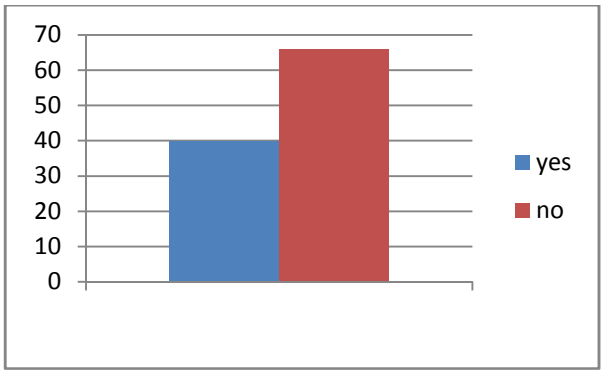

Table 4: Depicted, 66% of the students think lateral border of the tongue is not more reliable in occlusal plane orientation and 34% agreed lateral border of tongue should be used as significant landmark in occlusal plane orientation.

Year	Yes	No
Final year	21(17) [0.94]	29 (33) [0.48]
Intern	13(17) [0.94]	37(33) [0.48]
Total	34	66

Chi square test statistic is 2.852, p value is .091258, result is not significant at $p<.05$.

Graph 5: Do you use commissure of lips for the occlusal plane orientation?

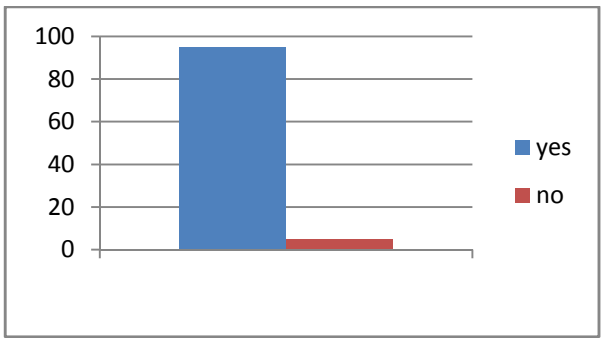

Table 5:Showed positive results towards the use of commissure of lips for occlusal plane orientation, students agreed that commissure of lip is seem to be the main landmark for orientation in mandible

Year	Yes	No
Final year	47 (47.5) [0.01]	3 (2.5) [0.1]
Intern	48 (47.5) [0.01]	2 (2.5) [0.1]
Total	95	5

Chi square test statistic 0.2105.p value is .646355. not significant at p<.05

Graph 6: Is the commisure of lips more reliable for occlusal plane orientation?

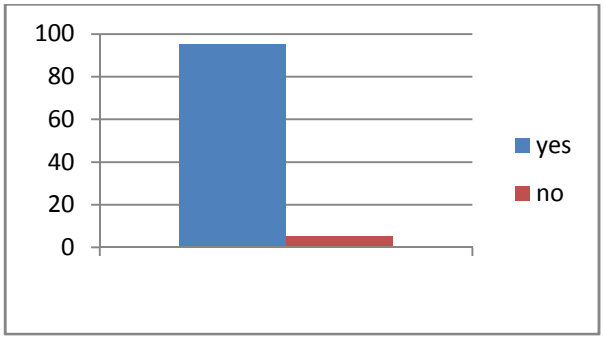

Table 6: Depicted, students agreed that commissure of lip is seem to be the main landmark for orientation in mandible and also most reliable.

Year	Yes	No
Final year	47(47.5) [0.01]	3(2.5) [0.1]
Intern	48(47.5) [0.01]	2(2.5) [0.1]
Total	95	5

Chi square test statistic 0.2105.p value is .646355. not significant at p<.05

Graph 7: Do you use buccinator groove as a landmark in occlusal plane orientation?

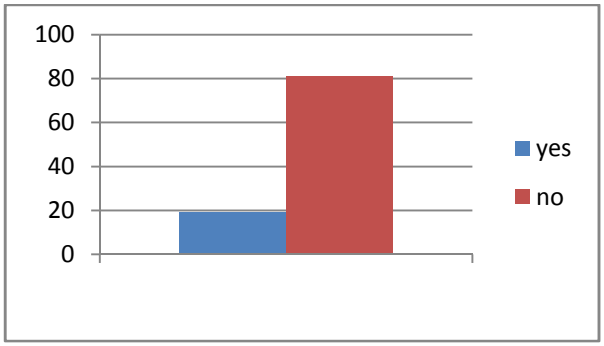

Table 7:Depicts, about 81% of students were unware of the buccinator groove being used as a landmark in occlusal plane orientation.

Year	Yes	No
Final year	8 (9.5) [0.24]	42(40.5) [0.06]
Intern	11(9.5) [0.24]	39(40.5) [0.06]
Total	19	81

Chi square test statistic 0.5848.p value is .4449, not significant at p<.05

Questionnaire 2

Maxilla

Graph 8: Are you aware that parotid papilla is used in orientation of occlusal plane?

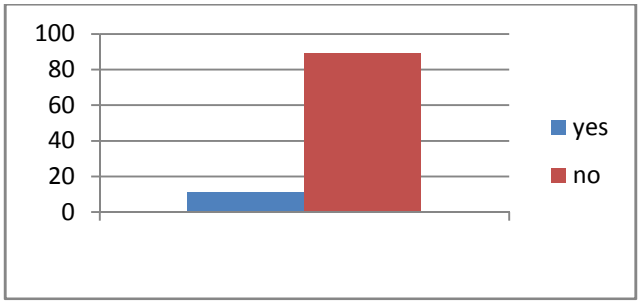

Table 8: Demonstrated, 89% of students believed that use of parotid papilla was not necessary in occlusal plane orientation.

Year	Yes	No
Final year	3(5.5) [1.14]	47 (44.5) [0.14]
Intern	8(5.5) [1.4]	42 (44.5) [0.14]
Total	11	89

Chi square test statistic 2.5538.p value is .1100, not significant at p<.05

Graph 9: Do u think hamular notch is reliable in occlusal plane orientation?

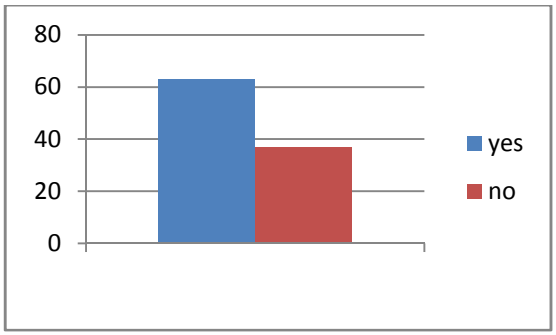

Table 9:Showed, 63% of participant thought hamular notch is reliable in occlusal plane orientation whereas 37% disagreed with it.

Year	Yes	No
Final year	27(31.5) [0.64]	23(18.5) [1.09]
Intern	36(31.5) [0.64]	14(18.5) [1.09]
Total	63	37

Chi square test statistic 3.4749, p value is .0623, not significant at p<.05

Graph 10: Is the parallelism of occlusal plane to ala Tragus line necessary

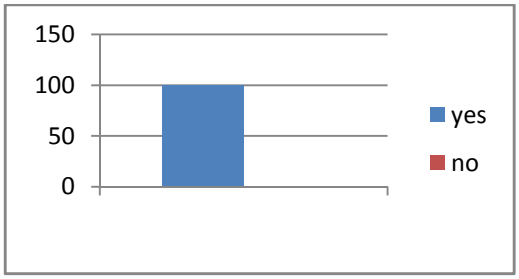

Table 10:Depicts, all the students believed that the ala tragus line is the must when doing complete denture procedure and it should be parallel to the occlusal plane of rim.

Year	Yes	No
Final year	50(50)[0]	0
Intern	50(50)[0]	0
Total	100	0

Chi square test statistic is 0, p value is 1, not significant at <.05

Graph 11: Do you think the occlusal plane orientation is necessary for aesthetics and functioning of denture?

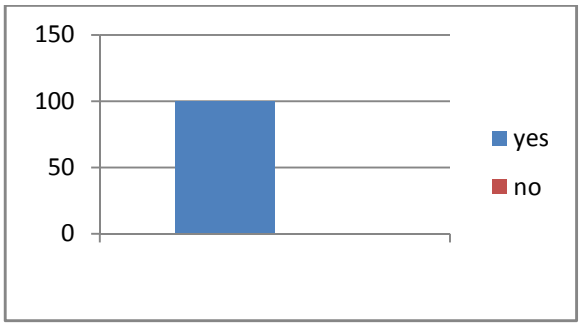

Table 11: Depicts, the main aim for doing occlusal plane orientation is for aesthetics and functioning of denture. All the participants accepted that occlusal plane orientation is a must for aesthetic and functional movement.

Year	Yes	No
Final year	50(50)[0]	0
Intern	50(50)[0]	0
Total	100	0

Chi square test statistic is 0, p value is 1, not significant at <.05

Graph 12: Are you aware that interpupillary line is used in occlusal plane orientation

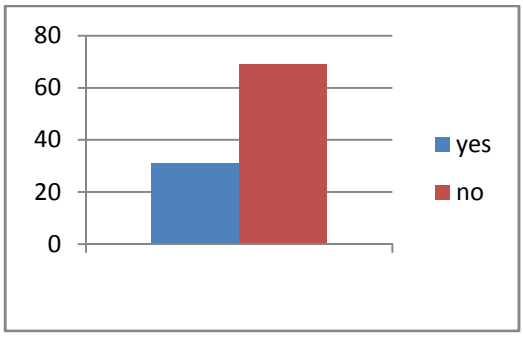

Table 12: Showed mixed response from the participates where few were aware of interpupillary line used in occlusal plane orientation whereas some participants were not aware of it.

Year	Yes	No
Final year	9(15.5) [2.73]	41(34.5) [1.22]
Intern	22(15.5) [2.73]	28 (34.5) [1.22]
Total	31	69

Chi square test statistic is 7.9009, p value is .004941, it is significant to <.05

Graph 13: Are you aware that visibility of maxillary rim should be 2 mm

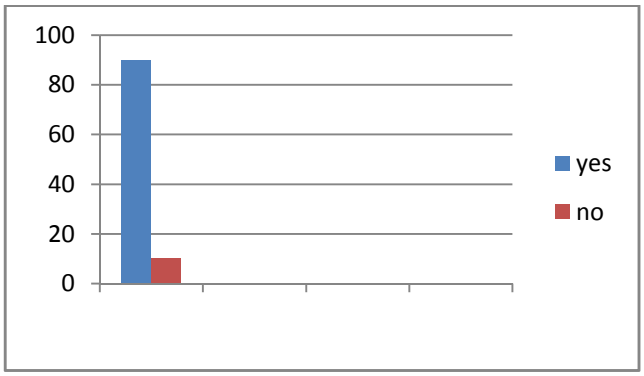

Table 13:Depicted except few, 90% of the participants were aware that maxillary rim should be 2 mm visible when the mouth is in the rest position and it is considered to be significant landmark in occlusal plane orientation

Year	Yes	No
Final year	42(45) [0.2]	8 (5) [1.8]
Intern	48(450 [0.2]	2 (5) [1.8]
Total	90	10

Chi square test statistic is 4, p value is .0455. it is significant at p <.50

Graph 14: Do you implicate in the clinical practise?

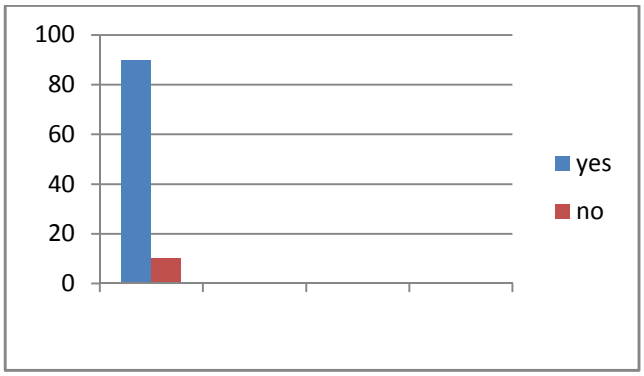

Table 14: Depicted**,** visibility of maxillary occlusal rim about 2mm at rest is must and most students have implicated it in their construction of complete denture.

Year	Yes	No
Final year	42(45) [0.2]	8 (5) [1.8]
Intern	48(450 [0.2]	2 (5) [1.8]
Total	90	10

Chi square test statistic is 4, p value is .0455. it is significant at p <.50

Discussion

The artificial replacement of lost teeth is generally desired for two prime reasons: esthetic and restoration of function. Prosthodontists are often confronted by edentulous patients complaining about ever increasing facial wrinkles and protruded chin with difficulties in function of mastication and speech. They have to limit the routine activities within the confines of anatomical, physiological and functional harmony, compensating for his losses and providing with optimum esthetic and function.[17] Such rehabilitation requires ideal positioning of teeth so that they appear natural and create a pleasing profile and yet, are conductive to function, phonetics and mastication. This in turn is possible only if the occlusal plane which forms an indispensable part of the prosthesis is correctly oriented vertically in the neutral zone[18].The Occlusal Plane orientation for the best esthetics and function has been of great concern to Prosthodontists because of its role in preservation and prevention of residual ridges. The stability of complete denture largely depends on the Occlusal Plane which is one of the most important factors that determines the success of removable prosthesis[19]. Considering the importance of the accurate establishment of its location and effect of its inclination on function, esthetics and speech, a method to guarantee its conformity with the Occlusal Plane of the missing teeth seems necessary. The orientation of Occlusal Plane has led to innumerable controversies.

Graph.2 demonstrated , about 90% of students implicated the use of retro molar pad in the dental practice and believed that occlusal plane coincided with the middle third of retro molar pad. Interns were more aware and used retro molar pad as landmark for occlusal plane orientation when compared to final years. In contrast to this a study done by Gupta et al used a metallic scale which passed along the cusp tip of cuspid to mandibular second or third molar and extended posteriorly to the retromolar pad. They concluded that in maximum

number of cases the occlusal plane coincided with the middle third of the retromolar pad. it is a soft tissue area and at times its anterior and posterior borders cannot be demarcated accurately[20]. Therefore relying only on this one landmark cannot guarantee complete validity to the occlusal plane orientation. However, when used as one of the guides for the occlusal plane orientation, the area in the lower third of the retromolar could be used.

Graph.4 depicted, 66% of the students think lateral border of the tongue is not more reliable in occlusal plane orientation and 34% agreed lateral border of tongue should be used as significant landmark in occlusal plane orientation. A study done by Ghosn et al suggested that since the tongue is a highly movable organ in the oral cavity and thus its reliability in the occlusal plane orientation is questionable. Also, after extraction of all teeth the tongue becomes hypertrophied, resulting in the change of the anatomy of the lateral border of the tongue[21].

Graph.6 depicted, students agreed that commissure of lip is seem to be the main landmark for orientation in mandible and also most reliable. A study done by Shigli et al suggested that Deciding on the commissure of lips as a guide for occlusal plane orientation is most unreliable, as with age there is drooping or turning down of the corners of the mouth. Therefore, commissures cannot be similar to as observed in dentulous patients[22].

A number of guides for its orientation have been implicated. These are Anthropometric, anatomic, biometric landmarks like Camper's plane and retromolar pad. Most of the Prosthodontist encountered difficulty in scheming an Occlusal Plane which is mechanically as well as esthetically acceptable.Ala-Tragus Line is one of the most popular methods is to orient the occlusal plane parallel to a line drawn from the lowest point of the ala of the nose to the external auditory meatus or tragus. Definitions of the ala-tragus line by different authors are a cause of confusion due to disagreement on the exact point of reference, on the ala and the tragus, for this line. Clapp in 1910 was the first to relate Camper’s line/plane to occlusal plane The Camper's Occlusal Plane was the first effort in modern dentistry to establish occlusal plane. It was based on scientific research and was made parallel to ala-tragus plane posteriorly. [23]

Kumar et al. found ala-tragus line is the most controversial landmark in occlusal plane orientation. However, this extra-oral landmark is reliable as both its ends do not change with age. Majority of the studies show that the line joining the inferior portion of the tragus with

the ala of the nose is more often than not parallel to the occlusal plane. Nonetheless, the superior and middle part of the tragus cannot be completely overruled as the lines formed with these landmarks and the ala of the nose have also proved to show parallelism with the occlusal plane. Therefore, a combination of more than one landmark should be used along with the ala-tragus line for orienting the occlusal plane[24].Although clinical judgment and experience are invaluable, method of making a systemic analysis of the Occlusal Plane to the craniofacial structures using cephalometrics would be a definitive aid. This would be especially true for completely edentulous patients since many of the existing landmarks have been lost. So as the location of Occlusal plane in complete denture fabrication is very subjective and it is widely variable depending upon the uncertainty of reference landmarks and the individual judgment. Therefore, the reliability of various reference planes as a clinical guideline for establishment of Occlusal plane needs to be tested.

Limitation of the Study

The design of the study was cross sectional in nature. The students participated in this study were final years and interns so the application of the results of this study to the general dental practitioner and post graduate could not be appropriate. The small sample size is also a limitation of the study.

Conclusion

This study throws a light that students must know various landmarks are available for the orientation of occlusal plane in edentulous patients. More emphasis must be given in teaching various landmarks used in occlusal plane orientation among the students.However, based on the various studies done on dentulous patients, no single method seems entirely accurate to locate the occlusal plane. Therefore, using one method alone will not suffice the determination of occlusal plane in edentulous patients. A combination of various landmarks along with a judicious clinical judgment should be taken into account for the location of the occlusal plane in edentulous patients**.**

Abstract

Introduction: Alveolar osteitis is a post-operative complication that interferes the healing process after tooth extraction. This occurs when a blood clot dissolves and alveolar bone exposure happens. These complications are usually associated with the impacted 3rd teeth. Since it is a most common complication that occurs after extraction, it is very essential for the dental students and dental practitioners to know the importance of dry socket**.**The aim of this study was to evaluate knowledge and awareness on prevention and management of dry socket among dental students and general dental practitioner.

Materials and Method:A cross- sectional questionnaire survey was conducted among 100 dental students (inclusion criteria- undergraduates -final years and interns) and 100 general dental practitioners in chennai. A short pretested questionnaire of 15 questions was given to them .The questionnaires were prepared and data collected using a self- administered questionnaire addressing various aspects of knowledge on prevention and management of dry socket among dental students and dental practitioners.

Result: This study revealed that knowledge about the prevention and management of dry socket among most of the general dental practitioners was adequate when compared to undergraduate dental students.

Conclusion: More emphasis must be given on the prevention and management of complications in exodontia such as dry socket.

Key Words*: dry socket, eugenol, chlorhexidine, mandible, curretag*

Introduction

The most common procedures which is been carried out in dental clinics and the most frequently done task at oral and maxillofacial surgery clinics is the extraction of teeth. This procedure is frequently followed by complications in the mandible incase of wisdom teeth[1]. Extraction of wisdom teeth is most commonly followed by complications in the mandible, which includes both iatrogenic(caused by the clinician) (e.g., nerve injury, bone fractures, etc.) and inflammatory ones, such as dry socket, postoperative pain, delayed wound healing, postoperative infection, hematoma, swelling and trismus etc[2]. Although the overall complication rate might be generally low, and most complications are minor, this surgery is so frequent that the population's morbidity of complications may be noticeable; thus, identifying methods to control or reduce them is a major concern. Besides, not all complications are rare. There are frequent and debilitating complications as well, including postoperative pain[3].

Pain is also one of the most common postoperative complications of extraction and might be caused by the release of pain mediators from the injured tissues. Pain is an important factor in clinical practice and could even discourage patients from seeking dental treatment. It begins after the anesthesia subsides and reaches its peak levels during the first postoperative day. If dry socket or infection occur, the onset of inflammation will complicate alleviation of postoperative pain[4].

Dry socket is known to be the most common complication of exodontia . It is also referred as alveolar osteitis ,postoperativealveolitis, alveolalgia, alveolitissicca dolorosa, septic socket, necrotic socket,andfibrinolyticalveolitis.This occurs when a blood clot dissolves andthe exposure of alveolar bone happens. Dry socket has following symptoms such as severe and progressive pain, halitosis, regional lymphadenitis which usually occurs 3 to 5 days after extraction.[5]

The incidence of dry socket is most common in mandible when compared to maxilla. Dry socket occurs mostly due to dislodgement of clot, bacterial infection, trauma, smoking, curretage of alveolus.[6] It shows increased fibrinolytic activity and activation of plasminogen to plasmin in the presence ofactivators in dry sockets. This fibrinolytic activity is affects the integrity of the post extraction blood clot.[7]However, prevention is very effective in dry socket. Identification of risk factors and their elimination using antibiotic prophylaxis had resulted indecrease in the incidence of dry socket.[8]

The occurrence of dry socket in an day to day oral surgery either dental practice is unavoidable. The most common risk factors of dry socket are smoking, surgical trauma, extraction of wisdom teeth,single extractions, age, sex, medical history, systemic disorder, extraction site, amount of anaesthesia, operator experience, antibiotics which we use prior to surgery, rate of difficulty of the surgery and the previous surgical site infection in addition to oral Contraceptives, menstrual cycle and immediate irrigation of post extraction site with normal saline.[9] The proper options of treatment are directed toward palliative care, such as the irrigation of the surgical site, avoiding curetting the extraction socket[10]. Packing with a zinc oxide– eugenol paste on iodoform gauze on the extraction site can be considered to relieve acute pain episodes, there is also new agents in the market which helps to accelerate the healing of the socket such as PRGF and GECB[11].

The prevention methods for dry socket include avoiding smoking before and after tooth extraction and a traumatic surgery, the use of antibiotics, such as, azithromycin, can be considered, the other preventive measures such as chlorhecidine rinse or gel and zinc oxide eugenol pack with iodoform gauze can be effective in the reduction of dry socket incidence[12].

The aim of our study is to assess the knowledge regarding prevention and management of dry socket among undergraduate dental students and general dental practitioners in chennai.

Materials and Method

Study Design

A cross-sectional study was conducted in Saveetha dental college Chennai,Tamilnadu among final years, interns and general dental practitioner in Chennai. The study was conducted during the month of April 2016 to October 2017 after taking prior informed consent from the students and practitioners who were willing to participate. Inclusion criteria were the students studying final year and doing internship in Saveetha dental college and dental practitioners who work in private sector in Chennai.

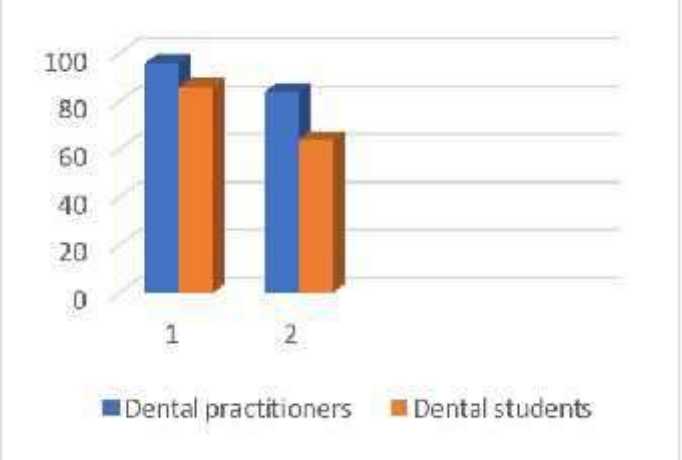
Methodology

This study was conducted to assess the knowledge of prevention and management of dry socket among the undergraduate dental students who were attending the Final year,

internship and general dental practitioners in chennai. 100 dental students and 100 dental practitioners were randomly enrolled in the study, who were present at the day of study. A validated short re-tested questionnaire of 14 questions was distributed among all the students and dental practitioners of the study. The questionnaire was designed at the aim of collecting the data about the prevention and management ofdry socket. Data extracted were statistically analyzed and results obtained.

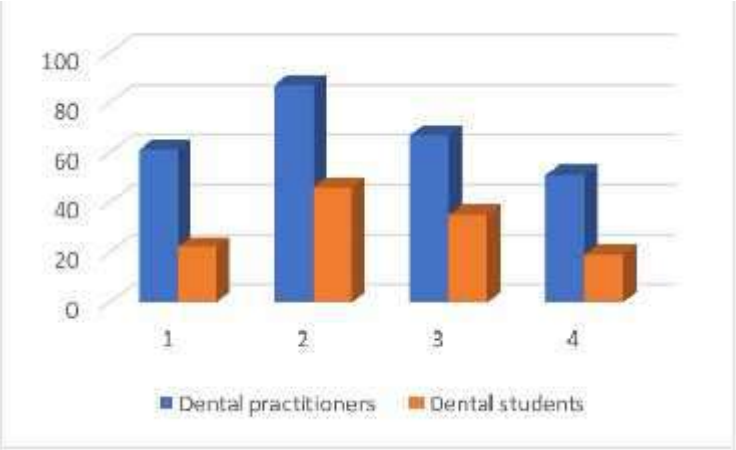
Result

Graph 1: Awareness about dry socket among dental students and dental practitioners



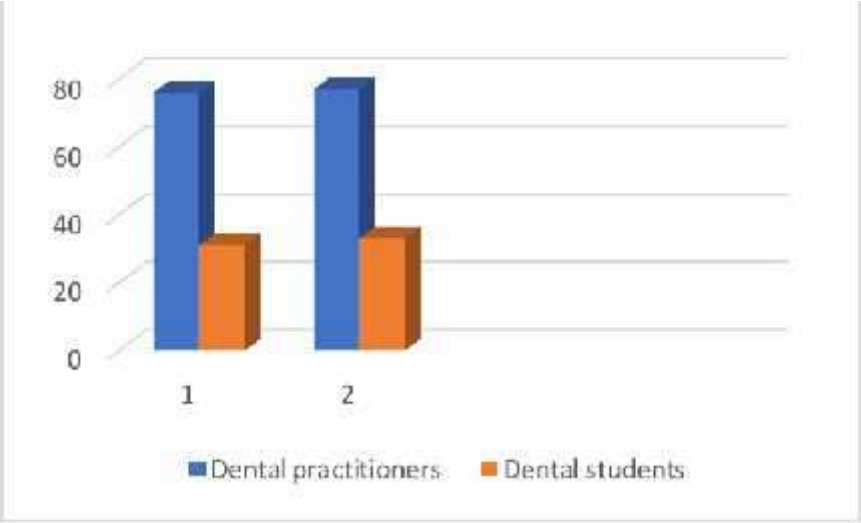
In this study, 90% of general dental practitioners knew that dry socket is a post operative complication of extraction and about 80% of the practitioners were aware that main cause of dry socket is due to dislodgement of clot (graph .1).

Graph 2: Awareness among dental students and practitioners towards management of dry socket



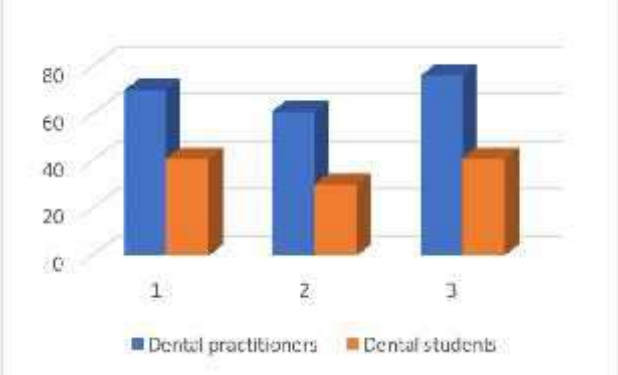
This study revealed that ,57% of dental practitioners used tranexa and chlorexhidine for the management of dry socket whereas only 33% of dental students had adequate knowledge on management of dry socket using tranexa and chlorexhidine. According to the survey 82% of practitioners believed that use of sutures and local haemostatic doesn't not help in management of dry socket. 62% dental practitioners had knowledge on effective management of dry socket using alvogyl when compared to dental students.(graph.2)

Graph3: Awareness towards advancement in management of dry socket



Anti-microbial photodynamic therapy and the low level laser therapy are known to be advancement in management of dry socket. Only 30% of dental practitioners were aware of advancement in management of dry socket and about 70% of dental students had inadequate knowledge on advancement therapy.(graph.3)

Graph 4:Awareness towards prevention of dry socket



70% of practitioners were aware that TTC and 0.2% of chlorexidinewas used for the prevention of dry socket. 85% of dental practitioners believed that induction of fresh bleeding is a proven modality for prevention of dry socket. Dental students had lack of knowledge on prevention of dry socket when compared to dental students.(graph.4)

This study revealed that knowledge about the prevention and management of dry socket among most of the general dental practitioners was adequate when compared to undergraduate dental students. This concludes more emphasis must be given on the prevention and management of complications in exodontia such as dry socket.

Discussion

Difficulties and complication of extraction are unpredictable. Taking medical history prior to surgery will make the dentist to deal better with the complications[14]. Dentist must be certain always to follow proper surgical techniques and should know limitations before beginning any extraction [15].The most common complication of extraction is alveolar ostetitis. According birnstudy ,there is increased fibrinolytic activity in dry sockets and the activation of plasminogen to plasmin with the presence of tissue activatorsreveals that increase in fibrinolysis decreased the chance of dissolution of the blood clot before the 2nd day after surgery ,because the blood clot contains antiplasmin , which is to be neutralized before clot dissolution occur. His study revealed that main cause of alveolar ostitis is due to dislodgement of blood clot[16].

According to our survey it revealed 80% of the practitioners were aware that main cause of dry socket is due to dislodgement of clot and awareness among dental students were inadequate when compared to dental practitioners.Chlorhexidine is a bisguanide antiseptic which is used as a preoperative irrigant and mouthwash tend to reduce the quantity of oral microbiota. Field et al(1987)[17] proposed that there was a decreased incidence of dry socket after irrigation of the gingival crevice with 0.2% CHX digluconate when compared with no irrigation or irrigation with saline. It revealed that incidence of dry socket was less when it was irrigated with chlorexidine. Our study proposed that ,57% of dental practitioners used tranexa and chlorexhidine for the management of dry socket whereas about 80% of dental students had inadequate knowledge on management of dry socket using tranexa and chlorexhidine.

Alvogyl is a medicated dressing which has the combination of (eugenol, iodoform and butamen), is used has a topical anesthetic and antibacterial for the management of dry

socket.62% dental practitioners had knowledge on effective management of dry socket using alvogyl when compared to dental students.

According to kaya G. et al[18], study, management of dry socket was significantlybetter in patients who are treated by curettage and irrigation followed by continuous- mode diode laser irradiation . Low level laser therapy also increased the speed of wound healing and reduced inflammation when compared to Alvogyl .It was used after the irrigation of socket as a continuous mode diode irradiation.

According to our study group, 70% of dental students were unaware of low level laser therapy and only 30% dental practitioners had knowledge on advancement therapy. This concludes more emphasization must be given on complication of exodontia such as dry socket.

Ortoluzzi MC et al[19]. observed the incidence of dry socket and they reported that there were higher pain levels and pain persisting longer than two days were observed with more traumatic surgeries, or associated with postoperative complications. Smoking was found to be statistically associated with the development of postoperative complications.

Mohammed H Abu Younis and Ra'ed O Abu Hantash[20] stated that the occurrence of dry socket are considered to be because of smoking, surgical trauma and single extractions are and factors like: age, sex, medical history, extraction site, amount of anesthesia, and operator experience have no effect on the observation of dry socket. The overall frequency of dry socket was 3.2%. Non-surgical extractions showed about 1.7% in incidence of dry socket while it was 15% following surgical extractions. The smokers showed high incidence of dry socket (12%) than in non-smokers (4%). However, this study showed a strong association between the amount of smoking and the dry socket incidence. Single extraction cases showed higher incidence of dry socket(15%),wisdom teeth than in the multiple extraction cases (6%). Age, sex, medical history, extraction site, amount of local anesthesia used in extraction and operators has no role in the occurrence of dry socket.

Eshghpour M et al.,andHasanMomeni[21], did two studies to identify the risk factor & the risk group of dry socket. Eshghpour M, et al[21],reported that the incidence of dry socket was about was 19.14%. Antibiotics, systemic disorder,age,gender which is been used prior to

surgery has no associations with alveolar osteitis significantly but the dry Socket incidence was significantly associated to smoking, difficulty index of the surgery according to pre-surgery radiograph evaluation and surgeons perception on post-surgery, length of surgery, and number of carpules which has been used to reach anesthesia, HasanMomeni, et al,stated that the incidence of dry socket was found to be more common in female than male which shows more predilection among females towards dry socket. 2.5 to 1 was ratio between mandible to maxilla and most common teeth involved is mandibular third molars than other teeth. Trauma, poor oral hygiene and smoking facilitate to increase the incidence of dry socket.Haraji et al[22], reported that the Alveolar Osteitis is decreased by the modified triangular flap more than the buccal envelope flap. In this study the patients where examined who were candidates for extraction of a bilaterally impacted mandibular third molar with the same difficulty index. In these patients a modified triangular flap was placed on one side and a buccal envelope flap (control) was placed on the other side,wound healing and dry socket were assessed at three and seven days after surgery.

Halabí D et al.[23], stated an increased risk of alveolar osteitis is most commonly associated with that the previous surgical site infection, traumatic extraction, and tobacco smoking

Al-Sukhun J et al[24].compared the use of the selective cyclooxygenase-2 (COX-2) inhibitor celecoxib among the patients, pre-emptively, and the patients who use the ibuprofen.The reported that the ibuprufen group had incidence of dry socket higher than the celecoxib group and the placebo group.

Rodrigues MT et al[25]. studied the effect of experimentally induced infection (the inoculation material contain *Capnocytophaga ochracea, Fusobacterium nucleatum, Prevotellamelaninogenica, Streptococcus anginosus, Treponemasocranskii* and *Streptococcus sanguis*) in the rat sockets, they reported that, it produced higher levels of serum C- reactive protein and showing the potential of disseminated infection and disturb in the alveolar repair process in an interesting experimental model for alveolitis studies. Krakowiak PA reported that; in certain patients, the normal process of healing can be delayed in some cases, because the sites was previously affected by osteomyelitis.

Another similar study emphasised that at the end of extraction on the development of dry socket that is alveolar osteitis after removal of impacted mandibular third molars use of

socket irrigation with a normal saline solution which is been routinely used showed significant differene in dry socket incidence [26](77.8% on the irrigated versus 22.2% on non-irrigated side) which revealed between the extraction protocol versus modified approach without any end-of-surgery irrigation. The study indicated that the post extraction socket bleeding is very important for the proper uncomplicated socket healing. If it's not washed away with irrigation solution at the end of extraction, the normal blood clot has a higher likelihood to form, and therefore, can potentially lead to an uncomplicated socket healing without development of alveolar osteitis.

Treatment option:Vessal G et al., and BezerraTP[27],studied that the dry socket were managed by antibiotics, and they reported that the amoxicillin was the most commonly used antibiotic. This study also reported that the multiple suture groups showed longer operation time, there was less pain, swelling and trismus significantly in the suture-less group, and significant difference between the two treatment groups in terms of pain, swelling and trismus was lesser. They also showed that the local hemostatic, primary closure, sutures and tranexamic acid showed lesser risk of postoperative bleeding after tooth removal in patients on continued warfarin medication.

In other study Kaya G. et al[18], compare effects of alvogyl, the SaliCept patch, and low-level laser therapy in the management of dry socket and the result showed no significant differences in the management of alveolar osteitis among the patients that treated by curettage and irrigation followed by alvogyl applied directly to the socket and the patients that treated by curettage and irrigation followed by a SaliCept patch applied directly to the socket. Patients treated by curettage and irrigation followed by continuous-mode diode laser irradiation showed better management of dry socket more than the patients who treated by curettage and irrigation alone- curettage and irrigation followed by alvogyl applied directly to the socket- curettage and irrigation followed by a SaliCept patch applied directly to the socket.

Burgoyne CC et al[28], assessed use of eugenol on a gauze strip versus a thermosetting gel containing 2.5% prilocaine and 2.5% lidocaine towards the efficacy of pain control for post extraction alveolar osteitis and he reported that the efficacy of the two preparations was not significantly different.

Conclusion

This study revealed that knowledge about dry socket prevention and management among most of the undergraduate dental students was inadequate when compared to general dental practitioners. Patients can attain good quality of treatment if our future dentist have more knowledge on post extraction complications and the methods of preventing and managing the complication.

Evaluation of Internship Programme of Undergraduate Students in A Private Dental College

Sahana Kritivasan[1], Pradeep Kumar[2], Shabeenataj[3]

Graduate Student[1], Reader[2], Department of Public Health Dentistry, Tutor[3], Department of Public Health Dentistry

Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract

Introduction: Dental education is at a critical state due to advances in health care delivery system. In dentistry one can gain extensive amount of knowledge only when they are students.The aim of this study is to assess the Internship programme of undergraduate students of a private dental college in Chennai.

MaterialsandMethod: A cross-sectional study was conducted among undergraduates. A pretested questionnaire was used to assess the internship experience like critical thinking knowledge,problem solving skills .senseof responsibility,creativity,professionalattitude, appearances, quality of work and ethics. Descriptive were analysed.

Results: It shows that about 72.3% of interns were satisfied about their internship achievements.

Conclusions: The study concludes that the internship programme have built in the clinical competency of the interns.

Key Words*: internship, self evaluation, learning, communication, curriculum*

Introduction

Dental curriculum changes dynamically hence it needs to be monitored and reconstructed according to the needs of the student, community and profession, otherwise it becomes stagnant.According to Shetty V.B, a good curriculum should always restructures itself and should receive feedback from all stakeholders. [1] The dental education is at a critical stake due to the advances and changes in the health care delivery system. There is a wide belief that the dental students are not satisfied with their experience in the dental colleges which may be due to the stressful environment. [2]Psychological stress or distress has long been regarded as an important influence on the learning and performance of the students. It serves as a motivation to some portion of the student community and for the rest it has adverse negative effect on their studies, health and personal lives. [3]

Being a consumer of the dental programme, the students view must be considered by the curriculum evaluation committee while updating the dental curriculum [4]. A self assessment can be conceived as an ingrained habit or trait to reflect an individual. Students of dental profession are bright; goal oriented and is reflective, sightful and consistent in academic and in assessing their skills and ability. [5].Hence the study was designed to analyse the perception of the interns about the present scenario of dental education, clinicaltrials, teacher-student relationship, professional outlook and patient care.

Materials and Method

A pre-tested structured questionnaire were given to 65 students of Saveetha Dental College and Hospitals, Chennai who were undergoing the internship programme. The feedback of the interns regarding the questionnaire were gathered and the data collected were entered for further evaluation. Evaluation of the data was done and the output was obtained.

Result

The results showed an overall satisfaction in achieving the internship roles and responsibilities along with performance(table 1), organisation and working environment(table 2) and finally the academic portfolio and extra curricularsactivites(table3).

Table 1: Internship Roles and Responsibilities with Performance

Items	Strongly disagree %	Somewhat disagree %	Neither agree nor disagree %	Somewhat agree %	Strongly agree %
Achievement of internship objectives	4.6	6.2	16.9	53.8	18.5
Demonstration of communication skill	3.1	13.8	6.2	49.2	27.7
Application of classroom knowledge	4.6	7.7	20.0	40.0	27.7

Discussion

It is very important to consider the perspective of graduating dental students regarding their curriculu, motivation and support. Also it is necessary o assess their internship experience like critical thinking knowledge,problem solving skills.sense of responsibility,creativity,professional attitude, appearances, quality of work and ethics.

The study show the various perceptions of the interns of a private dental institution should that there was overall satisfaction in acheievong the internship roles and responsibilities along with

performance. It also gives us an insight of the strengths and weakness of the current curriculum of that dental college which is monitored regularly.

Table 1 shows that about 49.2% of studnts have necessary communicaton skills. This is in accordance with the study conducted by Lanning S.K et al who quoted that, communication skills learned in the clinical setting, helps in providing a formal approach towards the patient and it is more efficient in enhancing the students confidence[3]. Also 49.2%of the interns have the ability of critical thinking and problem solving skills. About 50.8% of interns exhibit responsibility and defendabilty. About 49.2% were comfortable in handling all the assigned responsilities.

More than 40 percent of the students expressed that, they were able to apply their theoretical knowledge in their clinical practice which is higher than a similar study conducted by Ashri N in King Saud University,Riyadh.[4].

The internship tasks and responsibilities were handled comfortably by about 52.3 percent of the students which reflects that the students have gained adequate confidence to meet their goals and to understand their strength and weaknesses.

A study conducted by Kumar S in Rajasthan highlighted that students had stress due to the fear of their clinical in charge and the environment provided by the faculty to them during their clinical training [8].

The study by Chaudhary S mentioned that the way the practitioner carries himself influences the patients image of him or her[9]. Nearly 53.8 percent of the interns believed in maintaining a good professional appearance.

Nearly 40 percent of the students were elated about being a self sufficient worker as an individual as well as a team worker. A study in UK by Evans J showed the need for the development of a positive attitude towards inter professional education which will help in

maintaining a good team work with the technicians and their colleagues which will lead to a better collaborative practice.[10]

This was furtherillustrated in a study done by Leisnert L in Sweden where the students responded that patient needs to be approached holistically which should be a permanent part of education.[11] About 47.7 percent of the students appeased positive attitude towards their co workers. This helps them to respect each other's role in providing care for the patient.

The Association of American Medical colleges considers ethical responsibility to self and others, reliability, adaptability and dependability as the crucial for effective professional behaviour.[12] Being an intern student who is going to be exposed to private practice soon needs to be aware and exhibit the same. About 50.8 percent of the students exhibited responsibility and dependability during the course work.

Nearly 50 percent of the students exhibited professional attitude to behave ethically and 40 percent of the students were sensitive to diversity at the working environment. Diversity during the clinical practice includes the difference in gender, socioeconomic status, religion of the co workers and patients.

About 47.7 percent of the students were able to adapt to the changing circumstances and 46.2 percent of the interns believed that the working environment was stimulating for them to perform from better to best.

Table 2 shows that about 56.9% agree that the working environment provides sufficient orientation to its mission , purpose , culture ,polices and practices . About 50.8% of the interns were stiulated by regular assistance and willingness of the faculty to clear their queries regarding specific tasks. Attitude of the faculty towards the intern helped in modulating their perspective of achieving their objectives.

Nearly 43.1 percent of the interns were satisfied in providing feedback and discussing organisational matters. Asimilar study was done by Curtis D.A in University of California which the organisation invited its students to a provide a self assessment feedback of preclinical examinations.[13]

The number of clinical procedures done by the interns provided them with adequate training and professional skills. This was strongly agreed by 66.1 percent of the students while in a similar approach done in Riyadh reported only 59.8 percent of its students were satisfied with the quantity and quality of work produced by them in different branches of dentistry that helped them in becoming a self sufficient clinician at the undergraduate level.[4]

Adding on to the work production, selection of proper techniques and giving proper care provides a good orientation to their mission as a clinician. This was also sighted in a study by Marchan S.[6]

A major portion of the study population agreed that the work was challenging and will help them in improving their performance and observational skills during their clinical practice.

Table 3 shows that about 41.4% of the iterns were highl elated with the usage of facilites like like CAD-CAM, RVG, TOUCH ON CLOUD, DENTAL COLLEGE RECORD MANAGEMENT SYSTEM USING IPAD.[15,16,17,18,19]Also it has newer methods of learning and opens out vast areas of resources. These revolutionary technologies enhance the dental practise and education.[18'19]The ciruculam also provides oppurtunites to add credentials to their profile by participating in conferences and seminars. This enourages the to tackle different obstacles that arise while engaged in research work.

A library is an important aspect of every institution but the usage and the importance of it is lacking in almost all the students.Only 40 percentage of the students realised the benefits of the adequate resources found in the library for various academic and research oriented purposes

where as in a parallel study done by Shetty V highlighted its grief of only 35 percent of its students were satisfied with the library resources.[1]

Apart from the academic mission and orientation, the institution also provides an equal opportunity for its students to showcase their talents. By providing a platform for these talents to its students the institution will be able to explore ways to reduce stress among them and increase the efficiency of work produced by them.

Conclusion

This study has investigated the internship program of a private dental college in Chennai. Feedack of the interns highlights the success of the ciriculum. The enormous work produced by the interns helps to adapt to changing environment and overcome the stress. Patients satisfaction, time management and potent assessment becomes fruitful with efficient communication skills. The strength of the current program were a provision to critical thinking , problem solving skills , exhibiting responsibility , providing good working environment and revolutionary computer technologies.

Evaluation of Knowledge, Experience and Perception about Medical Emergencies among Dental Graduates (Interns)

M.Indhumathi[1], Shantha Rajan[2], Hemavathy.O.R[3],
Graduate Student[1],Senior Lecturer[2], Department of Pedodontics,Reader[3], Department of Oral and Maxillofacial Surgery,
*Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, I*ndia

Abstract

Introduction: The study is based on effective management of an emergency situation in the dental office . The lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legal action. For this reason, all health professionals including dentists must be well prepared to attend to medical emergencies. Providing basic life support [BLS] is dentist's most important contribution until definitive treatment for a medical emergency can be given. The aim of the study is to evaluate the knowledge, experience and perception about medical emergencies amongst dental graduates (interns)

Materials and Methods: Data were collected from 100 Interns of Saveetha dental college of chennai, India by using a structured questionnaire consisting of 7 item questionnaire (6 closed and 1 open).
Statistical analysis was performed to analyse the study.

Result: Among 100 dental students, who participated in the following study, only 70% of them were aware of the medical emergency drugs and their uses , the confidence level of the students were abruptly good in those students and 30% of the students should improve the level of confidence in using and handling of the drugs.

Conclusion: The study is useful to gain knowledge for the dental students in case of medical emergency situations.

Key Words*: Medical emergencies, dental graduates, basic life support.*

Introduction

Medical emergencies can be alarming to any clinician but these situations are less alarming if proper preparations are made. Medical emergencies occur in dental practice more frequently .Fortunately, serious medical emergencies in dental practice are not common but they are all the more alarming when they occur . A thorough patient history can draw the practitioner's attention to potential medical emergencies that could occur.(1) Changing demographics in the population, leading to increased longevity have led the people having medical conditions which predispose to a medical emergency or taking medication may influence their dental management and persons aged above 65 years or over are considered to be taking medication with a potential effect on dental care . An increasing proportion of the population is medically at risk. According to the European resuscitation council, sudden cardiac arrest is a leading cause of death in Europe, affecting about 7, 00,000 individuals a year .Thus, an effective management of an emergency situation in the dental office is ultimately the dentist's responsibility.(2) Although a number of studies have been carried out which sought to ascertain the emergency drugs and equipments, the lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legation action . For this reason, as health professionals, dentists should be well prepared to collaborate with the medical emergencies. (3) Providing basic life support (BLS) is the dentists' most important contribution until definitive treatment for a medical emergency can be provided .Few studies described how the dentists consider themselves in managing medical emergency situation and very few studies to our knowledge have reported studies involving fresh dental graduates . The aim of this study is to learn the experience of handling medical emergencies, their skills and competency and how well they felt are prepared to manage such events with appropriate use of drugs and equipments in a dental setting.(4)

Material and Methods

A cross sectional questionnaire approach was chosen to probe dental graduates' (Interns) knowledge, experience and perceptions of medical emergency in the dental office. This research was conducted at Saveetha dental college , Chennai, during the academic year 2016. A total of hundred and five (100) Bachelor of Dental Surgery graduates from the respective Saveetha dental college,who were undergoing the

Internshipand who could look back over their experiences regarding the dental-medical emergency were volunteered to participate, with an invitation issued in the college. Respondents were told the study was completely confidential and encouraged to answer a 7 item pretested questionnaire (6 closed ended and 1 open ended) which was in a tick box format.Data collection procedures followed the standards of the Saveetha dental college students and all the graduates (Interns) signed a consent form.(22) The purpose of this study was to evaluate the dental graduates, knowledge, experience, and perceptions regarding medical emergencies in the dental practice. The questionnaire sought information on the frequency and type of medical emergencies encountered by the interns in the past 4 years.The knowledge, confidence of administering the essential drugs and equipments required to be in the emergency drug box (8). The amount of medical emergencies training undertaken by participants on the past 4 years and what percent of this was basic life support training (9). If participants felt that more training of general medical emergencies is required. Data were collected from various aspects.

Results

Hundred dental graduates answered the questionnaire. Sixty-one (61) of hundred and five (58.1%) had experienced an emergency situation during their graduation. Syncope / faint was seen by 40.9% of the respondents, 37.1% with hypoglycemic attacks, allergic reactions by 17.1%, epileptic attacks by 7.6%, asthmatic attacks by 4.5% and angina 0.9%. The frequencies of the emergencies encountered were once or even more. (Table 1 & 2) shows the percentage of dental graduates about the knowledge of identifying the recommended drugs, essential pieces of equipments in the emergency kit and the confidence of using them. (21) Forty- five out of hundred (42.9%) had received no medical emergency training, and the remaining sixty (57.1%) had received a medical emergency and basic life support (BLS) training for less than 5 hours. Hundred and two graduates (97.1%) felt the need for more medical emergencies training. (Table 3) shows the competency in the areas of drug administration/other procedures. From an open ended question, we observed that the knowledge of the dental graduates (Interns) was at an acceptable level as majority of them expressed to terminate the treatment and activate the emergency services (EMS) when any emergency situation in the dental office occurs. (20)

Table 1: Essential drugs recommended being present in the drug kit and the level of confidence in using them

(In percentage)

Drug	**Yes**	**No**	**Unsure**	**Confident**	**Not confident**
Adrenaline	96.4	40.3	-	90.5	30.2
Aspirin	56.2	79.5	36.3	62.5	40.3
Glucagon	45.3	50.3	40.5	70.7	45.3
Glyceryltrinitrate	62.7	48.6	20.6	2.7	38.4
Prednisolone	57.3	59.7	39.5	3.5	60.3
Chlorpheniramine	66.2	49.3	45.6	2.8	50.3
Salbutamol	90.6	21.6	12.9	13.3	23.5
Glucose	80.8	12.4	13.7	89.6	4.6
Hydrocortisone	56.3	11.5	15.9	5.7	89.7
Midazolam	78.4	20.4	34.6	54.7	45.6
Dextrose	98.4	40.3	4.5	80.5	67.3
Oxygen	99.2	3.6	4.8	50.3	4.8
Atropine	90.6	23.5	45.6	3.6	59.6

Discussion

The results of this study confirmed that the dental graduates (Interns) are not capable of competently managing a medical emergency and perceived a need for more intensive education in medical emergencies, and they strongly desire to obtain this knowledge (5,10).Several studies have assessed qualified dental surgeons on management of medical emergencies, (4,11,12,13) but to our knowledge there is no reported study involving fresh Dental graduates (Interns). So this cohort was targeted to probe and quantify the perceptions of medical emergency in the dental office. Although there have been relatively few studies carried out regarding medical emergencies in dental hospitals, our study results show that the proportion of specific medical emergency events occurring were similar with those studies (9,11,14). The most commonly encountered emergencies seen by the Interns in both the colleges were syncope/faints, followed by asthmatic and hypoglycemic attacks.(18)This would indicate that the training should be focused on dealing with these emergencies. A higher frequency sixty one (58.1%) respondents had faced a life threatening situation in the

study contrary to the studies (3,8,11). The reason for differences in the frequency/ total number of emergency could be explained by having several persons reporting the same event occurring in the dental school more than once.(17) There has not been any published data regarding emergency drugs and equipments recommendations against which we can compare our results. The guidelines differ in recommended drug and equipments, but when a direct comparison is made between commonly recommended emergency drugs conclusions can be drawn. We found that respondents in our study had a good knowledge in identifying the four common drugs like adrenaline,glucose, oxygen and glycerlytrinitrate. The knowledge was not at an acceptable level, particularly when discus-sing drugs like Midazolam, prednisolone and chlorpheniramine maleate and very few respondents recognized these as being essential drugs (8,9) (Table 1).Similar results were found when investigating level of knowledge regarding emergency equipments. Single use syringes, oxygen face mask and blood glucose measurement device were recognized to some extent and lowered knowledge was seen regarding equipments like pocket masks, portable suction and self inflating child and adult bag valve mask (9,15) (Table 2).The confidence in the use of drugs and equipments mentioned were at a very lower level than the knowledge for all the drugs and equipments mentioned.(19) This suggests that although training is received in the theoretical aspect of emergencies, participants are not particularly confident to treat emergencies and may require further practical training (Table 1, 2 &3).From the responses regarding the number of hours of medical emergencies training undertaken in the under-graduate curriculum, it is evident that there are more definitive guidelines regarding the number of hours of training is recommended. Only 57% of respondents had undergone medical emergency and basic life support (BLS) training for less than 5 hours which was very low. The result may be due to the lack of definitive guidelines about the training with medical emergencies in the dental curriculum (9).Overall in the study, a large number of graduates stated that they did not know how to proceed in those situations even though they received training in the management of medical emergencies at some time, they expressed the need for further medical emergencies training (3,5,8,9,11,16).

Table 2: Essential equipments recommended being present in the kit and the level of confidence in using them.
(In percentage)

Drug	**Yes**	**No**	**Unsure**	**Confident**	**Not very confident**
Oxygen face mask	95.3	2.1	-	90.3	-
Single use syringe	56.3	46.2	2.5	32.3	30.2
Oropharyngeal airway	76.3	60.3	35.4	40.5	2.3
Pocket mask	65.3	50.2	5.7	21.4	4.5
Self inflating child and adult bag valve mask (Ambu bag)	79.3	32.5	11.3	34.2	12.4
Portable suction	68.5	40.2	2.3	45.3	2.3
Blood glucose measurement device	30.2	80.5	6.2	67.4	25.7
Automated external defibrillator	79.2	30.2	3.2	80.3	18.4

Table 3: Do you feel competent in the following areas.?
(In percentage)

Area	**Yes**	**No**

Administration of intravenous drug	30.5	32.5
Intramuscular injections	50.3	32.3
Maintaining an airway	78.3	23.6
Using an Ambu bag / bag valve mask	45.6	27.3
Using a glucose meter	35.6	78.5
Using a defibrillator	50.3	12.3
Administering oxygen	89.7	20.7

Conclusion

The study showed that syncope is the commonest medical emergency event and the others are hypoglycemic attacks, allergic reactions, epileptic attacks and asthma-tic attacks. All in all, dental graduates had a superficial knowledge of medical emergencies, drugs and equipments and they expect this topic should be an integral part of their curriculum.[10]A majority of them perceived the need for further training by means of hands on courses. The study has allowed to find deficiencies in the way the dentists were trained dealing with medical emergencies and identify a need for improvement, be by increasingthe volume and quality of training which undergraduates perceive in order to enhance their capability to recognize and manage a medical emergency and to become well qualified practitioners.[7]

Abstract

Introduction: Dentist encounters medical emergencies in their clinics which can be life-threatening.These emergencies should be treated immediately and cannot be avoided or referred,because they put the life and health of patients at risk.Therefore, the aim of this study was to evaluate how well dentist understand medical emergency during dental treatment.
The aim of this research is to evaluate the knowledge, experience and perceptions about medical emergencies amongst dentists in Chennai, India.

Materials and Method: Data was collected from 50 dentists of Chennai at self convenience using a structured questionnaire consisting of 10 item questionnaire.The sample was selected based on certain inclusion and exclusion criteria.Inclusion criteria includes postgraduate, South Chennai dentists.Exclusion criteria includes students,dental assistants.

Result: The study reveals that 60% the dentists in Chennai were confidently able to deal the life threatening emergency situations whereas 100% of dentists have knowledge how to manage the life threatening emergency situations.

Conclusion: Based on the above study it can be concluded that the level of training and level of knowledge on medical emergencies of the dentist in Chennai are good but not upto the desirable standard.

Key Words: *Medical emergencies, dental graduates, basic life support, emergency drugs.*

Introduction:

Every dental health professional should have the essential knowledge to identify, assess and manage a potentially life-threatening situation.Dentist encounter medical emergencies in their clinics which can be life threatening.These emergencies should be treated immediately and cannot be avoided or referred,because they put the life and health of patients at risk.(1) Professional bodies usually have its own code of conduct for their members.(2)The code of ethics for dentist, toward patients and public was standardized by the Dental Council of India, "Treat the welfare of the patients as paramount to all other considerations and shall conserve it to the utmost of his ability."(3)In 1971–1972, health professions education worldwide was assessed by the World Health Organization commission and the commission concluded that education and health service system are inextricably interwoven with each other and questions about the training of health-care providers follow soon after when questions arise about the delivery of service.(4)Dental professionals are expected to provide safe and painless dental procedures when they complete their education from dental colleges. Undergraduate dental education's aim has been described as "to produce a caring, knowledgeable, competent, and skillfull dentist who is able, on graduation to accept professional responsibility for the effective and safe care of patients who appreciates the need for continuing professional development, who is able to utilize advances in relevant knowledge and techniques and who understands the role of the patient in decision-making."(5)A medical condition demanding immediate treatment is an emergency.

Medical emergencies have many forms including syncope, asthmatic attacks, epileptic attacks, cardiac arrest, etc(6).In dental offices, medical emergencies do occur. A survey was conducted among 4000 dentists by Fast and others, and the results of the survey revealed that for 10 years 7.5 emergencies per dentist was reported.(7)A total of 13,836 emergencies were reported within a 10-year period in a survey conducted among 2704 dentists throughout North America.(8)It is mandatory that every dental health professional should have basic knowledge to manage a potentially life-threatening situation. A study was conducted in Japan between 1980 and 1984 by the Japanese Dental Society and it was reported in the study that anywhere from 19% to 44% of dentists had a patient with a medical emergency in any 1 year(9)and about 70.2% of general dental practitioners in the United Kingdom have managed medical emergency even.(10)One study conducted in Australia reported that approximately 15% of dental surgeons had done cardiopulmonary resuscitation (CPR) for the patients in their dental offices in 1 year.(11)

Although a number of studies have been carried out which sought to ascertain the emergency drugs and equipments, the lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legation action.Changing socioeconomics in the populace, prompting expanded life span have driven the general population having therapeutic conditions which incline to a medicinal crisis or taking solution may impact their dental administration and people matured over 65 years or over are thought to produce drug

with a potential results on dental care.An expanding extent of the populace is therapeutically in danger. According to the European resuscitation council, sudden cardiac arrest is a leading cause of death in Europe, affecting about 7, 00,000 individuals a year.(13)For this reason, as all the health professionals, dentists must be well prepared to attend to and collaborate with the medical emergencies .Providing basic life support (BLS) is the dentists' most important contribution until definitive treatment for a medical emergency can be provided(14). Few studies have assessed how competent dentists consider themselves in managing medical emergencies, and very few studies to our knowledge have reported studies involving fresh dental graduates.(15)In a study conducted by Gupta *et al*it was reported that less than half (42.1%) of the dentists received training during their undergraduate and postgraduate education.(12)The lack of training and inability to cope with medical emergencies can cause tragic consequences and sometimes legation action.(10).Hence, as all the health care professionals, dental care professionals must be well prepared to manage medical emergencies.

Therefore, the aim of this study is to learn the experience of handling medical emergencies, their skills and competency and how well they felt are prepared to manage such events with appropriate use of drugs and equipments in a dental setting.

Materials and Method

Data were collected from 50 dentist in Chennai using a structured questionnaire consisting of 7 item questionnaire (6 closed and 1 open ended).
The sample was selected based on certain inclusion and exclusion criteria.
Inclusion criteria:
1. Postgraduate
3.South chennai dentists.

Exclusion criteria:
1.Students
2.Dental assistants.

Results

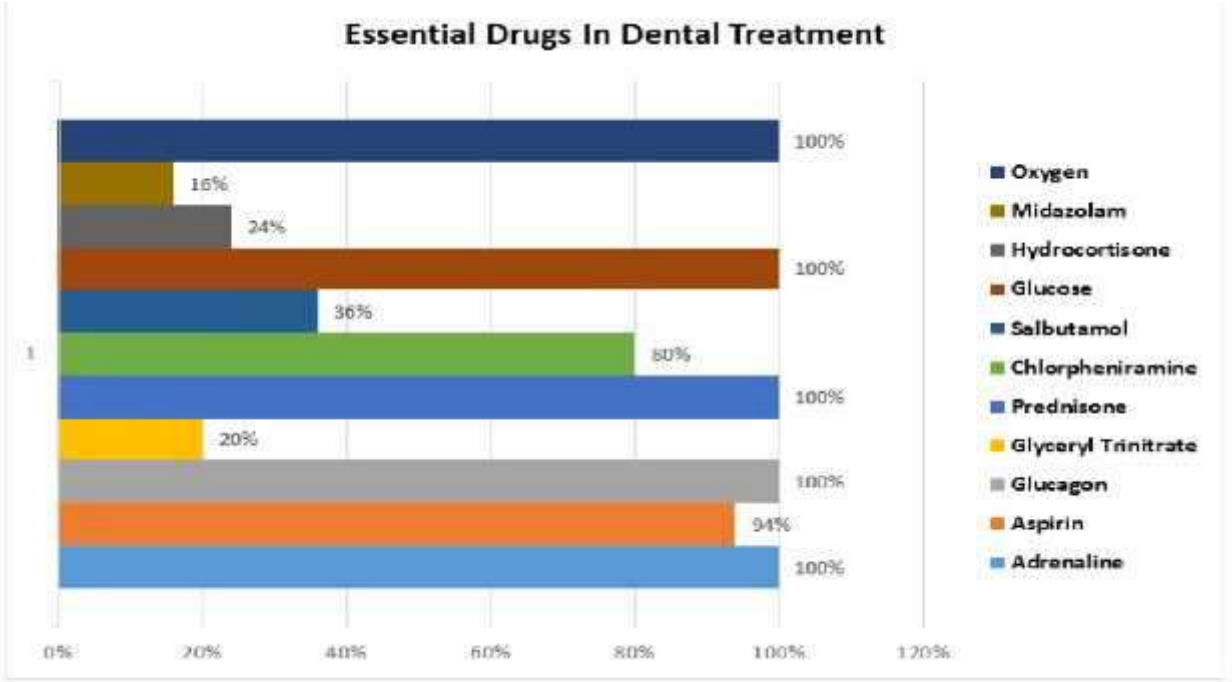

Figure 1: Shows the percentage of dentists about the knowledge of identifying the recommended drugs in their emergency kit.

Figure 2: Shows the percentage of dentists confidence of using the recommended drugs in their emergency kit.

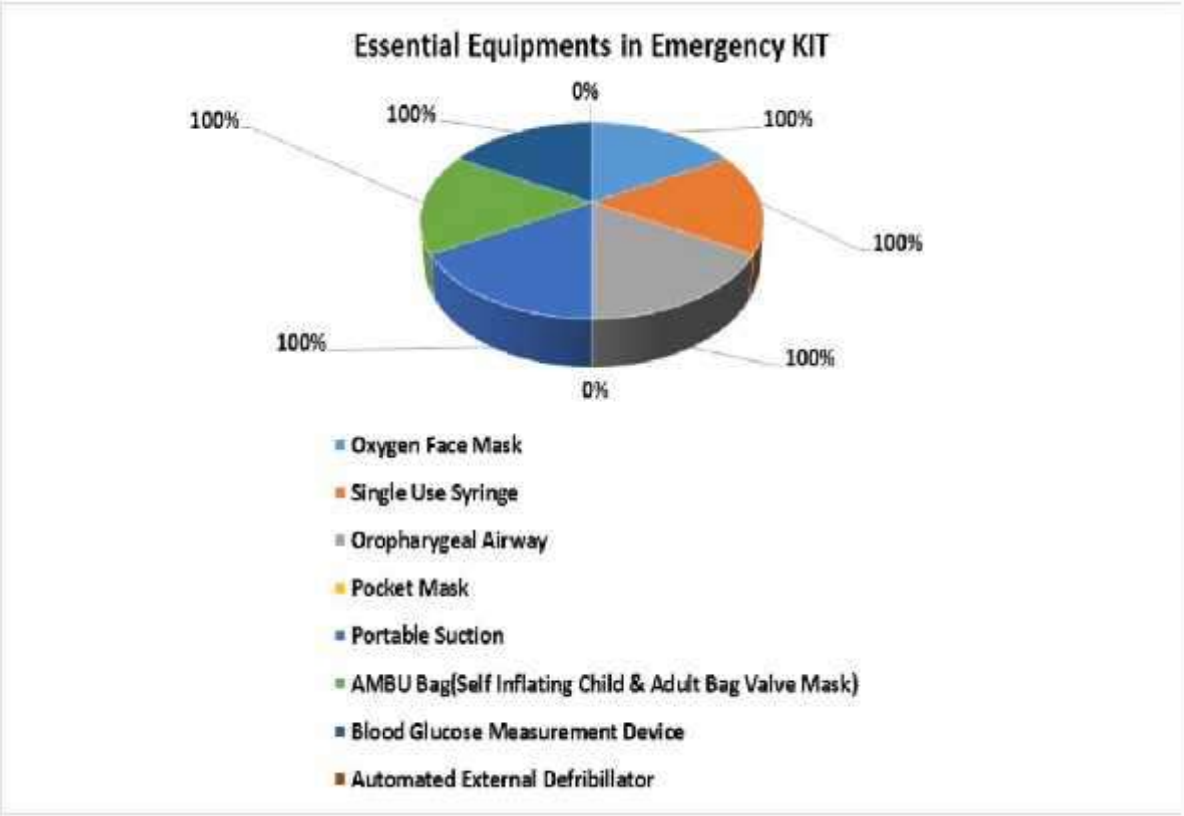

Figure 3:Shows the percentage of dentists about the knowledge of essential pieces of equipments in the emergency kit.

Figure 4: Shows the percentage of dentist's confidence of using essential pieces of equipments in the emergency kit.

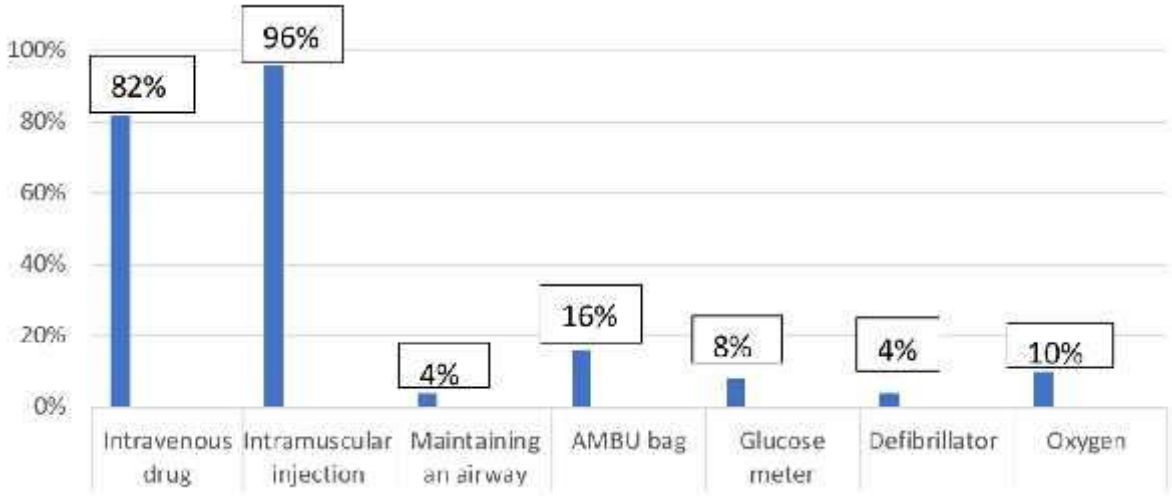

Figure 5: Shows the competency in the areas of drug administration/other procedures.

Discussion

Medical emergencies have been reported to occur frequently in dental practice.(16) Fortunately, serious medical emergencies in dental practice are not common but they are all the more alarming when they occur.(17) A thorough patient history can draw the practitioner's attention to potential medical emergencies that could occur.(16) Dental professionals most important contribution is to provide BLS to the patients until absolute treatment for medical emergency situations. Data obtained from dentists in independent studies by Fast et al and Malamed et al report that the dental office environment is not immune to the occurrence of potentially life threatening.In a 10 year period, more than 30,000 emergencies were reported by more than 4,000 dentists, Junaid Ahmed et al surveyed the nature of the emergencies varied significantly, from syncope to cardiac arrest and anaphylaxis. It is believed that the overwhelming majority of emergencies encountered were precipated by the increased stress that is so often present in the patient in the dental environment. Increased stress can result from fear and anxiety or inadequate pain control (18-19). Stress is associated with an increased occurrences of emergency situations was also reported by Matsuura et al who reported that 77.8 percent of life threatening systemic complications in the dental office developed either during local anaesthetic administration or during dental treatment. (20)

The above data dictates the need for the dental surgeon to be trained to promptlyrecognise and efficiently manage emergency situations.Our study showed knowledge about medical emergencies among the dental graduates. They hand the best knowledge was about handling syncope, diabetic emergencies and asthma and the knowledge about cardiac arrest was very minimal. Birang et al in their study showed that the knowledge score of Esfahan dentists was

5.42/10(21). Gupta et al stated that the knowledge of dental surgeons from Udupi and Mangalore, Karnataka was from moderate to poor(22).Regina M et al, in their study stated that dental students have little understanding about medical emergencies (23). The knowledge of Mashhad dentists was also poor as stated in their study conducted in the province of Iran (24). These results indicate a need for a revision in the curriculum of dental graduate studies. The dental graduates in our study showed a good level of confidence in checking carotid pulse, performing Heimlich maneuver, cardio, pulmonary resuscitation and artificial respiration. We believe that though the knowledge level is adequate what the graduate ack is in the skills. In the present study a large number of graduates stated that they did not know how to react in those situations even though they received training in the management of medical emergencies at some time in their curriculum.

From the responses regarding the number of hours of medical emergencies training earmarked in the undergraduate curriculum, it is evident that there is a definite need to increase the number of hours spent of emergency management. Only 54.7% of respondents had undergone training in medical emergency and basic life support (BLS) training. Providing basic life support (BLS) is dental surgeons most important contribution until definitive treatment for a medical emergency can be given. The purpose of BLS is to prevent inadequate circulation or respiration thorough prompt recognition of the problem and intervention to support a victims circulation and respiration through CPR (25). However a number of studies have found that about half the dentists from all over the world are notable to perform CPR properly (26-28). The result may be due to the lack of definitive guidelines from the regulatory bodies about the training with medical emergencies in the dental curriculum. In the dental curriculum, management of medical emergencies in dental practice comes under the syllabi of general medicine and oral surgery (29). The exact duration and the methodology has not been specified, which needs to be updated to enable students to develop a confident approach towards handling medical emergencies.

The dental graduates expressed the need for further medical emergencies training and were prepared to be life long learners about the topic at hand, and expressed their willingness to attend continuing professional development programs by which they can update their knowledge about medical emergencies. Our result was in accordance with other studies done in the same field (30-35). The confidence in the use of drugs and equipment mentioned were at a very lower level than the knowledge for all. The drugs and equipment mentioned. This suggests that although training is received in the theoretical aspect of emergencies, participants are not particularly confident to treat emergencies and may require further practical training. Athereton JS's study suggested that up to 44% of dentists may have a patient with a medical emergency in a year. The result of this study also reflect that medical emergencies occur quite frequently because more that n half of the dentists claimed to have previously encountered medical emergency during their training(36). The result of this study suggests that a deficiency in dental academy's curriculum on medical emergencies. A

curriculum refers to the overall content of what is to be taught about a subject matter.Guidelines are in place for the management of medical emergencies in a dental setting and the purpose of these guidelines is to set out agreed philosophy and responsibilities of all dentists in relation to resuscitation and management of medical emergencies in the dental surgery (37). Other important points revealed by this study are that only the theoretical training in medial emergencies seems to be effective.

This study also suggest that the dentists may not be prepared to handling medical emergencies effectively because major claimed not to have been taught how to perform many of the potentially lifesaving procedures. Dentists are members of the medical profession and should be confident in dealing with emergencies which may arise during their work. This result is similar to what was reported among a group of medical students where 85.3% of them had never take any basic life support course (38). Prevention and preparation are often the best antidotes for an emergency. Beginning by obtaining a good health history at the patient's past and present health status. It should also include questions indicating problems the patient may not be aware of , but which may alter treatment. A list of medication names and dosages that are currently prescribed to the patient should be ascertained(39).The result of this study amplifies the need to ensure that this recommendation is taken very seriously.

Conclusion

Based on the above study it can be concluded that the level of training and level of knowledge on medical emergencies of the dentist in Chennai are good but not upto the desirable standard.The study has allowed to find deficiencies in the way the dentists were trained dealing with medical emergencies and identify a need for improvement, be by increasing the volume and quality of training which they perceive in order to enhance their capability to recognise and manage a medical emergency and to become well qualified practitioners.Since they are dealing with the life threatening situations, it is therefore necessary to put proper strategies in place, such as the development of the practical model, to improve the areas of weakness this study identified.for the patients in their clinic and they should be well knowledgeable and trained to deal with the emergency situations in the dental office.

Abstract

Introduction: Rehabilitation of patients with complete Edentulousnessare more complex in prosthetic dentistry because of its psychosocial, aesthetic and functional implications. Teeth serves as a part of the masticatory system and it mainly contributes to phonetics, functions and aesthetics. To evaluate the patient's experience and overall satisfaction with surgical and prosthetic procedures with implant over denture and conventional complete denture.

Materials and Methods:A questionnaire based survey was conducted. Questionnaire was prepared based on the aesthetic, function and comfort level of the patient. 30 patients were randomly selected who undergone treatment for completely edentulous condition.

Result: The purpose is to know the different opinions of the patients regarding the prosthodontics treatment so that efforts can be taken to produce better results and satisfaction. Patient’s feel economically complete denture (70%) is better than implant supported over denture (30%) because the implants are cost effective. Based on function, implant supported over denture was 70% higher than complete denture which was 30%. Hence the overall satisfaction in this study was better in implant supported over denture (60%) than the complete denture (40%) because they play important role with retention.

Conclusion : The comfort level with implant retained over denture is superior to the conventional complete denture. Aesthetics, functions are comparatively good in both conventional complete denture and implant retained over denture.

Key Words*: experience, satisfaction, conventional complete denture and implantover denture*

Introduction

Great improvements in medical field have greatly increased average human life expectancy, indicating that patients now have greater chances of turning into completely edentulous. For edentulous patients who receive dentures, providing enough stability and support for the dentures is not sufficient, instead,acceptance of dentures by the patients to endure a process of adjustment. The patient encounters more difficulties when they wear complete dentures for a longer period of time because the ridges are atrophied [1]. This kind of atrophy becomes worse when thepatients are wearing a mandibular complete denture because of the tongue mobility issues and decreased contact surface. Many other problems when combined such as related to neuromuscular coordination and the denture's ability to form a tight seal with the surrounding soft tissues, patients will show much more dissatisfaction with the complete dentures especially mandibular dentures [2].

Since then Brånemark's success towards titanium root-form dental implants, when dental implant therapy has given new hope for edentulous patients. Dental implant treatment provides patients with better stability and increased biting .Rehabilitation of patients with complete Edentulousness are more complex in prosthetic dentistry because of its role as comfort, aesthetic and functional implications. Teeth serves as an important part of the masticatory system and it mainly concerned with phonetics, functions and aesthetics [3,4].

The psychological variations in patients due to tooth loss leads to little concern, when most of them adapt to replace the missing in the form of bridges, crowns and dentures[5]. Implants play an very important role to have greater retention and stability of the complete dentures, thereby initiating efficient functioning, psychological and fixed partial reconstructions to avoid the need to prepare intact adjacent teeth [6,7]. Additional factors involved may be preventing continuous alveolar bone resorption, by preserving ridge height and width, and improving aesthetics and comfort in anterior regions [8, 9].

Many of the studies have focused on the osseointegration [10, 11, and 12] through the clinical aspect without considering patients' attitudes towards implant treatment and their suggestions about aesthetics, function, comfort and satisfaction. The present study evaluates patients' satisfaction and experiences of surgical and prosthetic procedures as well as their opinions regarding function, aesthetics and comfort.

Conventional complete denture prostheses have been commonly used for the missing dentition replacement. Complete denture fabrication and techniques have advancements and has been improved over the years; however some attention has been paid towards the psychological impact of the patient before and after receiving the prostheses. Psychological factors play an important role which provides valuable information for the satisfactory outcome of complete denture treatment. Various other factors like mastication and speech also contribute to the success of this treatment.Force with the prostheses [3, 4]? However, for some edentulous patients with certain unfavourable oral conditions or financial concerns, support for fixed partial dentures is not feasible. Therefore, over dentures retained or supported by implants have been adopted [13, 14, 15].

In general, implant-retained over dentures can be applied over placing as few as one or up to many implants and then using attachments to provide retention to the denture [14, 15, and 17].

The critical concerns for frequently denture-wearing patients are related to appearance, speech, occlusion, and Masticatory functions [16, 17, 19]. It is common for clinicians to use intraoral conditions as gingival and periodontal health, and prosthesis condition to examine the treatment outcome [18, 19].However; these conditions do not completely reflect the definite needs of patients [17].

Dentists focus on each patient’s needs regarding the usage of dentures, including their need regarding comfort levels, appearance, feeling, function, speech, and the patient’s confidence, in order to estimate patient satisfaction [20, 21] The final goal was to achieve a standard, such that edentulous patients are completely satisfied with the treatment and have a better understanding of the impact of edentulouson the their quality of life. A good dentist has to consider the given patient’s specific requirements. In the view of most dentists, the survival rate of dental implants, the life span of dentures, and treatment complications are the most important considerations. However, what patients are concerned about the most are how many benefits the treatment will provide and whether the costs are worthwhile. Moreover, considerations of how the treatment could possibly affect the patient’s social life and mental well-being are paramount. Therefore, dentists should evaluate a given treatment with

function, aesthetics, and the patient's feelings and expectations in mind [24].

Materials and Method

30 edentulous patients who undergone treatment for replacement were randomly selected from the database in Department of prosthodontics, Saveetha Dental College, Chennai. 12 edentulous patients have implant retained over denture. 18 patients have conventional complete denture. Questionnaire was prepared based on the aim and objective of the study. After obtaining their written consent to participate in the study, the questionnaire was filled in consultation with the patient. The detail regarding the newly constructed prostheses was recorded as it was reported by the patient. The patient was encouraged to give frank opinion about his/her new denture and was assured that the identity would be kept confidential. The questions were asked in his/her own mother tongue. Once the questionnaire was completed for 30 patients, they were grouped based on the scale of fair,satisfied,good,excellent for different parameters like i) Functioning, ii) aesthetics, iii) comfort iv)) overall satisfaction for maxillary and mandibular dentures.

Questionnaire:

1) When did you lose your teeth?

   A) 1 MONTH AGO B)6 MONTHS AGO C)MORE THAN ONE YEAR

2) How did you lose your teeth?

   A) TRAUMA B) CARIES C)MOBILITY

3) Did you visit the dentist immediately after losing your teeth?

   A) YES B) NO

4) Do have any previous experience with dentures. If yes, what prosthesis?
   A) YES B) NO

5) Have you any idea about fixed prosthesis?
   A) YES B)NO C)NO IDEA

6) Have you any idea about over dentures?

A) YES B) NO C)NO IDEA

7) Which prosthesis would you prefer?

A) CONVENTIONAL COMPLETE DENTURE
B)IMPLANT OVER DENTURE
C)NO IDEA

8) Why do you prefer your decision?

A) ECONOMIC B)AESTHETIC C)COMFORT

9) How efficient do you think your denture is?

A) FAIR B) SATISFIED C)EXECELLENT

10) Are you satisfied with the aesthetics?

A) FAIR B) SATISFIED C)EXECELLENT

11) How is the denture functioning?

A) FAIR B) SATISFIED C)EXECELLENT

12) How is the comfort level of the denture?

A) FAIR B) SATISFIED C)EXECELLENT

Results

Fig-1 Shows satisfaction and experience of complete denture.50% of the population are concerned about the cost effective factor. 20% shows satisfaction towards aesthetics and function. 10% of the complete denture wearers are satisfied with the comfort level.

Fig-2 showssatisfaction and experience of implant overdenture.30% of the population shows satisfaction towards aesthetics, function and comfort. 10% of the patients wearing implant supported over denture are satisfied with the cost.When comparing the overall satisfaction among implant supported over denture and conventional complete denture, the comfort level with implant supported over denture shows higher satisfactory level (bar chart). When comparing satisfaction of the aesthetic factor and function, the implant supported over denture are significantly better than conventional complete denture. Treatment option for complete edentulous patients ranges from removable prosthesis and fixed prosthesis. Due to cost factor fixed prosthesis retained with implants are less popular in patients. Moreover the fixed prosthesis with implants is technique sensitive and needs multidisciplinary approach. This causes prolongation of treatment time. The conventional complete dentures are chosen to reduce the treatment cost as well as the treatment time.

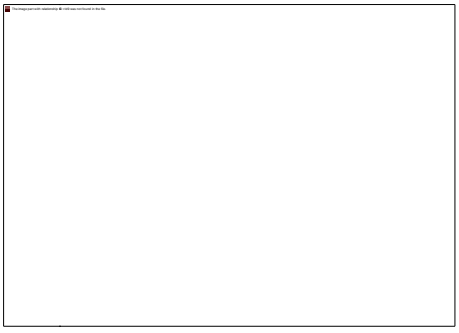

Figure 1: Satisfaction and experience of complete denture

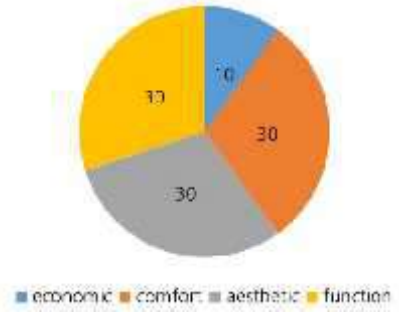

Figure 2: Satisfaction and experience of implant over denture

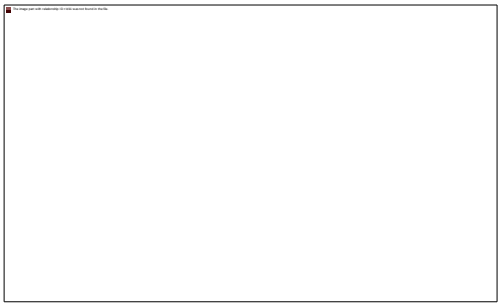

Figure 3: Comparison of conventional complete denture and implant supported over denture based on aesthetics, Comfort and function

Table 1: Patients overall satisfaction over conventional complete denture and implant supported over denture

	Complete denture	Implant retained overdenture
Economic	70%	30%
Comfort	20%	80%
Aesthetic	35%	65%
Function	30%	70%
Satisfaction	40%	60%

Discussion

The survey shows overall satisfactions with implant retained over denture are better. The comfort level between the two shows very significant variation. The treatment option of Implant supported over denture cannot be suggested for medically compromised patients. In residual ridge resorption patients, especially in mandible the retention and stability of complete denture are compromised. In this situation implant retained over dentures are suggested. Patient's feel economically complete denture (70%) is better than implant supported over denture (30%) because the implants are cost effective. Based on comfort, implant supported over denture was 80% higher than complete denture which was 20%. Based on aesthetics, implant supported over denture was 65% higher than complete denture which was 35%. Based on function, implant supported over denture was 70% higher than complete denture which was 30%. Hence the overall satisfaction in this study was better in

implant supported over denture (60%) than the complete denture (40%).

No gender-based difference was observed in our study. However, some previous studies have indicated that male patients are more satisfied than female patients. One possible reason for this difference is that most females are much more aware of pain and operations. Therefore, non-surgical treatments will be the first choice for elderly female patients [22].
Most previous studies on patient satisfaction have only reported the average age of the participants, but differences in satisfaction levels among different age groups have not been

In terms of masticating ability for different food types, soft foods had the best score while hard and sticky foods had the lowest score. Similar results have been found in most other studies. Awad studied 102 patients (48 wearing complete dentures and 54 wearing mandibular implant-retained over dentures) and applied VAS to evaluate the masticating ability for different food types.

In 2002, Raghoeber showed that mandibular implant-retained over dentures were comparatively better than complete dentures in the first and fifth years after treatment, both in performance of the clinic and satisfaction of the patient. For placing the mandibular implant-retained overdentures,showed a better score than the complete dentures in the tenth year, although the difference was less significant [23].

In 2004, Timmerman published a randomized con- trolled trial study comparing two mandibular implant-retained over dentures with a ball or bar attachment to a four mandibular implant-supported over denture with three bar-and-clip attachments.(26)Although there was no significant difference among these three treatments, patient satisfaction in terms of retention and stability with the mandibular four implant-supported over denture was much better than for the other treatments after 8 years. This result also demonstrated that this design was more stable [24].

A similar result was found by Heydecke in an analysis of 60 seniors (30 with complete dentures and 30 with implant-re- tained over dentures). According to an analysis of mental and social ability using the OHIP-20 (oral health impact profile), patients wearing mandibular implant-retained over dentures had better performance.

Complete edentulous is related with decreased masticatory function, as well as unfavourableaesthetics’to loss of support for the musculature of face, reduced vertical dimension, and impairment of speech. The conventional method for treating edentulous patients is to provide them with conventional complete dentures. And also denture must be adjusted overtime for progressive tissue changes related with denture wearing. Patients who wear conventional dentures complainabout the instability of the prosthesis, particularly the mandibular denture due to retention. Denture instability leads to a feeling of insecurity, inefficient mastication, and overall dissatisfaction with the denture. Many recent advances in implant dentistry have allowed a change from conventional complete denture to implant-supported overdenture for oral rehabilitation of edentulouspatients [25].The McGill consensus statement in 2002 and some other studies states that the mandibular implant over dentures should be the first treatment of choice for edentulous patients. Implant-retained over dentures have many advantages over conventional complete dentures as chewing efficiency, masticatory bite force.

Chewing replaces the body's nutrients, thereby facilitating the maintenance of the body composition. Mastication is the first step and consists of a rhythmic separation and apposition of the jaws and involves biophysical and biochemical processes. Although data on the importance of chewing on various stages of digestion are very much limited, it has been concluded that the chewing efficiency as low as 25% adequate for complete digestion of food. Patients do not, however, have alternative smaller number of teeth by more prolonged o number of chewing strokes; they hardly swallow large food particles. Hence, loss of teeth can lead to a reduced chewing efficiency, and there is known factor of restricted dietary choice with systemic effects. Clinical experience suggests a relationship between the quality of prosthetic service and denture wearers chewing performance. Dentures move during mastication because of dislodging forces of the surrounding the muscles[27].These movements manifest themselves as displacing, lifting, sliding, tilting, or rotating of the prosthesis. Mandibular implant overdenture helps in better stability, support, and retention which reduces the denture movements and furthermore helps in achieving better chewing efficiency and masticatory bite force. The masticatory performance is reduced to one-fourth to one seventh of the performance of dentate subjects, depending on age and type of food. Thus, denture wearers need seven times more masticatory cycles to reduce food to half of its

original size [29,30]. Reported masticatory bite forces using complete denture is much smaller than those produced by natural dentition which is of the order of 200 N. Although maximum bite forces of 60–80 *N* have been reported for complete dentures and 150–170 *N* for implant-supported overdenture [28]. Edentulism is affiliated with anatomical, functional, and psychologic changes in patients. In complete dentures, the absence of stability, retention, and reduced chewing ability are common oral findings accompanied by poor quality of life. The stated benefits of an implant overdenture include bone preservation, improvement in masticatory ability, masticatory force, increased stability and retention, and significantly higher patient satisfaction. There is a great variety of methodologies describing chewing efficiency.

Complete dentures (CD) are the traditional form of treatment for the edentulous patient, and despite a number of limitations, they are still commonly used today.However, due to a lack of predictable outcome and variation in the patient's ability to adapt to CDs [5] especially in the mandible, alternate forms of treatment have been developed, With the advent of osseointegrated implants in the early 1980s, novel forms of treatment that possess greater retention and stability have been introduced; these include implant-retained mandibular over dentures (OD) and complete fixed dentures [13].

While comparing complete denture, implant retained over denture provides edentulous patients with a better quality life due to their greater retention and stability, increased level of function and aesthetics, and reduced alveolar ridge resorption.These features improve the patient's inability to chew and speak, which are common complaints associated with CDs28].More recently, the use of OD for the treatment of the edentulous patient has been considered as the first choice in treatment for the edentulous mandible [31].

Most of the recent studies have focused on the clinical aspects of osseointegration [29, 30,31] without considering patients' attitudes toward implant treatment and their opinions about aesthetics, function, comfort and satisfaction.The importance of providing patients with high quality dentures should be self-evident, if for no other reason than to avoid harmful effects on the oral tissues [32].

Restoration of functions, esthethic and maintenance of patient's health are the basic objectives for an ideal complete denture therapy [33].During a patient's management, an

operator may be satisfied with the quality of work done by them, but the success of the treatment is determined by satisfaction[34].

Conclusion

The comfort level with implant retained overdenture is superior to the conventional complete denture. Aesthetics, functions are comparatively good in both conventional complete denture and implant retained overdenture.The comfort level with implant supported over denture is significantly better than conventional complete denture. In severe resorbed ridge situations implant supported over dentures are suggested.

Abstract

Introduction : Motivation is an impetus for patients to seek orthodontic treatment; it also affects adherence, treatment outcomes, and satisfaction towards orthodontic treatment. The aim of this study was to assess the lack of motivation of adult male patients or the other reasons responsible for not seeking orthodontic treatment, and classify the patients according to their reasons. Prejudiced notions about treatment and various fears have created a resistance or hesitation towards orthodontic treatment in men. The aim of this study is to assess the mind set and overall attitude of male adolescent patients toward not seeking orthodontic correction for malocclusion.

Materials and Methods :A questionnaire based study was conducted at the department of Orthodontics, Saveetha Dental College, a total of 50 male subjects with malocclusions requiring orthodontic interventions were selected for the study. Data was collected using a structured, self-administered questionnaire which was designed after reviewing recent articles, developments and also similar questionnaires that are based on the objectives of the study.

Results :69% of subjects were aware that they had a malocclusion whereas the remaining 31% were not aware. On asking as to why they were not correcting the malocclusion, 18% stated that it was embarrassing to wear braces, 4% stated that the treatment was too expensive, 19% stated that the treatment was that of a long duration, 7% felt they were too old for seeking orthodontic treatment, 6% had no interest to do the treatment, 9% stated it would painful, another 16% had concerns that food would get stuck to the braces, 21% were scared to undergo treatment.

Conclusion : The unwillingness of male adolescent patients for seeking orthodontic treatment is studied and the reasons are discussed. This will help in educating them on the long term

effects of malocclusion and to convince them for opting to go ahead with orthodontic treatment.

Keywords*: malocclusion, orthodontic intervention, braces*

Introduction

Orthodontic treatment is the process of aligning the teeth or correcting other irregularities, which thus improves health, function, appearance, and social well-being [1, 2]. Males are generally more concerned about the comfort rendered during treatment of their teeth. Understanding the factors that decide the requirement for orthodontic treatment will enable a more systematic planning and also better assessment of treatment needs and patient's priorities [3].

There is a lack of research on the motivation of adults seeking orthodontic treatmentespecially in men [4]. Both positive and negative motivations are correlated with adherence to treatment [5]. In orthodontic clinical practice, as well as in other dental specialties, treatment success does not depend solely on factors such as proper diagnosis, biocompatibility, and skill of the dentist but also depends on the patient's cooperation [6]. If the patient is not cooperative and does not follow the instructions given by the dentist it may lead to unsatisfactory outcomes of the treatment adolescence is a period when important physical, social, and emotional changes appear [7, 8].

The cooperation of the adolescent patients can be altered based on extrinsic factors (social stereotypes, gender, educational level, family) and the intrinsic factors (personality, temperament). The unwillingness of male adolescent patients with malocclusions for orthodontic treatment is studied so as to be able to educate them on the long term effects of malocclusion. Hence we can convince them for opting to go ahead with orthodontic treatment.Self-perception of orthodontic treatment plays a major role in bringing the patient to the orthodontist for treatment and the perception varies according to psychological status, basic knowledge of malocclusions and also perception changes according to the comments an individual receives from the surrounding people [9].

Social psychologists have described various theories on patient compliance. Many components of 'Health Belief Model' are applicable to orthodontic treatment situation. Variables like treatment-seeking behavior, personality type and barriers to action comply well with the compliance of the patient [10,11]. A compliant orthodontic patient may be described as a patient who practices good oral hygiene, follows appropriate diet, maintains

appliance without breaking, keeps regular appointments, and follows instructions of the doctor. The purpose of the present study is to evaluate the current perspective of Indian orthodontic patients towards not seeking orthodontic treatment.

Materials and Methods

A questionnaire based study was conducted at the department of Orthodontics, Saveetha Dental College, a total of 50 male subjectswith malocclusions requiring orthodontic interventions were selected for the study. Data was collected using a structured, self-administered questionnaire which was designed after reviewing recent articles, developments and also similar questionnaires that are based on the objectives of the study.

The questionnaire was divided into three parts. The first part included questions based on awareness of malocclusion, the second part consisted of questions related to their knowledge on sequelae of malocclusions and the final part consisted of an open question asking them to state out their reason for not undergoing orthodontic treatment. All questionnaires were anonymously collected and the data was kept confidential and not used for anything apart from the study purpose.

Questionnaire

This questionnaire was modified from the questionnaire of Ingervall *et al*. and Ng'ang'a *et al.* [12, 13]The questionnaire contained the following questions:

1. Do you find that your teeth are irregular (not straight)?

2. If your teeth are irregular, does this affect your::

3. If you think you need orthodontic treatment, why haven’t you done so yet?

Results

Figure 1 indicates, that69% of them were aware that they had a malocclusion whereas the remaining 31% were not aware.When asked about the sequelae of malocclusion, 48% of adolescent males pointed out the difficulty in mastication during orthodontic treatment while 24% said that food accumulation is a problem, 9% stated that compromised aesthetics was their concern and 19% were concerned of dental caries that could occur during treatment. On asking as to why they were not correcting the malocclusion, 18% stated that it was embarrassing to wear braces, 4% stated that the treatment was too expensive, 19% stated that the treatment was that of a long duration, 7% felt they were too old for seeking orthodontic treatment, 6% had no interest to do the treatment, 9% stated it would painful, another 16% had concerns that food would get stuck to the braces, 21% were scared to undergo treatment.

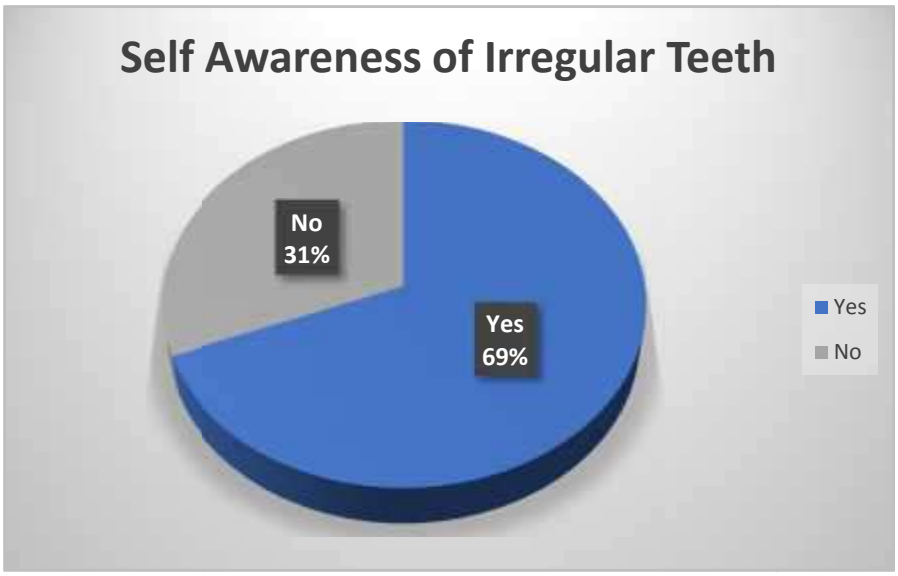

Figure1- Pie chart depicting self awareness of irregular teeth.

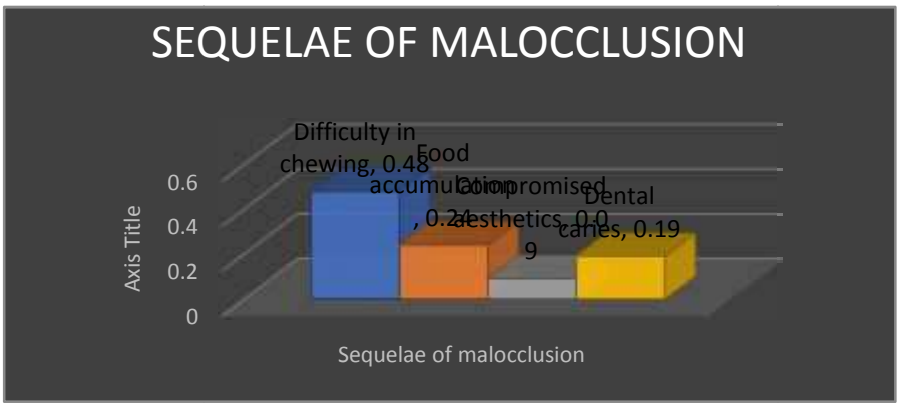

Figure 2- Bar chart of sequelae of malocclusion.

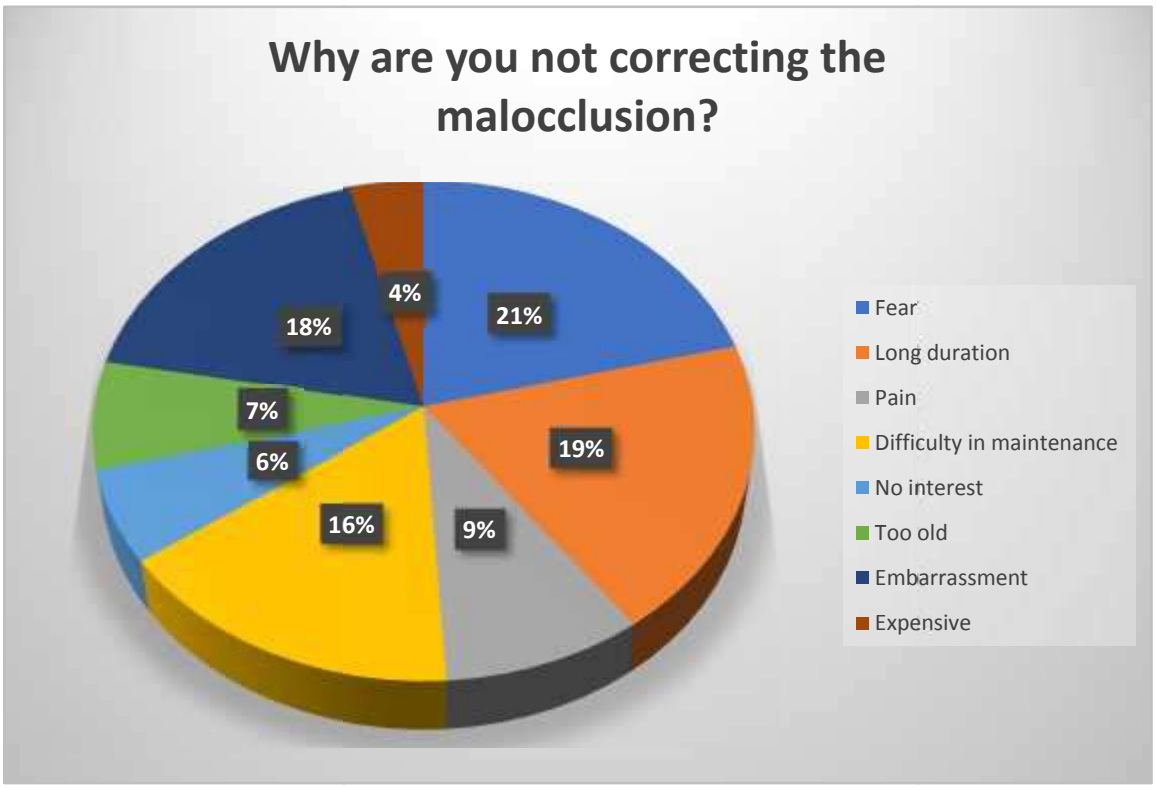

Figure 3- Pie chart of reasons for not correcting irregular teeth.

Discussion

Most adults who seek orthodontic treatment do so because they feel their smile is the most important feature of their facial appearance, and they wish to improve their smile to feel happier about their looks and enhance their self-esteem. Some have problems with their teeth

and gums, or they are just unhappy with their smile and the irregularity of their teeth. Other adults do so to improve their bite, chewing, or to make it easier to maintain good oral hygiene.

This survey conveyed that patients had satisfactory knowledge of whether they possess malocclusions or not as well as the sequelae of the same. When looking at the factors contributing to the negative attitude of patients in not seeking orthodontic treatment, fear, no interest and time constraints were the main concerns.Closely following were the concerns of difficulty in maintenance and embarrassment. The movement of teeth by orthodontic appliancestypically causes some discomfort to the patient. It has been reported that fear of pain is a key factor discouraging a patient from seeking orthodontic treatment [14].

In our study sample we conclude that for male patients, esthetics was not a major reason for seeking orthodontic treatment hence they lacked the motivation to seek orthodontic treatment and that can be a main reason for lack of interest towards orthodontic treatment.

In the study done byAl Zubair NM, the most common reason for not seeking orthodontic treatment in children was

1) Lack of awareness about orthodontic treatment;

2) Fear of pain and of tooth removal [15].The predominance of fear of pain is similar to that of Batayine [16] Al-Huwaizi [17] andGatchel [18].

Various studies identified female orthodontic patients as more cooperative than males [4-7]. The present study showed similar findings that maleadolescents were concerned more about pain and time duration of orthodontic therapy.

Egolf et al[5] studied history factorsassociated with compliance. These factors were considered as a combination of personality type, negative motives and positive motives. This study assessed the reason for patients not going forward with orthodontictreatment.The assessment on attitude of the patient was related to perception on treatment service, cost and also personal factors such as embarrassment.

The factors contributing to the above mentioned study vary from the present study due to variations in sample size and geographical variations.

These information are pertinent for better clinical management for service providers. It can help improve their service and enhance rapport with the patients. Actually, orthodontist's interpersonal behaviour and role in patient motivation is another aspect of successful orthodontic treatment. The orthodontist should give positive feedback and communicate with the patient on the issues of patient cooperation and their inconveniences. Orthodontists should explain about the appliance including retainers, and advice on oral hygiene, dietary control and appliance maintenance methods. Patients who are dissatisfied with the treatment and interpersonal aspects tend to avoid care and jeopardise the name, and fame of the orthodontic practice and the practitioner.

Debates about the "ideal" timing of orthodontic treatment have focused on issues of biologic development and readiness. In this article we examine psychologic issues that should be considered in the decision to initiate orthodontics in the younger child or to wait until adolescence or later. Psychologic development during the preadolescent and adolescent stages may influence the child's motive for, understanding of, and adherence to treatment regimens.

Conclusion

The oral-facial region is usually an area of significant concern for the individual because it draws the most attention from other people in interpersonal interactions and is the primary source of vocal, physical, and emotional communication. As a result, patients who seek orthodontic treatment are concerned with improving their appearance and social acceptance, often more than they are with improving their oral function or health. Enhancing these aspects of quality of life is an important motive for undergoing orthodontic treatment. Regardless of age, patients' and their parents' or caregivers' expectations about improvements in oral function, esthetics, social acceptance, and body image are important for both general dentists and orthodontists to consider when advising patients about these procedures and during the treatment process. This review of research on the impact of conventional and surgical orthodontics on quality of life examines the association between oral health-related quality of life and severity and type of malocclusion, as well as the impact of treatment and patient characteristics on quality of life. It is good to emphasise the importance of clinicians' having a clear understanding, before initiating treatment, of their

patients' quality of life and their expectations about improvements in specific domains of quality of life [19].

The unwillingness of male adolescent patients for seeking orthodontic treatment is studied and the reasons are discussed. This will help in educating them on the long term effects of malocclusion and to convince them for opting to go ahead with orthodontic treatment. Despite having good knowledge on orthodontic treatment, patient's attitude and practice towards orthodontic treatment is mostly moderate. It is important for practicing orthodontists to inform patients about the retainers, appliance maintenance and build inter-personal rapport with the patients. The practitioners shall improve the patient attitude by shortening the waiting time of patients at waiting room, adequately spend time on procedure and charge the treatment cost more reasonably [20].

Abstract

Introduction: Most of the patients clean their dentures only once a day. But according to ideal practices the complete dentures should be cleaned regularly at least twice a day to prevent ulcers, periodontal diseases and various lesions in the oral cavity. Like natural teeth dentures also should be cleaned with a brush or with denture cleaners. This must be done regularly to prevent food accumulation and plaque formation. The most common outcome of improper cleaning of the dentures may lead to a condition called denture stomatitis which is the inflammation of the mouth due to poor oral hygiene. Hence, it is necessary to clean the dentures properly to avoid the above mentioned problems.

Materials and methods: The study was conducted with 50 patients of age groups ranging from 40 to 65 years. A questionnaire was prepared and the information was collected based on details such as age, gender, duration of denture wearing, frequency of denture cleansing, the materials used to clean the dentures and nocturnal denture wearing habits. The purpose of the study was explained to the patients and their consent along with their signature and was recorded on the questionnaire.The data was later tabulated and statistical analysis was done using SPSS software and the results were given.

Result : The present study reveals that most of the patients were aware about importance of denture cleansing and materials used to clean the dentures. They were also aware about the technique to clean dentures and also about the nocturnal use of dentures and adverse effects of not maintaining their dentures properly.

Conclusion : Based on the study, the denture hygiene of patients has significantly improved with patients brushing their dentures twice a day or sometimes thrice a day with cleansing liquid and tablets. Still there are a few patients who slept with their dentures at night which should be avoided. Thus dentists should take the responsibility of providing post placement denture hygiene instructions and also to motivate the patients.

Key Words *Dentures, Frequency, Cleansers, Elderly*

Introduction

Replacement of missing teeth is successful only when patients are motivated and aware of correct prosthesis use and hygiene. The quality of the denture, occlusion, denture age, and hygiene are important factors to be considered 1.. The most common lesions include denture stomatitis, angular chelitis, traumatic ulcers, denture irritation hyperplasia or epulis fissaratum, flabby ridges and can even result in oral carcinomas 2.. These lesions are acute or chronic reactions to plaque or a reaction to constituents of the acrylic base, or a mechanical denture injury.Denture stomatitis is an inflammation of the oral mucous membrane involving the palate mucosa when it is completely or partially covered by denture 3. .Food particles may get lodged between the denture and gingiva or the palate and allows the growth of Candida species which may cause denture stomatitis 4.. Denture stomatitis may also be caused due to wearing dentures at night, smoking, age of the denture and poor oral hygiene 5, 6.. Hence once an edentulous patient is fitted with a complete denture, the most important phase of the treatment will be proper denture maintenance. Tooth loss in any adult population is common as the age advances because the factors that leads to the loss of teeth – dental caries, loss of periodontal support, a history of dentoalveolar trauma, a history of dental care – are additive over time. For this reason, the rates of complete tooth loss are customarily the highest in the oldest age groups mostly after the 5^{th} decade of life 7..

Loss of teeth in elderly people is very common and it may be due to caries, periodontal infections, trauma or bone resorption. Hence in such cases, the only possible treatment will be the fabrication of a complete denture. This treatment will be successful only if the patients are fully aware of denture maintenance and hygiene 8, 4.. Proper care of the dentures and the surrounding oral mucosa is mandatory to avoid certain complications. Poor denture hygiene can lead to various complications like denture stomatitis, angular chelitis, traumatic ulcers and oral carcinomas 9, 15..

For elderly people, proper care of mucosal tissues and care of the dentures are mandatory to maintain the overall health. In addition, there may be greater social consequences of mouth malodour due to unclean oral prosthesis for someone whose dietary intake is strongly linked to socialisation, such as an older person who attends a senior activities

centre for meals. Dentures which are not cleansed adequately cause or contribute to oral mucosal lesions, impairment in eating, and thus will have a more profound effect on a fragile elder than on a younger, healthier person 10, 11..

Various methods of denture cleansing are available such as mechanical and chemical methods. The most common and widely used is the mechanical method of denture cleansing which involves using a toothbrush. There are brushes specifically designed and sold commercially for this purpose15.. Chemical denture cleansers are immersion type cleansers which are sold in powder and tablet forms. They can be broadly divided into alkaline peroxides, alkaline hypochlorite, acids (hydrochloric acid and phosphoric acid), and disinfectants (chlorhexidine gluconate and salicylate) 15.. Combination of mechanical method and chemical method is the most recommended as well as effective and safe method to clean dentures, for persistent accumulations and stains.

Patients should be instructed to rinse their dentures and their mouths after meals whenever possible. The mucosal surfaces of the residual ridges and the dorsal surface of tongue also should be brushed daily with a soft brush; denture cleansers may also be used. However, it has been observed that the majority of denture wearers do not pay necessary attention to the cleanliness. This may be due to decreasing manual abilities due to advanced age 12, 13, and 14.. Thus it is the primary duty of the dentist to create awareness about denture hygiene and also about the products available to clean the dentures. So, this cross-sectional study aimed to investigate the denture cleansing habits among denture wearers.

Materials and Methods

The study was conducted with 50 patients of age groups ranging from 40 to 65 years. A questionnaire was prepared and the information was collected based on details such as age, gender, duration of denture wearing, frequency of denture cleansing, the materials used to clean the dentures and nocturnal denture wearing habits. The purpose of the study was explained to the patients and their consent along with their signature and was recorded on the questionnaire.The data was later tabulated and statistical analysis was done using SPSS software and the results were given.

Statistical Analysis

The tabulated data were analysed using SPSS version 17.0. Descriptive statistics were obtained and the frequency distribution along with the cumulative percentage was also calculated. The analysed data was interpreted.

Results

Out of 50 patients who were interviewed, 50% (25) were males and 50% (25) were females and 46% of patients have been wearing their dentures for 1 to 3 years, 40% of patient'shave been wearing their dentures for 5 to 10 years and 14% have been wearing dentures for more than 10 years. This data is evident in table -1.

Table-1 showing Duration of denture wearing

Duration of denture wearing	Frequency	Percent	Valid Percent	Cumulative Percent
1-3	23	46.0	46.0	46.0
5-10	20	40.0	40.0	86.0
>10	7	14.0	14.0	100.0
Total	50	100.0	100.0	

Out of the 50 patients38 patients (76%) were comfortable with their dentures while 12 patients (24%) were not comfortable with the dentures and experienced some problems.
The data is shown in table -2.

Table-2 showing Comfort level of patients

Comfort level	Frequency	Percent	Valid Percent	Cumulative Percent
Yes	38	76.0	76.0	76.0
No	12	24.0	24.0	100.0
Total	50	100.0	100.0	

The next topic which was asked was about the method the patients used to clean their dentures. It was concluded that 46% of patients used tooth brush to clean their dentures,

while 40% of patients used their hand to clean the dentures and the remaining 7% used materials like cotton or cloth to wipe their dentures. The data is shown in table-3.

Table -3 showing the cleansing methods used

Methods used for cleaning	Frequency	Percent	Valid Percent	Cumulative Percent
Tooth brush	23	46.0	46.0	46.0
Hand	20	40.0	40.0	86.0
Others	7	14.0	14.0	100.0
Total	50	100.0	100.0	

When the patients were asked about the material they used to clean (table-4) their dentures, it was seen that 46% of patients used their tooth pastes to clean; 28% used cleansing powder and 26% used cleansing liquid to clean their dentures.

Table-4 showing material used to clean

Materials used to clean	Frequency	Percent	Valid Percent	Cumulative Percent
Tooth paste	23	46.0	46.0	46.0
Cleansing powder	14	28.0	28.0	74.0
Cleansing tablet	13	26.0	26.0	100.0
Total	50	100.0	100.0	

The patients were also asked about their awareness of the cleansing products available in the market. To this 68% of patients gave a positive reply and 32% gave a negative answer.

Table-5 showing the awareness towards cleansing products

Awareness	Frequency	Percent	Valid Percent	Cumulative Percent
Yes	34	68.0	68.0	68.0
No	16	32.0	32.0	100.0
Total	50	100.0	100.0	

The most important aspect of this survey was to know the frequency of cleansing. When the patients were questioned regarding this, it was observed that 22% of patients cleaned their dentures only once a day, while 56% of patients cleaned their dentures twice a day.

Cleaning their dentures was associated with the advice of the dentist. Patients who followed their regular dental check up kept their dentures cleaner compared to the others.

Table-6 showing frequency of cleansing

Frequency of cleansing	Frequency	Percent	Valid Percent	Cumulative Percent
Once	11	22.0	22.0	22.0
Twice	28	56.0	56.0	78.0
Others	11	22.0	22.0	100.0
Total	50	100.0	100.0	

The next question that was asked was about the nocturnal denture wearing habits. It was seen that 54% of patients slept with their dentures and 46% of patients removed their dentures during night.

No significant difference was observed between gender and denture hygieneand alsoage and denture hygiene.

Table-7 showing the nocturnal use of dentures

Nocturnal use of dentures	Frequency	Percent	Valid Percent	Cumulative Percent
Yes	27	54.0	54.0	54.0
No	23	46.0	46.0	100.0
Total	50	100.0	100.0	

Discussion

Poor denture hygiene has a negative impact on elderly people and can cause many systemic manifestations and infections. When a denture is placed in the mouth, a coating of glycoprotein develops.This thin pellicle becomes contaminated with food debris and microorganisms. Hence, denture stained by tobacco and medicines results in unpleasant taste and malodour. This favourscandidalgrowth and proliferation in the denture leading to mucosal irritation. Denture care is, therefore, an imperative step to maintain denture quality, aesthetics and longevity to ensure good oral health status.Thus it is essential to maintain proper denture hygiene regularly 15..

In this study it is seen that 46% of patients have been wearing dentures for the past 1 to 3 years only whereas 40% of them have been using dentures for 5-10 years and only a small portion of patients are long term denture wearers that is for more than 10 years. It is also observed that 76% of patients were comfortable with their dentures whereas 26% experienced some problem and were not comfortable in using their dentures.

It is also seen that 46% of patients used tooth brush to clean their dentures and 40% used only their hand to clean their dentures and 7% of patients used substances like cotton or cloth to just wipe their dentures without washing them. It is thus seen that these patients have either not received the appropriate information from their dentist or have not been following them as per the instructions given.

When the patients were assessed for their awareness about various denture cleansers available in the market it was observed that 68% of patients were aware about the availability of denture cleansers in the market whereas 32% of patients were totally not aware about such cleaning agents.

The most important aspect of this study was to assess the frequency of denture cleansing and it was seen that 22% of patients cleaned their dentures once a day whereas 56% of patients cleaned their dentures twice a day. Thus it is observed that majority of patients are cleaning and maintaining their dentures properly.

It is also observed that majority of the patients remove their dentures during night. Patients were also additionally aware that nocturnal use of dentures may result in denture stomatitis and other oral mucosal lesions.

It was also observed that gender and denture hygiene were not significantly related. None of the patients were aware of denture brushes and they used ordinary tooth brushes to brush their dentures. Thus it is essential that dentists give all the possible instruction to their patients on how to clean the dentures and also the oral mucosa to maintain a good oral hygiene.

Peracini et al. reported 58.49% of the patients using immersion for cleaning and among the substances used for immersion of the dentures, water was the most frequently used (38.71%) followed by sodium hypochlorite (33.87%). In the study by Baran and Nalça, 42.9% of the patients immersed their dentures in water and only 1.6% immersed them in hypochlorite solution. Hoad-Reddick et al. found that a combination of methods (brushing and soaking) was used more frequently 1..

The primary objective of maintaining the complete denture is to prevent the occurrence of lesions like commissural chelitis, burning mouth syndrome, mouth ulcer, denture irritation hyperplasia, gagging leading to caries and periodontal disease in the oral cavity. In elderly patients, care of the mucosal tissues and the dentures of the edentulous mouth are very important for overall health. The main aim of cleaning the denture is to remove the plaque adhering to the denture which in turn will eliminate the cause of denture stomatitis.Denture cleansers can be used for this purpose. An ideal denture cleanser should be simple to use, should be efficient in removing organic and inorganic matter or plaque from denture surface, have antimicrobial properties and be compatible with all denture base materials 16.. Chemical agents for denture cleansing have advantage of being simple to use, and several investigations have shown their efficacy in reducing biofilm formation in vitro 17-19. and in vivo 20, 21.. Thus it is the duty of every dentist to educate the patient about the importance of denture hygiene and frequency of cleaning the dentures 22..

Conclusion

Based on the study, the denture hygiene of patients has significantly improved with patients brushing their dentures twice a day or sometimes thrice a day with cleansing liquid and tablets. Still there are a few patients who slept with their dentures at night which should be avoided. Thus dentists should take the responsibility of providing post placement denture hygiene instructions and also to motivate the patients.

Abstract

Introduction: Dental radiographs are one of the principal diagnostic methods used in dentistry.The safe and effective use of x-ray equipment is important to the protection of the patient and members of the dental team.The aim of this research is to evaluate the general dental practitioner'sknowledge of dental radiography.

Materials and Methods: The data was collected from 50 general dental practitioners at self convenience using a structured questionnaire consisting of 9 item questionnaire.The sample was selected based on inclusion criteria and exclusion criteria.Inclusion criteria includes undergraduate,postgraduate and chennai dental practitioners. The exclusion criteria includes the students and dental radiograph assistants.In the questionnaire, details were asked about the age of the intraoral radiographic unit, kVp and mA of the equipment, the type of timer on the machine and about the geometry of the machine and the geometric technique used for intraoral radiography.Furthermore, the questionnaire contained questions about the type of intraoral detectors that were used and whether the dentists were also using panoramic machines and, if so, which type of detector they had. Among the possible answers, one option was ''no idea''.The data thus obtained was subjected to statistical evaluation.

Result: 80%(40 dentist)of the equipment used in South chennai dentist was reported to operate between 60 and 70 kVp. ,whereas 20%(10 dentist) claimed to be working at a tube voltage of 50 kVp.

Conclusion: The results of this study showed that the knowledge of dentist in South Chennai regarding dentomaxillofacial radiology is excellent.The level of awareness of practitioners regarding radiation hazards and safety was found to be acceptable.

Key Words: *general practitioners,knowledge, radiology, radiation protection,exposure.*

Introduction

As a dental professional, the utilization of radiograph for finding and further treatment is significantly more regular than different fields of medicine.It is accounted for that around 45% of dental patients require radiographs for determination. (1)Dental radiographs is one of the essential demonstrative techniques utilized as a part of dentistry.Intra oral and extra oral radiographs are two sorts of radiographs available.The sheltered and powerful utilization of x-beam hardware is imperative to the assurance of the patient and individuals from the dental team.Its assumes a critical part in the identification of oral disease.(2)Exposure to such radiation is related with an expanded hazard in the long haul of threatening sickness in those persons.Furthermore, it is accepted that the likelihood of event of these antagonistic impacts is straightforwardly corresponding to the level of presentation, with no measurements threshold.The dangers related with the vital introduction to ionizing radiation might be generous, and must be limited through careful adherence to great practice.(3)

Specialized advances in radiological equipment significantly affect lessening of radiation dosages to patients during intra oral and extra oral radiographs. During extra oral radiography, the utilization of uncommon earth escalating screens has diminished the radiation presentation significantly.(1,4,5)Although the quantity of radiographs taken every day in essential dental care is over the top, the most serious hazard emerges when there is proof of poor picture quality or non-diagnostic images inferable from poor specialized information and the insufficient handling of films (6-10). It has been evaluated that the disposal of non-beneficial examinations could prompt a 30% lessening in the aggregate populace measurements, got from medical radiology.(11) Dental hygienists assume an imperative part in handling and they should accept the accountability for poor preparing rehearses, the majority of which concern not supplanting preparing arrangements as oftentimes as required, overdeveloping and overfixing. Accordingly, numerous dental

practitioners tend to build the presentation time to make up for the disgraceful preparing, therefore expanding the radiation measurements to patients. (12)

For dispensing with unnecessary X-beam examinations, each expert who works X-beams ought to be appropriately prepared as per the Ionizing Radiation Medical Exposure Regulations 2000.(13) We live in an ocean of radiations. We are constantly exposed to naturally occurring ionizing radiation i.e.,background radiation and furthermore presented to ionizing radiation from manmade sources, for the most part through medical procedures.On an average, doses from a diagnostic X-ray are much lesser, in dose effective terms, than the natural background radiation.Radiation has turned into a part of present day living, achieving each section of our general public. The essential hazard from dental radiography is radiation actuated malignancy. The writing on conceivable destructive impacts of expert analytic presentation for dental specialists isn't steady. The hazard required with dental radiography is surely little in correlation with numerous different dangers that are a typical piece of regular daily existence. In any case, no premise exists to accept that it is zero. Likewise, the biologic impacts of ionizing radiation ingested during dental radiography are questionable. The radiographic examination utilized as a part of all fields of medicinal administrations and adds to the advancement of the well being, both separately and broadly. Radiographic examination has a basic impact of dental practice. Certain measure of radiation is unavoidably conveyed to patients, it ought to be as low as reasonably achievable (ALARA). International Commission for Radiation Protection (ICRP) is the administrative body which sets down standards for radiation security at the universal level. In India, it is the Atomic Energy Regulatory Board (AERB) which gives the standards to radiation assurance.

AERB prescribes standards for reasonable dosages of radiation from X-beam tubes, the protecting required for the dividers of a X-beam tube room, the lead equal protecting attire to be worn by radiation specialists and sets down safe measurements limits for radiation laborers and for the overall population.Before undertaking any radiological examination, it is important that the provider comprehends the potential dangers and the advantages of radiation. The dangers can be stochastic (of which likelihood increments with dosage) and deterministic (of which severe increments with measurement).Cancer induction and hereditary effects are stochastic impacts and blood dyscrasias,cataracts and imparired fertility are cases of deterministic effects.Biological effects of ionizing radiation are gathered into stochastic and deterministic effects. Over a specific decided dosage of radiation organic harm

starts to show up, this is called as deterministic impact. Stochastic impact is that in which there is no specific dosage level above which natural change happens in the body.

Ionizing radiation causes both the impacts relying upon radiation doses and body's reaction to these radiations. Dental practitioners and in addition patients are more inclined to the danger of stochastic effects because of its lack of a dose threshold limit. The positive parts of diagnosis of disease and detection of disease should be considered while assessing the risk of impacts of radiation. It is essential for dental practitioner to refresh their insight about new patterns in analytic strategies, protective measures, etc.This can be accomplished by methods for proceeding with training, continuing education, journals,workshops, and other media.In India, diagnostic radiation facilities are administered by Atomic Energy Regulatory Board (AERB).The role of the AERB is to guarantee that utilization of ionizing radiation and atomic vitality in India does not make undue hazard the well being of individuals and the environment.It is required to enlist all diagnostic radiation facilities in e-Licensing of Radiation Application (eLORA) system of AERB. From December first, 2013, it is mandatory for dental specialists and dental institutions to enroll in eLORA and get a license to operate dental X-ray units, panaromic machines, and cone bean computed tomography. It is additionally essential for manufacturers of X-ray machines to get a license available to be purchased in India by AERB.

The current radiation protection standards are based on 3 principles : Justification of a practice, optimization and dose limitation.In spite of the fact that the radiation dosage levels in dental practice are generally low, one ought to think about the combined impact of repeated exposures. There ought to be a making progress toward radiation assurance measures in the private dental offices.(14)There is an association between knowledge and the use of low-dose techniques and attitudes towards risks.(15)A dental professional should always be prepared to improve his or her knowledge through continuous education, it is a well-known fact that this is more likely to occur if the continued education is mandatory for all dental professionals, for whatever local or federal reasons.(16)

The reason for performing this study was to alert the dental professional societies that more attention should be paid to radiation protection in dentistry in our country. The aim of this research is to evaluate the general dental practitioners knowledge of dental radiography .

Materials and Method

Data was collected from 50 general dental practitioners using a structured questionnaire consisting of 9 item questionnaire.The sample was selected based on certain inclusion and exclusion criteria.

Inclusion Criteria

1. Undergraduate
2. Postgraduate
3. Chennai dental practitioners

Exclusion Criteria

1.Students

2.Dental radiograph assistants

In the questionnaire, details were asked about the age of the intraoral radiographic unit, kVp and mAofthe equipment, the type of timer on the machine and, about the geometry of the machine and the geometric technique used for intraoral radiography.Furthermore, the questionnaire contained questions about the type of intraoral detectors that were used and whether the dentists were also using panoramic machines and, if so, which type of detector they had. Among the possible answers, one option was ‘‘no idea’’.The data thus obtained was subjected to statistical evaluation.

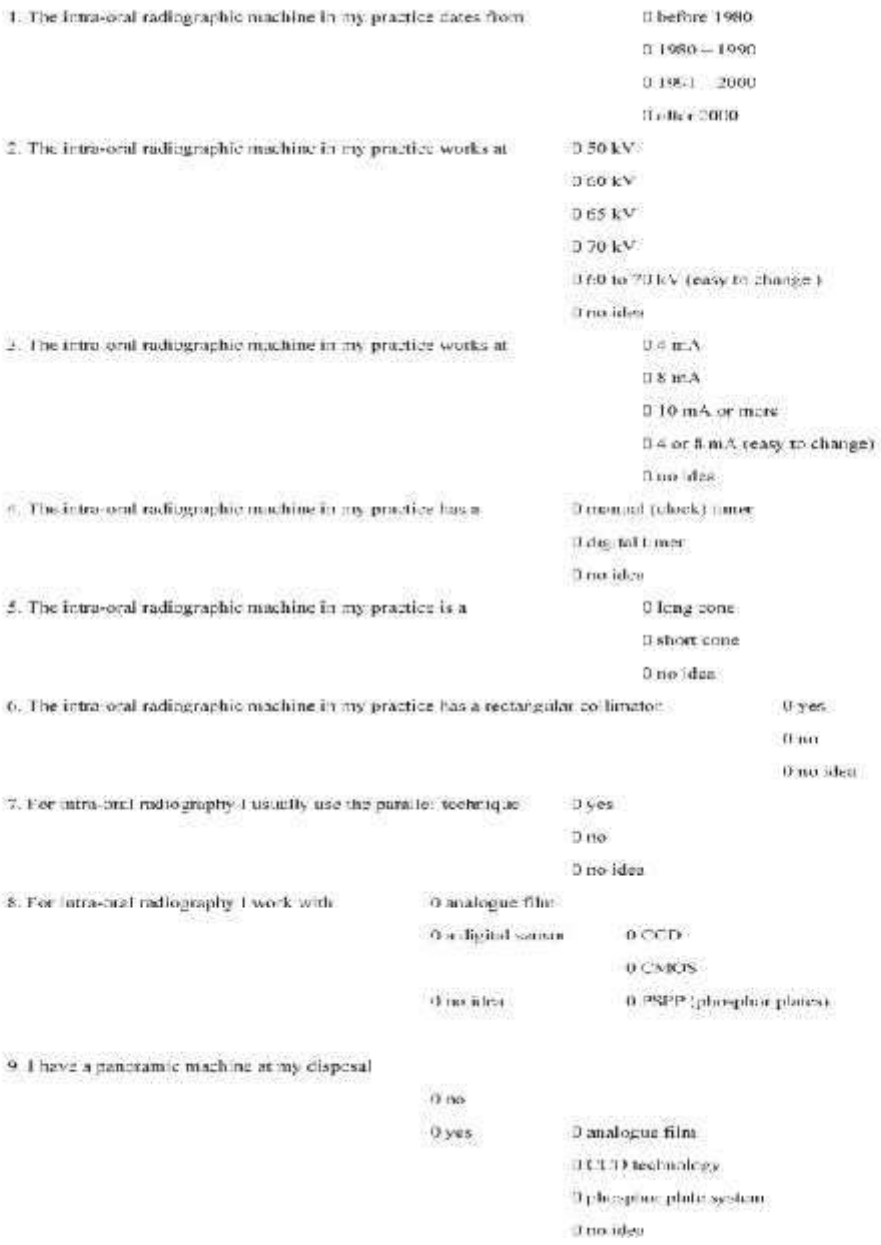

Figure 1: Questionnaire

Result

Table1: Responses from the study subjects to the questionnaire in percentage(%)

Intra - Oral Radiographic Machine	Condition	Percentage
Practice dates from	After 2000	100%
Works at (Kv)	70Kv	20%
Works at (Kv)	60Kv to 70Kv	80%
Works at (mA)	4 or 8mA	92%
Works at (mA)	No Idea	8%
Timer	Digital Timer	100%
Shape	Long Cone	6%
Shape	Short Cone	94%
Rectangular Collimator	Yes	20%
Rectangular Collimator	No	80%
Parallel Technique	Yes	18%
Parallel Technique	No	82%
Works with	Digital Censor - CCD	24%
Works with	Digital Censor - PSPP	76%
Panaromic Machine Disposal	No	10%
Panaromic Machine Disposal	Yes - Analogue Film	80%
Panaromic Machine Disposal	Yes - CCD Technology	10%

Discussion

As mentioned above the data was collected from 50 general dental practitioners using a structured questionnaire consisting of 9 item questionnaire.The sample was selected based on certain inclusion criteria and exclusion criteria.Inclusion criteria which includes the Chennai dental practitioners,undergraduates,postgraduates and Exclusion criteria includes Students,dental radiograph assistants.Regarding the age of the intraoral radiographic equipment used by the questioned population of chennai dentists, it was found that almost 100%(50 dentist) were using radiographic machines for intraoral radiography equipment that was after 2000.

As the answers about the tube voltage of the intraoral equipment was mild difference the answers were condensed into two groups. Therefore, tube voltage ranging from 60 to 70 kV was considered as one category. 80%(40 dentist)of the equipment used in South chennai dentist was reported to operate between 60 and 70 kVp. ,whereas 20%(10 dentist) claimed to be working at a tube voltage of 50 kVp.

The majority of the South Chennai dentists were using 4 or 8mA(easy to change) equipment for intraoral radiographs ; 8%(4 dentist) claimed they not knew what they were working .

100% (50 dentist)claimed to be working with a digital exposure timer, whereas none said they were still working with a manual (clock-like) exposure timer.

It was found that 94% (47 dentist)said that they were working with a short cone geometry, whereas 6% (3 dentist)claimed to be working with a long cone geometry.

20% (10 dentist)said they were using a rectangular collimator.80%(40 dentist) responded that they were using circular collimatior.

18%(9 dentist)claimed to be working with the parallel technique, whereas 82%(41dentist) said they were working with the bisecting angle technique.

76%(38 dentist)of the dentists in South Chennai were still using PSPP sensor films for intraoral radiography. 24%(12 dentist) had digitized to intraoral sensors as charge coupled device (CCD).

About 10% (5 dentist)of the dentists has no intention idea what sensor they using.10%(5 dentist) of South Chennai dentist don't not posses a dental Panaromic machine. Others 80% use analogue films and 10% (5 dentist)use CCD technology.

A dental professional should know his or her equipment and it is expected to know the main guidelines on radiation protection.The overall conclusion of this study,is that a great deal of work done to ameliorate the quality of radiographs and the knowledge and attitude of general dental practitioners regarding dentomaxillofacial radiology.(2) This is a task for dentomaxillofacial radiology specialists, who will have to concentrate in the first place on undergraduate teaching and then on postgraduate teaching. The latter is not less important than the first as the working dentist population needs to change their attitude regarding radiation protection and dentomaxillofacial radiology general knowledge. (3)This has also been stressed in other surveys. From the results ,it is evident that continued education in dentomaxillofacial radiology is essential, especially when considering a change from analogue to digital radiology.(4)That 92%(46 dentist)of the dentists in the present survey claimed to be working with a short cone radiographic machine is probably biased by the fact that they are not aware of the difference between a short cone and a short spacer cone, which is also called a beam indicating device or position indicating device.(17)It can be assumed that dentists owning a machine with a short spacer cone, because the manufacturer positioned the focus near the rear end of the machine, gave the wrong answer. Therefore this result should be interpreted with care. The opposite for long cone could also be the case, of course.

(18)The results are, therefore , excellent.This could mean, for instance,increased in the number of hours of under and /or postgraduate education. If this can be decided by the local authorities and enforced at university level, it had a chance of succeeding. However, at

present, every university has its own curriculum.And as known from other studies, it is not always easy to change curricula and convince faculty staff colleagues of this issue.(19)

Regarding the knowledge of Chennai's general dental practitioners, there are various reasons for the results of this questionnaire being excellent . Perhaps the quality and quantity of the undergraduate education is good.However, it is the personal impression that, for many years, dentomaxillofacial radiology has been taught at every university in the country by medical radiologists or general dentists with specific dentomaxillofacial radiology training.The major problem with the undergraduate education is the number of hours that should be dedicated to dental radiology.The age of the dentists was not assessed and also the university where they had studied. Age was not considered an important question in this study, as the age of a dentist does not always reflect that person's knowledge of dental radiology.Furthermore, it is known that not every young dentist starts with new equipment and, vice versa, that not every "older" dentist is working with old equipment. Therefore, the age of the intraoral radiographic equipment was considered more important and more relevant as a question.(20)The level of knowledge and the attitude of dentists regarding radiation safety will have a direct impact on patient exposure to radiation (Shahab et al. 2012). Many studies have been done to determine the knowledge and attitude of dentists regarding radiation safety.

Shahab et al reported a study pertaining to radiation safety to assess the knowledge of dentists with regard to basic information in relation to radiation protection and methods of reducing the radiation dose to the patient. The majority of dentists did not employ appropriate procedures to decrease exposure to unwanted radiation.(21)

Mutyabule and Whaites conducted a study to assess radiation protection measures in dental practices in Uganda. It was found that operators lacked sufficient knowledge regarding radiation safety protection measures.(22)

Aps assessed dentists' knowledge regarding radiation safety. The dentists were asked about various methods of dose reduction to the patients. The results of the study highlighted the need to increase knowledge of dental practitioners regarding radiation safety and methods of dose reduction.(23)

Lee and Ludlow assessed the attitude of dentists regarding radiation safety. The dentists were asked about primary knowledge of radiation safety and the method of reducing the dose to the patient such as speed of the film, collimation of the X-ray tube and the regular use of

shielding. Results of the study confirmed that there is a demand to reinforce the dentist's working knowledge about the issue of radiation safety.

Math et al assessed the understanding of dentists regarding radiation safety standards with regards to the X-ray machine, collimation of the tube, regular use of a film holder, shielding and the position of the operator during radiation exposure. The result of this study also highlights the need to increase the practitioner's awareness and attitude regarding radiation hazard and use of appropriate methods to reduce the radiation dose.(24)

Jacobs et alconducted a study regarding the perceptions of the dentists of radiation protection. The results of this study concluded that there was a need to apply strict guidelines toward radiation safety.(25)

Majority of the practitioners still followed the position and distance rule, few were found to be using lead barriers while mere used lead aprons and some using a combination of various safety techniques. Distance in radiation protection refers to distance from the source and the individual. As the distance increases, radiation exposure reduces. Moreover, shieldingincludes both protective barriers such as lead shield and personnel protective measures such as lead apron. Ninety-eight percent reduction in scattered radiation and attenuate dose to 0.04 µR can be achieved using lead aprons.Patient should wear thyroid collar during radiation exposure as it reduces attenuation of scattered radiation to 92%(46 dentist).Proper shielding from radiation and by increasing the distance from source protect radiographer as well as patient for unnecessary exposure to radiation. According to position distance rule, radiographer position should be at least 6 feet from the source at an angle of 90 to 135° to the central ray of X-ray beam.

Conclusion

The results of this study showed that the knowledge of dentist in South Chennai regarding dentomaxillofacial radiology is excellent.This emphasizes that there is better under and postgraduate education in dentomaxillofacial radiology in Chennai. The present report is therefore an important statement for the dental professional society.The level of awareness of practitioners regarding radiation hazards and safety was found to be acceptable. However, implementation of their knowledge with respect to patient and personnel safety was found wanting. Insisting that they follow the protocols and take necessary safety measures by means of continuing medical education programs, pamphlets, articles, and workshops is strongly recommended.From the time of its discovery, X-rays have played a vital role in the field of

medical and dental science. Ranging from diagnostic to therapeutic applications, the use of X-rays is manifold. Probably, the most widespread application is in the field of dentistry from the simple diagnosis of incipient caries, multiple fractures to aiding in more complex procedures such as precision implant planning. The modalities at the disposal of dentists range from intraoral radiography to cone beam computed tomography. During the course of their training, all health-care personnel are trained regarding radiation hazards and requisite safety measures. However, the sincerity with which the matter is considered needs to be assessed from time to time. In the present study, we attempt to evaluate the awarenessand validate the knowledge of radiograpy among general dental practitioners in Chennai,India.Protection of one's self and patient from all kinds of health hazards is the hallmark of concerned doctors. The AERB recommendations should reach out through the dentists' platform (e.g., IDA) to the dental practitioner. Better "safe than sorry" remains no more a virtue but a fundamental necessity.

Abstract

Introduction: The aim of this study is to evaluate knowledge and attitude about ICDAS caries detection among conservative and public health dentistry staff among different colleges in Chennai.To determine the knowledge about ICDAS caries detection among staff of conservative and public health dentistry.

Material and Method: A questionnaire survey was conducted among 50 conservative and public health dentist. The results were evaluated and presented. The international caries detection assessment system (ICDAS) present a new technique for the measurement of dental caries developed from the systematic reviews of literature on the clinical caries detection system and other sources.

Result: To know the knowledge and attitude of ICDAS caries among conservative and public health dentistry staffs.

Conclusion: The ICDAS of future depends on the acceptance of the concepts of integration and utility within a caries detection and assessment system. ICDAS is a valuable method of teaching caries detection and its learning program significantly improves their caries diagnostic skills.

Key Words*: ICDAS, Caries, Enamel, Dentin, Fluorosis.*

Introduction

The International Caries Detection and Assessment System (ICDAS) presents a new technique for the measurement of dental caries developed from the systematic reviews of literature on the clinical caries detection system and other sources [1,2]. All these reviews found that the new caries detection criteria measured different stages of the caries process.The new emphasis on caries measurement and management may indicate that the dental community worldwide has started to recognize that we need new approaches in caries detection, assessment, and management [3]. The development of new technologies and applications has the potential to supplement clinical caries detection, but these assessments will have to be clinically meaningful by providing measurements over and above the rattle of the arrested initial and subclinical lesions [4]. The aim of this study is to evaluate the knowledge and attitude about ICDAS caries detection among conservative and public health dentist.Dental caries is a complex multifactorial disease of the calcified tissues of the teeth, caused by the following factors such as host, agent, substrate and time as demonstrated by the Keyes circle. Detecting carious lesion at the earliest possible stage of its development is definitely helpful in appropriate treatment planning for the same. The ICDAS was developed to bring forward the current understanding of the process of initiation, progression of dental caries to the field of epidemiological and clinical research. This system allows us to record the severity and incidence of the caries in its continuum. In 2002 ICDAS I was developed and was later modified to ICDAS II in 2005. The ICDAS I and II criteria incorporate concepts from the research conducted by Ekstrand et al (1995, 1997) and other caries detection systems described in the systematic review conducted by Ismail et al (2004).

ICDAS

The ICDAS activities have been carried out under the supervision of and on behalf of an unfunded,informal,and an adhoc and voluntary committee, which was assembled in an attempt to advance some of the key recommendations in the area of caries detection and assessment criteria. The principles of the ICDAS committee are: integration, scientific validation, and utility of the criteria in different research and practice settings.Dental caries is a dynamic process with cycles of demineralization followed by remineralization. It is hard to categorize a complex disease like dental caries into a scale because the process is continuous

and can be measured.The ICDAS measures surface changes and potential histological depth of the carious lesions by relying on surface characteristics. The primary requirement for applying the ICDAS system is the examination of clean and dry teeth. The ICDAS examination was visually aided by ball-ended explorer that is used to remove any remaining plaque and debris and to check for surface contour, minor cavitation or sealants. It is highly advisable that the teeth are cleaned with a toothbrush or a prophylaxis head/cup before the clinical examination. The use of sharp explorer is not necessary because it does not add to the accuracy of the detection and it may damage the enamel surface covering the early carious lesions[5]. To improve oral health of the populations, World Health Organization has set the promotion of self care of as one of the goals for the year 2020. Recommended oral self care (ROSC) includes tooth brushing more than once a day, lesser consumption of sugar containing snacks once daily or rarely and regular use of fluoride containing tooth paste. Studies have shown there is an association between increased knowledge regarding oral hygiene and better oral health. Those who have assimilated the knowledge and feel a sense of personal control over their oral health are more likely to adopt self-care practices. The study evaluated the oral health-related knowledge, attitudes and practices of law students belonging to Saveetha university. Health is a universal human need. It has been established that optimal health cannot be attained independent of oral health.(6)Developing such knowledge plays a key role in improving the oral health. The young college students play a vital role in health promotion and preventive information dissemination among the family and their society. It is therefore important that their oral health knowledge is good.(7,8)

ICDAS Codes

The ICDAS detection codes for coronal caries range from 0 to 6 depending on the severity of the lesion.

Code 0: Sound Tooth Surface with Restoration or Sealant

A sound tooth surface adjacent to a restoration/sealant margin, there should be no evidence of caries. Surfaces with marginal defects less than 0.5 mm in width, developmental defects, and extrinsic or intrinsic stains will be recorded as sound. Stained margins consistent with

noncarious and which do not exhibit signs consistent with demineralization should be scored as sound.

Code 1: First Visual Change in Enamel

When seen wet there is no evidence of any change in color attributable to carious activity, but after prolonged air drying an opacity or discoloration consistent with demineralization is visible that is not consistent with the clinical appearance of sound enamel.

Code 2: Distinct Visual Change in Enamel/Dentin Adjacent to a Restoration/Sealant Margin

If the restoration margin is placed on enamel, the tooth must be viewed wet. When wet, there is an opacity consistent with demineralization or discoloration that is not consistent with the clinical appearance of sound enamel and if the restoration margin is placed on dentin, discoloration that is not consistent with the clinical appearance of sound dentin or Cementum is code 2.

Code 3: Carious Defects of < 0.5 mm with the Signs of code 2

Cavitation at the margin of the restoration/sealant less than 0.5 mm, in addition to either an opacity or discoloration consistent with demineralization that is not consistent with the clinical appearance of sound enamel or with a shadow of discolored dentin.

Code 4: Marginal Caries in Enamel/Dentin/Cementum Adjacent to Restoration/Sealant with Underlying Dark Shadow from Dentin

The tooth surface may have characteristics of code 2 and has a shadow of discolored dentin which is visible through an apparently intact enamel surface or with localized breakdown in enamel but no visible dentin. This appearance is often seen more easily when the tooth is wet and is a darkening and intrinsic shadow which may be grey, blue, orange or brown in color.

Code 5: Distinct Cavity Adjacent to Restoration/Sealant

Distinct cavity adjacent to restoration/sealant with visible dentin in the interfacial space with signs of caries as described in code 4, in addition to a gap > 0.5 mm in width or in those instances where margins are not visible, there is evidence of discontinuity at the margin of the restoration/ sealant and tooth substance of the dentin as detected by 0.5 mm ball-ended probe run along the restoration/sealant margin.

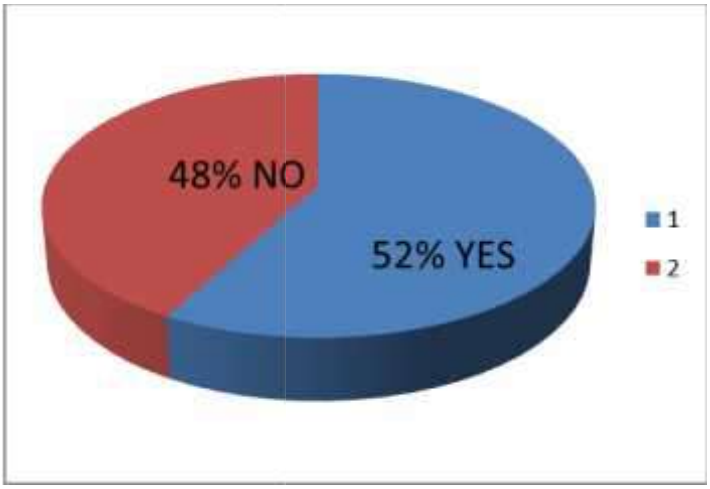
Code 6: Extensive Distinct Cavity with Visible Dentin

Obvious loss of tooth structure, the extensive cavity may be deep or wide and dentin is clearly visible on both the walls and at the base. It is essential to evaluate the clinical application of ICDAS in detection of caries, hence the aim of this study was to analyse the knowledge and attitude about ICDAS caries detection among conservative and public health dentist.

Methodology and Results

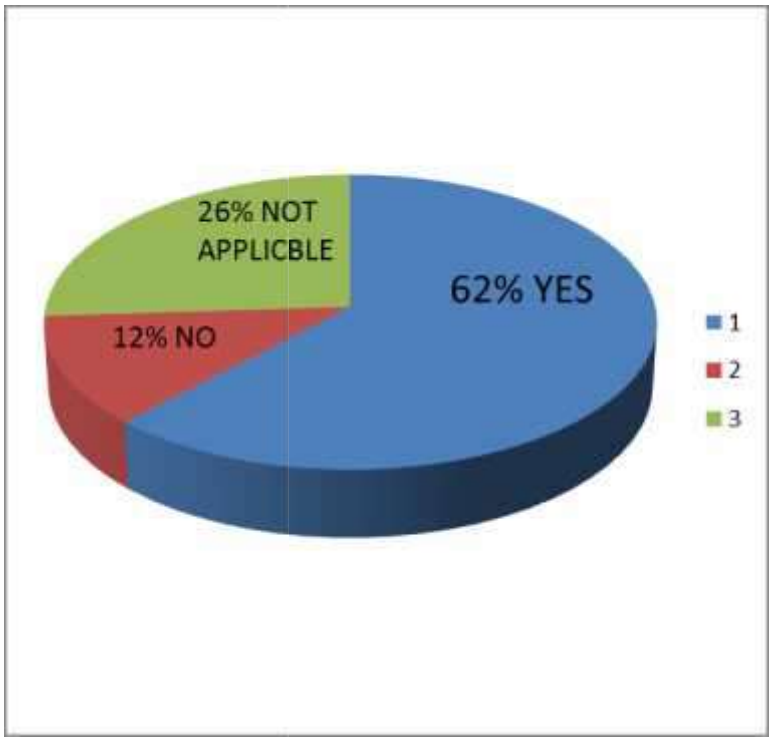
A questionnaire survey was conducted among 50 conservative and public health dentist. The results were evaluated and presented as follows,

1) Have you read articles where ICDAS is used for evaluation of caries?
   29 (58%) people have read articles where ICDAS is used for evaluation, 21(48%) people have never read.



Graph 1: Have you articles of ICDAS.

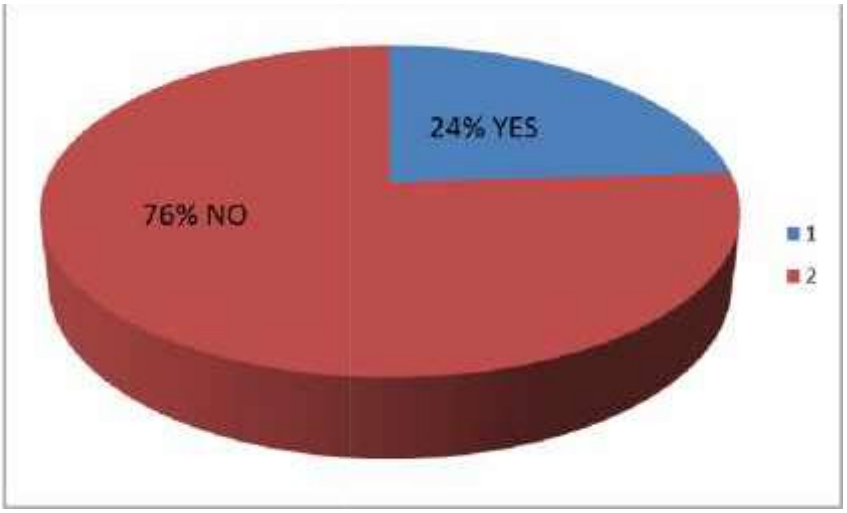
2) If yes, are the reports favourable towards ICDAS in detecting caries over DMFTS?
   31 (62%) people says the reports are favourable, and 6 (12%) says its unfavourable, 13(26%) says its not applicable.



Graph 2: Are the reports favourable towards ICDAS in detecting caries over DMFTS

3) Do you follow ICDAS for caries detection?

12(24%) of dentist says they follow ICDAS for detection of caries, 38(76%) says they don't follow ICDAS for detection of caries.



Graph 3: Do you follow ICDAS for caries detection

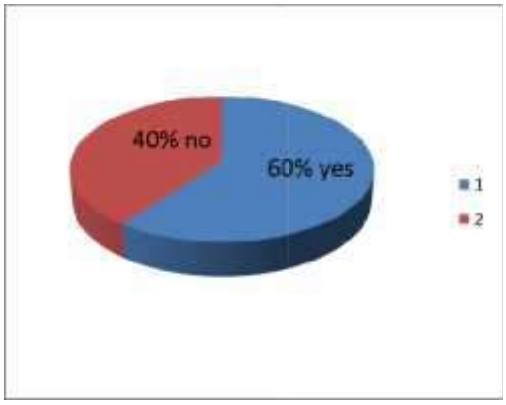
4) Reason, why?

Dentist who don't follow says its complicated, they are unaware of it.

Dentist who follow ICDAS says its very accurate.

5) Is ICDAS method easy to detect the stage of caries?

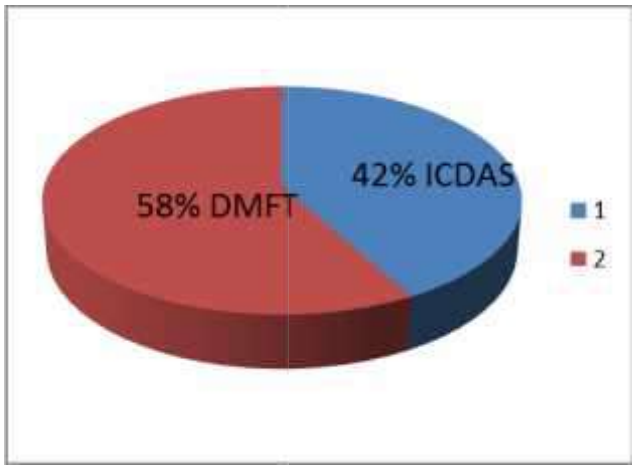
   30 (60%) says yes and 20(40%) says no.



Graph 4:Is ICDAS method easy to detect the stage of caries

6) Which system is very useful in detection of early carious lesion?

   21 (42%) says its DMFT and 29(58%) says its ICDAS



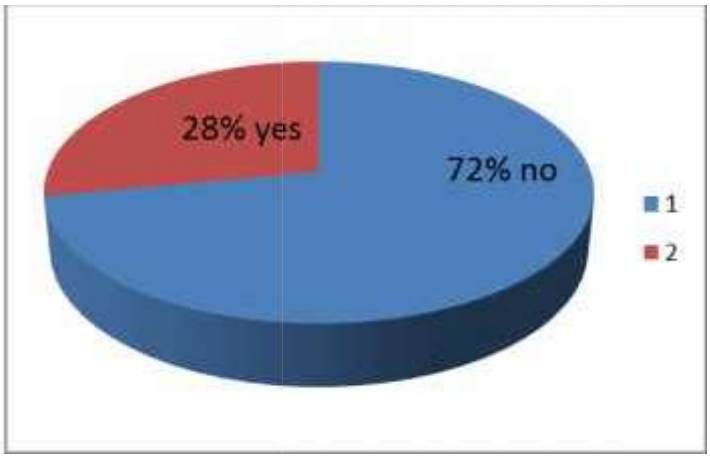
Graph 5:Which system is very useful

7) Which probe should be used to detect caries?

   WHO probe(87%) is used to detect caries.

8) Does DMFT show any details about dental status of caries?

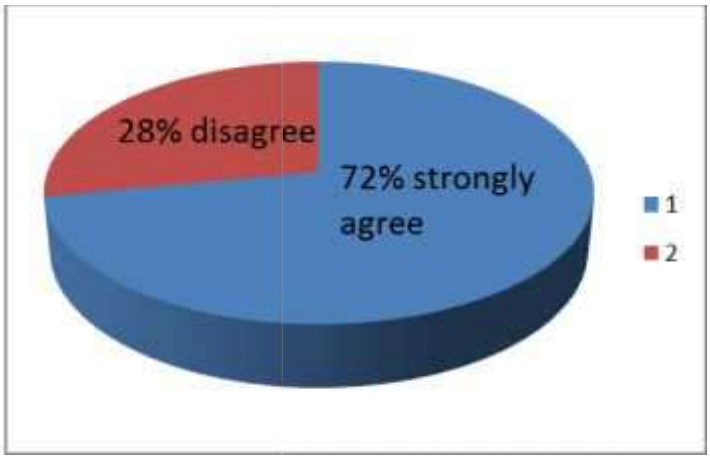
   36(72%) says no , 14(28%) yes



Graph 6: Does DMFT show any details about dental status of caries

9) Identifying the stage of caries influences the treatment plan?

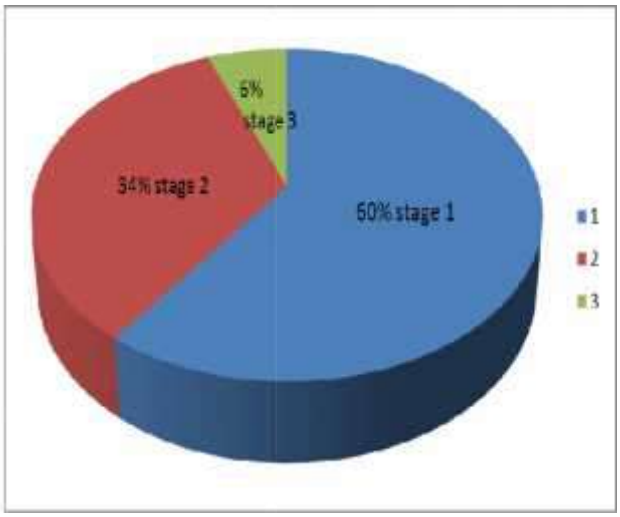
36(72%) dentist strong agree and 14(28%) disagree



Graph 7: Identifying the stage of caries influences the treatment plan

10) First visual change in enamel is an dental term of which stage?

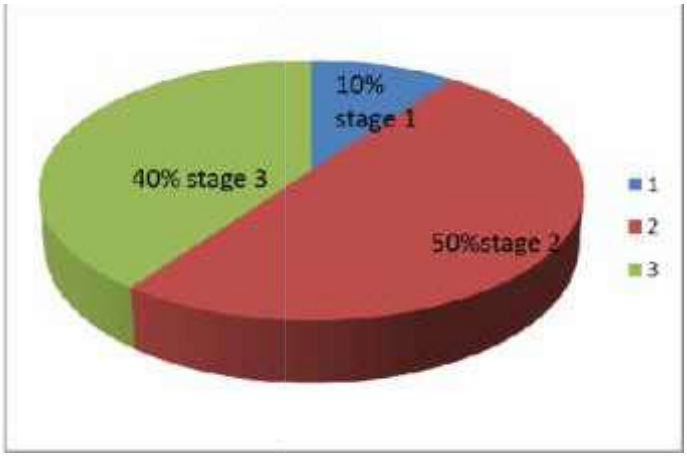
30(60%) of dentist says its stage 1,17(34%) says its stage 2, 3(6%) says its stage 3



Graph 8: First visual change in enamel is an dental term of which stage

11) Distant visual change in enamel is an dental term of which stage?

5(10%) dentist says stage 1, 25(50) says stage2, 20(40%) says stage 3



Graph 9: Distant visual change in enamel is an dental term of which stage

12) Which of the following guidelines are you aware of (tick one or both)

Table 1: Are you aware of following guidelines

S.NO		I AM ONLY AWARE	I HAVE READ
1	Radiographic diagnostic guidelines(ADA)		
2	Systemic fluoride protocol(CDC)		
3	Topical fluoride protocol(ADA)		

4	Guidelines for pit and fissure sealants(ADA)		

34(68%) of dentist are aware of the following guidelines, and 16(32%)have read the articles.

13) Which of the following are necessary to assess caries risk?

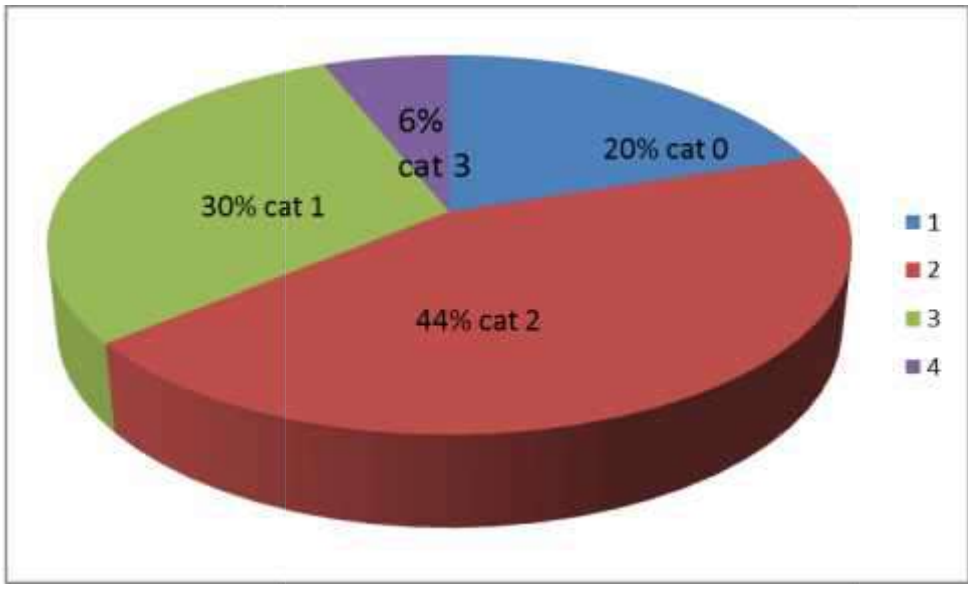
Table 2: Are they following necessary to assess caries risk

S.NO		VERY IMPORTANT	IMPORTANT	LESS IMPORTANT	NO CORRELATION
1	Diet				
2	PH salivary assessment				
3	Saliva buffering capacity				
4	Flow rate of saliva				
5	Socioeconomic status				

Every dentist says diet, PH salivary assessment, saliva buffering capacity, flow rate of saliva, socioeconomic status is very important to assess caries risk.

14) Under which categories fluorosis, enamel hypoplasia and tooth wear come?

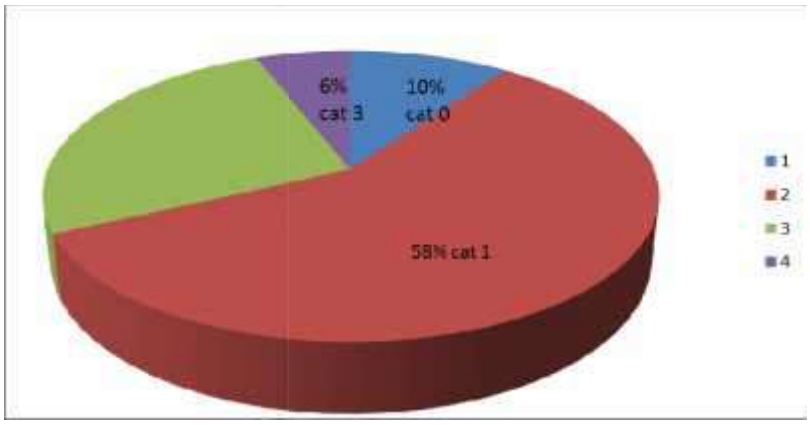
10 (20%) dentist says it comes under category 0,22(44%) says its 1, 15(30%) says its 2,3(6) says its 3.



Graph 10: Under which categories fluorosis, enamel hypoplasia and tooth wear come

15) Pits and fissures comes under which categories of ICDAS?

5(10%) dentist says its comes under category 0, 29(58%) says its 1, 13(26%) says its 2, 3(6%) says its 3.



Graph 11: Pits and fissures comes under which categories of ICDAS

Discussion

According to present study, 29 (58%) people have read articles where ICDAS is used for evaluation, 21(48%) people have never read. 31 (62%) people says the reports are favourable, and 6 (12%) says its unfavourable, 13(26%) says its not applicable. 12(24%) of dentist says they follow ICDAS for detection of caries, 38(76%) says

they don't follow ICDAS for detection of caries. Dentist who don't follow says its complicated, they are unaware of it. Dentist who follow ICDAS says its very accurate. 30 (60%) says yes ICDAS method easy to detect the stage of caries and 20(40%) says no. 21 (42%) says its DMFT is very useful in detection of early carious lesion and 29(58%) says its ICDAS. WHO probe(87%) is used to detect caries. 36(72%) says no DMFT does not show any details about dental status of caries , 14(28%) yes its shows.36(72%) dentist strong agree Identifying the stage of caries influences the treatment plan and 14(28%) disagree. 34(68%) of dentist are aware of the following guidelines(Radiographic diagnostic guidelines(ADA), Systemic fluoride protocol(CDC), Topical fluoride protocol(ADA),Guidelines for pit and fissure sealants(ADA), and 16(32%)have read the articles. Every dentist says diet, PH salivary assessment, saliva buffering capacity, flow rate of saliva, socioeconomic status is very important to assess caries risk.

Dental caries is a dynamic process with cycles of demineralization followed by remineralization. It is hard to categorize a complex disease like dental caries into a scale because the process is continuous and can be measured. The ICDAS is a good tool to identify the nature of caries, the icdas has the sub category (9,10)

Code 0- Pits and fissures; smooth surface (mesial or distal); free smooth surfaces and caries associated with restorations and sealants (CARS) comes under category 0, There should be no evidence of caries.(11) Surfaces with developmental defects such as enamel hyperplasia, fluorosis, tooth wear (attrition, abrasion, and erosion), and extrinsic or intrinsic stains will be recorded as sound First visual change in enamel(code 1): When seen wet there is no evidence of any change in color attributable to carious activity, but after prolonged air drying, a carious opacity or discoloration (white or brown lesion) is visible, which is not consistent with the clinical appearance of sound enamel, or when there is a change of color due to caries it is not consistent with the clinical appearance of sound enamel. Distinct visual change in enamel(12,13) (code 2) : The tooth must be viewed wet. When wet there is a carious opacity (white spot lesion) and/or brown carious discoloration that is wider than the natural fissure/fossa, which is not consistent with the clinical appearance of sound enamel.

Iranzo-Cortezet al in 2017, assess the diagnostic efficacy of the International Caries Detection and Assessment System (ICDAS II) criteria and the DIAGNOdent laser

fluorescence (LF) pen in occlusal caries lesions, using histological sections as the gold standard. It was concluded that both methods are efficacious individually but combining the two is recommended to improve the diagnosis (14). Nogueria et al in 2017, did a study to evaluate, prospectively, the influence of examiner's experience in interpreting and applying the caries detection systems ICDAS (IC) and Nyvad (NY).ICDAS criteria seem to be instinctively understood by students without clinical experience. Nyvad's concepts performed better after two years where the students deepened their theoretical knowledge and experienced clinical practice, collaborating with the identification of activity signs (15).Melger et al in 2016, did a study to describe and compare findings regarding the prevalence and severity of dental caries when using ICDAS and DMFT/dmft in an epidemiological study with children and their mothers. it was observed that DMFT/dmft index would underestimate 60% of non-cavitated lesions in children and 16.6% in adults. The DMFT/dmft underestimated the presence of disease to disregard non-cavitated lesions for the pediatric population evaluated. Whereas ICDAS gives information about the stage or progression of caries(16).Wan baker in 2016, did a study to investigate the accuracy of the Canary System (CS) to detect proximal caries lesions in vitro, and compared it with conventional methods: International Caries Detection and Assessment System (ICDAS) II and bitewing radiography (BW).The CS demonstrated greater accuracy in detecting proximal lesions than ICDAS-II and BW, although without significantly higher specificity (17).Henry et al in 2016, did a study to assess the prevalence of ECC in 0- to 3-year-old children from rural areas of South India, using the ICDAS.The results demonstrate the high prevalence of ECC in this population and the need to consider early diagnosis and specific preventive interventions. For that early diagnosis ICDAS is used (18).Arangannal et al in 2016, did a study to assess the prevalence of dental caries in school children aged between 6-14 years using the International Caries Detection and Assessment System (ICDAS II).The surfaces with early caries lesion (ICDAS code 2) are more common in the surveyed population. Careful monitoring and the preventive program could decrease the risk for dental caries and minimize the need for invasive and painful treatment procedures in the latter part of their life (19).Brun et al in 2016, did a study to evaluate The International Caries Detection and Assessment System (ICDAS) of dental caries. The aim of the present study was to compare the ICDAS scores and radiologically

evaluated caries depths to the histologically evaluated carious lesions in permanent teeth.The present study indicates an acceptable validity of the ICDAS II criteria when applied to permanent teeth. Especially, dentin lesions can be reliably detected. Thus, ICDAS assessment provides the possibility of reducing X-ray exposure for caries detection.

Conclusion

The future of ICDAS depends on the acceptance of the concepts of integration and utility within a caries detection and assessment system. ICDAS is a valuable method of teaching caries detection and its learning program significantly improves their caries diagnostic skills. ICDAS would certainly promote preventative therapies worldwide that encourage the remineralization of noncavitated lesions resulting in inactive lesions and the preservation of tooth structure, function and esthetics and a much decreased DMF all-over. An active collective effort of the dental health care team can make awareness program more effective and can also make people more aware about the importance of dental caries prevention.(20)

Abstract

Introduction: The oral health of children depends on awareness of their parents regarding importance of primary teeth and importance of maintenance of oral heath. Parents have an important role in making decisions about their child's oral health as good oral health habits in childhood are shaped by parents. The aim of this study is to evaluate the awareness and knowledge of parents towards professional pediatric dental treatment and oral health care maintenance.

Materials and Method: A cross sectional questionnaire survey was conducted among 100 parents of 5 to 15 years school going, who visited Saveetha Dental College. A self administered questionnaire addressing various aspects of knowledge and attitude of parents toward pediatric dental treatment and oral health care was answered by participants. The data was first transferred into Microsoft excel spread sheets. The results were analysed by using SPSS statistical software and descriptive statistics was done. (statistical package for social sciences, SPSS Inc., Chicago, IL, USA).

Result: In the present study, Tooth brush and paste was the most common method of oral hygiene (94%), meanwhile only 5% use manual hand brushing. Most of the children (51%) brushed the teeth once a day, while 45% brushed twice a day. Approximately a half (45%) of parents supervised and advised for children during tooth brushing procedure. About 71% of the parents was unaware that pulp capping will be done for primary teeth. It also revealed that about 55% believed that there is spread of caries of from primary teeth to the permanent dentition. In

our study, most were aware that decay is preventable and only 29% were aware that fluoride prevents decay. When asked about the acceptance of preventive treatment if advised by the dentist, 28% were unsure or would not undertake preventive procedures for their children. This study revealed that most parents were not aware of the importance of dental visits at an early age.

Conclusion: Most parents had good knowledge regarding importance of primary teeth and oral hygiene maintainance, but the same did not reflect in their attitude and practice.

Key Words*: oral cavity, caries, pedodontist, oral hygiene, primary teeth*

Introduction

Health is understood to be "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity"(1) Health education is any combination of learning experiences designed to facilitate voluntary actions conducive to health. These actions or behaviours may be on the part of individuals, families, institutions or communities. Thus the scope of health education may include educational interventions for children, parents, policy makers, or health care providers. It has been well-documented in dentistry and other health areas that correct health information or knowledge alone does not necessarily lead to desirable health behaviours(2) .The oral cavity is the major part of the body and it is very important for the maintenance of good health. Oral health is having both healthy teeth affecting people physically and psychologically, its influence on their growth, function, speech, aesthetics, and socialization. Oral health is important for good health and well-being of individuals which covers a range of health promotion and disease prevention concerns(3). Oral health is an essential component of general health and influences a person's quality of life. Oral health behaviours play a central role in the prevention of many oral diseases. Oral health related habits are established early in life.

In early years of a child's life, the milk teeth plays an important role in speech, chewing, maintaining space and it also helps us in guiding the eruption of permanent teeth. Children should have a high standard of health, including oral health, but as children, they are dependent on adults for their health(4). Dental caries is the most common chronic disease of childhood and

may affect a child's quality of life due to various factors including pain, infection, sleep loss, absence from school with compromised education, poor mastication, compromised appearance, inadequate nutrition, growth and development. In industrialized countries, dental caries remains a significant public health problem.(5) Dental caries is a disease that generally is preventable by primary oral care measures, whereas dental treatment of carious primary teeth in children is expensive with further dental treatment being subsequently required in many young children who have had comprehensive dental treatment provided. Dental caries or its treatment in the primary dentition is a strong predictor for future development of dental caries in the primary, mixed and permanent dentitions(6). Paediatric dentistry is related to the child's psychology, to gain the child's confidence, and co-operation to perform the desired treatment in a kind manner. Paediatric dentist plays an important role in promoting child's future dental health by stimulating the attitude and behaviour regarding dental care (5).Most parents are unaware of the role a pedodontist and the importance of dental visits at an early age .The most parents have underestimated that the milk teeth are going to exfoliate and it not worth paying much attention without knowing the complication. Untreated dental can have serious impact on individuals, such as pain, discomfort, social and functional limitations, which ultimately can impair oral health-related quality of life (6).

Many dental health education programs have been conducted in schools and offices for the promotion of oral health care; however, but these efforts will not be succeeded until people are not aware of the importance of oral health and positive attitude towards the paediatric treatment modalities (7). Oral health education always begins with awareness of importance of oral health. The goal of oral health education is to improve knowledge, which may lead to adoption of favourable oral health behaviours that contribute to better oral health(8)The programs for the prevention of oral diseases concern teaching about oral hygiene and healthy eating, fluoride prophylaxis, periodic check-ups, sessions of professional oral hygiene, and secondary prevention programs. It is important issue which needs continuing supervision from the health care professional (9). Prevention of disease, disability and suffering should be a primary goal of any society that hopes to provide a decent quality of life for its people. Prevention on the community or population based level is the most cost effective approach and has the greatest impact on a

community or population, whether it is a school, neighbourhood, or nation. An effective community prevention program is a planned procedure that prevents the onset of a disease among a group of individuals (10). Many different approaches to preventing dental diseases exist and the most cost-effective method is health education. However knowledge gained may serve as a tool to empower population groups with accurate information about health and health care technologies, enabling them to take action to protect their health(11). A basic oral health care program introduced by World Health Organization for less industrialized countries includes oral health education and emphasizes on the integration of health education with other oral health activities such as provision of preventive, restorative and emergency dental care (12).The knowledge, attitude and behaviour of parents towards dental treatment tend to influence their child to accomplish a great dental attitude(13). So many oral health care programs must be implemented to achieve a wide spread of knowledge among the parents and their children(14). This study is to evaluate the awareness and knowledge of parents towards professional pediatric dental treatment and oral health care maintainence.

Materials and Method

Study Design

A cross-sectional study was conducted among 100 parents of school going childrens in the outpatient Department of saveetha dental college, Chennai,Tamilnadu. The study was conducted during the month of April 2016 after taking prior informed consent from the parents who were willing to participate. Inclusion criteria were parents getting their children treated for dental caries or had a past dental history and who were willing to participate. In addition, parents with children with no medical conditions or no medications prescribed to them were included in the study. Childrens age between 5 years to 15 years were included in the study. Age of 12 to 15 years seem to be accepted as a monitoring age for caries since all permanent teeth except third molars would have been erupted by this age. They seem to be more prone to dental caries at this age . Parents who could not read and write were excluded from the study. Parents who were not

the primary caretakers of their children or who had children with medical problems were excluded from the study.

Methodology

The self-administered questionnaire written in English was adapted from several studies. It had 22 questions, 8 each in the knowledge regarding oral hygiene instruction and 14 in the attitude of parents towards pediatric dental procedure, and took about 10–15 min to complete. The scoring for practice and attitude towards pediatric dental procedure included yes/NO/do not know responses and knowledge regarding oral hygiene were given options. All aspects of oral health promoting factors in children including oral hygiene, diet, and fluoride, and awareness regarding infant oral health and practices were addressed. This pretested questionnaire addressed the knowledge, attitude, and practices of oral health care for prevention of early childhood caries.

Result

Demographic data of participants are represented in (**Table.1)**.The results of answers are presented in (**Table.2)**. Tooth brush and paste was the most common method of oral hygiene (94%), meanwhile only 1% of participants answered that use mouthwash and 5% use manual hand brushing .Most of the children (51%) brushed the teeth once a day, while 45% brushed twice a day and 4% answered that brush less them once a day. Approximately a half (45%) of parents supervised and advised for children during tooth brushing procedure. Meanwhile 27% of parents were brushing children teeth, 16% of parents gave only advices and 12% did not participate in children tooth brushing. 84% of the parents believed that sweets can affect child oral health. 12% thought that sweets couldn't affect child oral health and 4 % didn't have opinion about this item.67% of the parents believed that oral health affect general health, while 26% of participants were thinking that oral health cannot affect on general health and 7% did not know. 69% of the parents changed their childrens brush 3 months once while 27% changed 6 months once and 4% changed yearly once. 39% of parents answered tongue cleaner was the most

common auxillary aid used where 62% had no practice of using auxillary aids. It also depicted that only 49% of the participants made their children to clean their tongue regularly.

Mostly 57% fathers filled the questionnaire whereas only 43% mothers filled the questionnaire **(Table.1)**

The result showed that **(Table.3)** 87% of the parents were aware that there are two sets of teeth(milk teeth and permanent teeth) while 13% responded that they were not aware of it. 55% have brought their childrens to dentist for check up whereas 45% of the parents gave a negative response. Most of the parents (71%) did not know pulp capping and root canal treatment will be done in childrens while 29% were aware about it. 73% of the parents responded they will go to pedodontist if they were referred, while 17% showed negative response and 10% had no opinion on it. 55% believed decay in the primary teeth will affect the underlying permanent teeth, whereas 25% said no and 20% had no idea about it. 39% of parents responded they will give preventive measure treatment such as fluoride and pit and fissure sealant if the dentist recommends but 33% said they will not take up any treatment for their childrens. Only 14% of the parents believed that application of fluoride to childrens once in 6 months will be resistant to decay and 86% showed affirmative response. 97% were not aware that pedodontist are well trained in behavioural management and also showed 84% of the parents were ready to receive more information about pedodontic treatments and oral hygiene maintainence for their children whereas 16% were not interested about it.

Table1: Demographic characteristic of participants

Demographic data	Number(%)
Female	43(43%)
Male	57(57%)
Total	100

Table 2: Distribution of study population about knowledge on oral hygiene instructions among parents

	Number	Percentage
Method of oral hygiene		
Tooth brush and paste	94	94%
Mouth wash	1	1%
Manual hand brushing	5	5%
Frequency of tooth brushing		
Once a day	51	51%
Twice a day	45	45%
Less than once	4	4%
Parents role in child tooth brushing		
Parents brush children teeth	27	27%
Parents supervise and advice	45	45%
Parents give advice	16	16%
Do not participate	12	12%
Sweets affects oral health		
Yes	84	84%
No	12	12%
Don’t know	4	4%

Does oral health affect general health		
Yes	67	67%
No	26	26%
Don't know	7	7%
Frequency of changing brush		
Once in 3 months	69	69%
Once in 6 months	27	27%
Yearly once	4	4%
Most common auxillary aids used		
Tongue cleaner	31	31%
Interdental brush	1	1%
Floss	6	6%
None	62	62%
Make your children clean their tongue		
Yes	49	49%
No	51	51%

Table 3: Distribution of study population on attitude of parents towards pediatric dental procedure

	Yes(%)	No(%)	Don't know(%)
Do you know we have two sets of teeth- milk teeth and permanent teeth	87%	13%	-
Has your child ever been to the dentist before	55%	45%	-
Are you aware of pediatric dentistry	57%	43%	-
Are you aware that pulp capping is done in milk teeth as well?	29%	71%	-
If you were referred to go to pediatric dentistry, will you go?	73%	17%	10%
Do you think infection from milk teeth can spread to permanent teeth lying under it and damage it?	55%	25%	20%
Do you think space between milk teeth is normal?	45%	24%	31%
Are are you aware Paediatric dentistry treatment can help to correct crooked teeth at a later stage?	51%	24%	25%

Do you think teeth decay can be prevented?	74%	9%	17%
Do you know that application of fluoride every 6 months can make your child's teeth more resistant to decay?	29%	14%	57%
If a dentist advises you for preventive treatment like sealants and fluoride application to prevent decay in child's teeth, would you do?	39%	33%	28%
Medicine syrups plays a big role in tooth decay, do you agree?	38%	32%	30%
Do you know pedodontist are well trained in behavioural management	3%	97%	
Would you like to receive more information about your child teeth protection and oral hygiene maintainable?	84%	16%	

Discussion

Parents are role models for their children. Children learn habits by imitating their role models and the best way to teach them is to practice these oral hygiene practices themselves.(15). Dental caries is a preventable disease and if it is noticed at an early stage.(16) Hence, prevention at the root level that is primordial prevention and oral health education of parents is essential as the preschool age group (2–4 years of age) is dependent on them for their oral health care needs. Later, from 2 years onward, oral health promotion strategies such as fluoridated toothpaste, etc., can be begun in cooperation with the parents. To attain these goals, one needs to assess the existing levels of knowledge, attitude, and practices to bring about the necessary changes. (17) In addition, children with primary dentition affected by dental caries are prone to the development of dental caries in permanent dentition. Hence, children reinforced at an early age by their parents are motivated and trained for a lifetime.

The role of bacteria in the causation of dental caries was not acknowledged by the majority of the parents which was reflected by the prevalent practice of sharing utensils and biting food into small pieces before feeding in this study. This is in accordance with studies by Mani *et al*.(18) The focus should be on parents/carers to encourage to limit their children practice of sharing utensils and biting food invited to carry out oral hygiene practices in a proper way carers and children should be advised that foods and drinks containing sugar substitutes are available, but should be consumed in moderation. Sugar-free medicines should be used when available. Parents and care takers should be encouraged to brush their child as soon as the first tooth appears, using a soft toothbrush and water only.(19) Meanwhile the results of this survey showed, Tooth brush and paste was the most common method of oral hygiene (94%), where the study conducted by Suvarna (20)showed 84% of the participants used tooth brush and paste, whereas 45% parents supervised and gave advises during children tooth brushing procedure in the present study which is more than the study carried out by Suvarna(20). More children brushed teeth twice a day (39%) when compared to previous study(20).There is generally failure in use of interdental auxillary aid. In a study conducted in Saudi Arabia in 2001 showed 64% of the subject did not use dental floss, interdental brush and tongue cleaner as an preventive auxillary aid which is similar to our results (21). Tongue cleaning was done by 49% of children in the present study which is in contrast with the study done by Jain et al(22) in which only 20% of the studied

population cleaned their teeth. Other studies by Al-Zahrani *et al*(23) also revealed that parents are aware of milk teeth and permanent teeth and also affect the general health of the child. In this study, it showed that 87% of the parents were aware of importance milk teeth and permanent teeth. Only an average of 57% of children visited dentist and were aware of pedodontist which also showed similar result in the study carried out by jain et al(22).

The study revealed, 84% of the parents believed that sweets can affect oral health of children. 12% thought that sweets couldn't affect child oral health and 4 % didn't have opinion about this item. 67% of the parents believed that oral health affect general health, while 26% of participants were thinking that oral health cannot affect on general health and 7% did not know about it. Al-Zahrani et al(23) also showed similar results that average of 64.5% of the parents believed that oral health has an impact on general health and sweets can affect oral health.

In the present study, most of the parents (71%) did not know pulp capping will be done in children while 29% were aware about it. The study conducted by MCknight et al,(24) showed 63% were not aware of pulp capping treatment which is comparatively lesser than our present study.73% of the parents responded they will go to pedodontist if they were referred. 39% of parents responded they will give preventive measure treatment such as fluoride and pit and fissure sealant if it was recommended by the dentist. Meanwhile 33% said they will not take up any treatment for their childrens. This results were similar to the study conducted by Zahrani et al et al(23) where 38.5% of parents agreed to take up the preventive treatment if the dentist suggests. Only 55% of the parents were aware that infection from a primary teeth can spread to the permanent tooth underlying underneath it and damage it. This findings is comparable to the studies conducted by Al Zahrani et al (23)who reported 71% were aware of the same. In our study most were aware that decay is preventable and only 29% were aware that fluoride prevents decay. This was contrary to the study conducted by suresh et al,(25) where the parents knowledge about fluoride was inadequate. In the present study 62% of the parents were unaware that medicated syrups may lead to dental decay. This finding is similar to the other studies conducted by H Landt et al(26). 97% were not aware that pedodontist are well trained in behavioural management and also showed 84% of the parents were ready to receive more

information about pedodontic treatment and oral hygiene maintainence for their children. This was similar to the study conducted by H Landt et al(26).

From the present study, regarding the importance of maintenance and management of their children's dental health which signifies a genuine lack of awareness than an attitude of indifference towards importance of primary teeth. This indicates that improvement of basic knowledge and dental health education is mandatory in our population.

In conclusion, many parents had good knowledge, but the same did not reflect in their attitude and practice. It is worthwhile to attempt regular oral health promotion education programs, with stress on prevention and treatment modalities for their children.

Abstract

Introduction: Digital imaging modalities which are recently developed offer better options by significantly reducing the dosage of radiation exposed and at the same time offer better quality with user- friendly options. Such things must be made known to the dentists who will in turn benefit the patient as well. The aim of this study was to determine the knowledge and attitude towards digital radiography among dentists.

Materials and Methods: A systematic random survey of practicing dentists in Chennai using a questionnaire with questions pertaining to individual details, knowledge level and approach toward digital radiography. A total of 50 dentists were included in the survey.

Results: In this study, it was found that majority of the dental practitioners prefer digital imaging modalities in their practice. However, detailed knowledge regarding the digital imaging remains unknown to some.

Conclusion: Proper precautions need to be taken by the dentists during radiation exposure, which has to be made known to them, and also the various advances in the digital imaging modalities, which provide better options for the dentist as well as the patient.

Key Words:*Advances, Digital imaging, Dentists, Knowledge, Radiation*

Introduction

The selection of an ideal diagnostic technique is an essential step in the treatment of a disease. An ideal diagnostic tool will provide the essential information, while minimizing the cost and adverse effects to the patient. Radiographs are valuable tools in diagnosis and treatment prognosis in various fields of dentistry. The discovery of Xrays was done by Wilhelm Conrad Roentgen in the year 1895. The first original roentogram was taken by Dr. Otto Walkoff in January 1896 from a portion of a glass imaging plate for an exposure time of 25 minutes in his own mouth. Ever since, imaging in dentistry has seen a major progress and is applied in various fields of dentistry. [1] As a result of rapid developments in the field of dental imaging and technology, the use of digital imaging has found to be increased over the past years.

Both intra oral radiographs and extra oral radiographs are being used to help in diagnosis and treatment is various fields in dentistry. Two dimensional and three dimensional radiographs are used in diagnosis and treatment panning. 2 Dimensional radiographs provide excellent insight into the internal structure of the teeth and the supporting structures and hence can be used in the diagnosis of dental caries, periodontal and periapical lesions and osseous defects as well.Intra oral radiographs give a picture of the tooth and the internal components, the periodontal structures and the surrounding alveolar bones. Extra oral radiographs which include the lateral cephalometric radiograph show the structural relationship between the bones, the maxillary and the mandibular jaw bones, and the airways spaces.

Conventional imaging modalities which require a detailed processing have been developed in such a way to minimize the processing time and to fasten the image reception process.Attempts have been made in dental imaging to develop techniques that provide optimal information, while minimizing harm to the exposed patient. [2] Most practitioners favor the use of digital radiographic techniques which have many advantages, which include time effectiveness, use of low radiation dosage, elimination of requirement of chemicals and development processes, and have storage capacity and easier ways to communicate with other dentists also. [3] There are also disadvantages with the use of digital imaging, such as high cost for installment and maintenance, and in some cases, even the radiation dose.

Imaging modalities such as Computed Tomography(CT) and Cone Beam Computed Tomography(CBCT) have been developed with the aim of reducing radiation exposure of the

patient and limit the exposure to the head and neck region. CBCT works on the principle that by focusing a cone shaped X-ray beam on a two- dimensional (2D) detector that rotates 360^0 or less around the patient's head to produce a series of 2D images which is then studied. CBCT was introduced with the benefit of having a lesser cost factor, require lesser installation space and have a rapid scan time and limited area of exposure only to the head and neck. Drawbacks of CBCT include beam hardening and scatter from dental materials and poor soft tissue contrast.[4]Although it could be assumed that the radiation dose levels in dental practice are relatively low and not harmful to health, the cumulative effect of repeated exposures must be considered. It is necessary to determine the level of knowledge of dental practitioners, quality care, radiation protection and whether they are being used efficiently in oral and maxillofacial radiology. The aim if this study is to evaluate the knowledge and attitude of dentists towards radiation hazards and protection, the various digital radiography methods and the recent advances in the field of digital imaging.

Materials and Methods

The present survey was undertaken among practicing dentists in various areas in Chennai. The institutional ethical clearance was obtained prior to the start of the study. A questionnaire with 15 questions was administered to a total of 50 dentists and collected personally. The questionnaire comprised of questions regarding the use and preference of digital imaging modality, knowledge regarding radiation dosage, precautions taken and their attitude towards developments in dental imaging techniques. A comprehensive questionnaire was prepared based on a study done in Mangalore, India. [5]. All the dentists who undertook this survey were explained in detail about the purpose of this study and were assured about the anonymous processing of the questionnaire. The questionnaire comprised of the following sections of questions such as Demographic details which includes age, sex and work experience; Duration and reason for usingdigital radiography; Radiation protection which includes the use of protective barriers and knowledge regarding radiation safety and knowledge about recent advances in digital imaging

The results were obtained and the statistical analysis was done and tables were drawn with the analyzed data.

Results

The mean age of the respondents was found to be 35. In this study, it was found that 69.76% of the respondents started using digital radiography in routine practice less than the past 5 years, 27.9% for the past 5 years and 4.6% more than past 10 years. Intra oral radiographic examination us the backbone of imaging for a dental professional. However, despite the increased usage over the past few years, the knowledge regarding the maximum permissible dosage for digital imaging was not well known.

Less radiation dose	30.43%

The safe distance from the radiation exposure was known by around 64.4% of the dentists who undertook the survey. 55% stated that they use CBCT for implant placement, 25% in orthodontics and 6% in the evaluation of cysts and tumors. Periodic checks of the radiography equipment were said to be done by 51% of the respondents. The advantage of CBCT over CT was stated to be because of the low radiation dose (58.8%), continuous image can be obtained (17.6%) and also because of its high accuracy and high resolution. In this study, the reasons for using digital radiography was found to be less radiation dose (30%), short time required for image processing (30%), no development required (8%), measurements and adjustments can be made (4%) and others (2%). (Figure 1).The commonly used digital radioprahic methods as found in this study were IOPA (84%), Bitewing radiograph (8%), OPG (2%) and CBCT (2%). (Figure 2).The most commonly employed method of radiation protection was the use of lead aprons (30%) and a protective barrier wall (30%). (Figure 3).The easiest to manage in a dental office was said to be IOPA- 75%, followed by OPG- 13% and CBCT- 4%. (Figure 4). Also,57.7% said that they were not aware of the recent developments in the field of dental imaging using digital radiographic techniques, and would like to update themselves through the internet (37.14%), journals (28. 2%), conferences (25.7%), and others (8.5%). (Figure 5)

Table 1: Reason for using digital radiography

Short time	30.43%
Easy to store	26.08%
No development required	8.69%
Adjustments and measurements can be made	4.34%
Others	2.17%

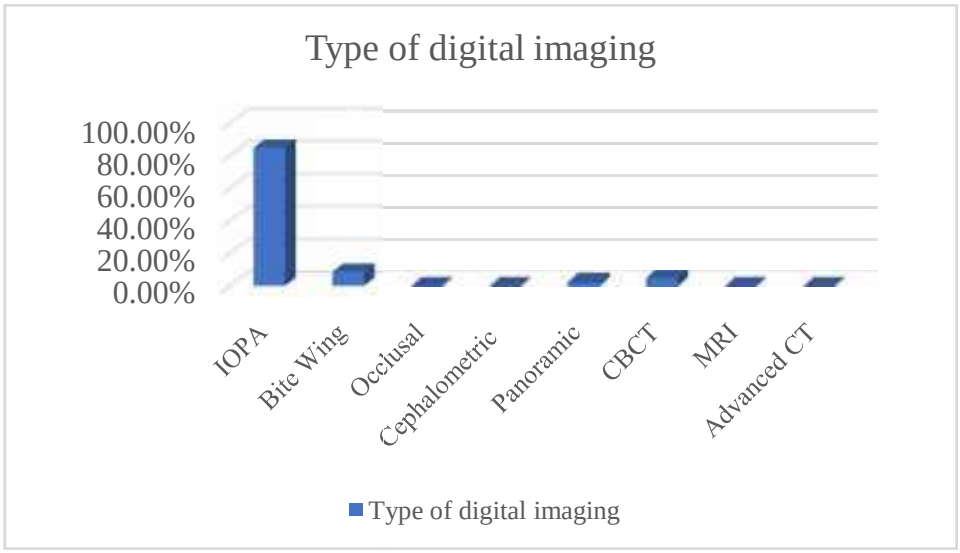

Figure 2: Distribution of various types of digital imaging modalities being used

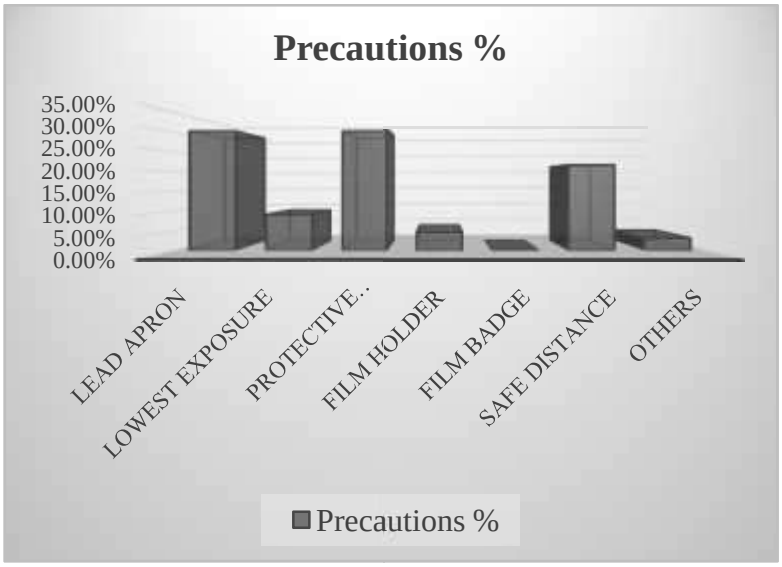

Figure 3: Radiation protection methods being practiced by the dentist

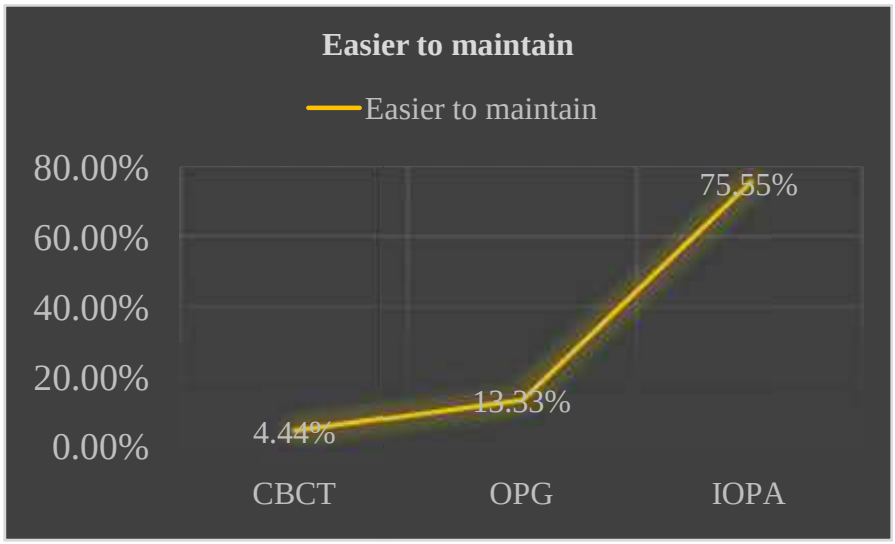

Figure 4: Mode of digital imaging modality is easier to maintain in practice

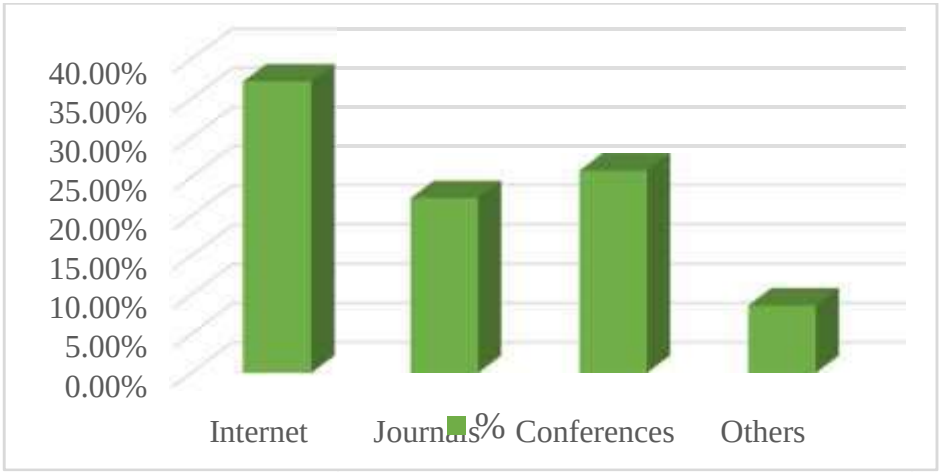

Figure 5: Distribution of dental practitioners willing to enhance knowledge regarding advances in digital imaging techniques through various modalities.

Discussion

The data shows that the preference of digital radiography is increasing among dentists over the past years. Among the participants of this study, 69% have started using digital radiography over the past 5 years alone. Wenzel and Moystad in 2001 reported the use of

digital radiography in 2001 as 14% of their sample, and compared with the 67% in a 2011 study by Dolekoglu et al. [6]This shows that the use of digital imaging modalities has probably increased over the years with the advancement in technology.Also, dental practitioners who have recently graduated were found to be more familiar with digital radiographic examination, considering the recent development of digital technology. A similar result was obtained by Karla Rovaris et. al who conducted a survey in Brazil to investigate the use and acceptance of digital radiographic examinations by dental practitioners in Brazil, which also is a developing country like India. [7]

The various types of intra oral radiographic methods used are: periapical, occlusal and bitewing radiographs. The periapical radiograph provides diagnostic information involving the tooth and periapical regions. The occlusal radiograph helps to visualize a larger pathology like a cyst which cannot be visualized by any other radiographic method. The bitewing radiographs help to evaluate the interproximal regions of adjacent and opposing teeth simultaneously. The extra oral radiographic methods used in dentistry include panoramic radiographs, lateral skull view, Posterior- Anterior View and Lateral Cephalogram. CBCT is another imaging technique which is a recent development and has proven to have better accuracy in determining the extent and location of anatomical structures and defects in the teeth and surrounding structures.

Also, digital imaging has profound advantages than conventional imaging modalities. It has been stated that the amount of dose reduction for intra oral digital imaging is about 50%- 60% when an E- speed film is used. Other advantages include short processing time, elimination of a dark room, chemical handling and errors associated with developing the film image.A study was done by Mohammed Mahdi et. al to compare the accuracy of conventional and digital radiography in root canal working length determination and the results of the study state that there was no difference observed when using CCD, PSP and conventional imaging techniques.[8]The safe distance from the radiation exposure was known by around 64.4% of the dentists who undertook the survey. In a similarstudy done by Katarzyna et. al to assess the knowledge regarding digital radiography and CBCT, it was found that the radiation awareness among dentists in inadequate. [9]

The most commonly preferred imaging modality for the 3D imaging of the head and neck region was stated to be CBCT (47.7%). CBCT processes two dimensional cone- beam projections and provides a 3 Dimensional full volumetric reconstruction so the target area

can be assessed in all planes. [10]CBCT has profound uses in dentistry, which includes the localization of supernumerary teeth, detection of cysts and tumors of the jaw, assessment of root canal configurations, detection of root fractures, treatment planning for placement of dental implants, peri- implant bone defects and orthodontic diagnosis.[11]Another study done by Keerthana et. al has stated that about 82% were aware of CBCT being used in maxillofacial radiology. [12] The Periapical lesions become visible on radiographs only when 30-60% of mineral bone loss has happened. When such peri apical lesions are covered by a thick cortex or cancellous bone, they could be radiographically undetectable. Two dimensional images restrict the information regarding the size and extent of the periapical lesion. In such cases, a three dimensional image is essential which is provided by the Cone Beam Computed Tomography which is not considered as the gold standard in endodontics. [13] CBCT is said to give all the information as given by a CT, at just $1/8^{th}$ of the radiation dose. [14]However, maintenance and installment of CBCT is not very easy. In this study, 40% had stated that they did not know the maximum permissible dose of radiation for a dentist. This has to be addressed with prime concern because knowledge regarding the permissible dosage is essential to limit and prevent damage to the body cells which are caused by radiation exposure.Some epidemiological studies show that there is no increased risk of cancer among the dentist population, whereas other studies show a higher prevalence of thyroid and breast cancer among female dentists and of melanomas in male dentists. [15] This brings us to a decision that knowledge regarding the safety dosage limit and precautions has to be well known by dentists in order to prevent any systemic complications. In this study, 51% of dentists have stated that they use radiation protection equipments in their daily practice. However, a majority of dentists at large are not making use of protective equipments. This has to be treated with concern and knowledge regarding radiation protection must be emphasized.

Conclusion

Recent developments offer better quality imaging which has to be made known to the dental practitioners. Dentists should prescribe special imaging only when they expect that diagnostic yield will benefit the patient care and improve clinical outcomes significantly. More awareness of the radiation protection and knowledge about the safe dosage and

distance has to be made known to the dentists to ensure maximum benefit as well as as low as harm possible.

Abstract

Introduction: Root canal treatment (RCT) is taken into account as a necessary component within the dental services provided to the population in developed furthermore as developing countries.It is the responsibility of the academics and dental schools to prepare their students to adopt the guidelines and recommended standards in root canal debridement, shaping and obturation..The aim of this questionnaire survey was to evaluate the knowledge and practice of endodontic treatment carried out by general practitioners in Chennai.

Material and Method: A questionnaire was developed with 15 questions based on knowledge and practice ofendodontic treatment and was sent to 50 general dental practitioners (n = 50). The collected data were entered into a personal computer and analyzed.

Results: In the present study all the participants, i.e. 100% reported that they perform root canal procedures in posterior teeth. Isolation was mainly done using rubber dam in 32%of dentists. The step back technique was the most popular root canal preparation technique (76%).42% of dentists in Chennai tended to use hand instruments and 40% of the themprefer K-files for cleaning and shaping the root canals. Every dentists in Chennai take radiographs in every steps of RCT. 58% of dentists used normal saline for irrigation.Every dentists reported that, they use gutta- percha as obturating material with 52% of them used lateral condensation technique.Every dentists used Zinc- oxide eugenol as sealer. The coronal access cavity was sealed by temporary restorative material immediately after the treatment and the permanent sealing was done later on by themselves.

Conclusion: Based on this survey, it was demonstrated that dentists performed procedures which often deviated from well-acknowledged endodontic quality guidelines. General practitioners did not seem to keep up with recently introduced techniques, but use more conventional methods. Most of the conventional techniques used by dentists were reported to have increased success rate.

Key Words: *Endodontic treatment, isolation, irrigants, instruments, obturation, filling material.*

Introduction

Endodontic treatment is an essential part of comprehensive quality dental care. Root canal treatment (RCT) is defined as the combination of mechanical instrumentation of root canal system, its chemical debridement and filling with an inert material, designed to maintain or restore the health of the peri-radicular tissues. The manner of execution of treatment procedures is so diverse even within prescribed protocols that it is difficult to define it any more precisely and it is accepted that this treatment intervention is not by its nature standardizable. [1,2]

The goal of endodontic and restorative therapy is to restore the normal function and occlusion of the tooth and to maintain the stability of the dental arch. The strength of the endodontically treated teeth is directly connected to the bulk of the remaining dentin. Root filled teeth with intact coronal structure have a good long term prognosis [2,3]. Several studies have revealed that the majority of dentists do not comply with the formulated guidelines on the quality of RCT[4-7]. It is the responsibility of the academics and dental schools to prepare their students to adopt the guidelines and recommended standards in root canal debridement, shaping and obturation [1,3] .The rationale of this study was to evaluate the practice and knowledge about root canal treatment of molar teeth by private general dental practitioners in Chennai. The purpose of the questionnaire was not only to collect baseline data, but also to determine the endodontic knowledge and practice of dentists. Furthermore, it was hoped to gain an insight into potential problems regarding endodontic treatment procedures that could explain the present standard of RCT carried out by general dental practitioners.The aim of this cross-sectional survey was to evaluate the knowledge and practice of endodontic treatment carried out bygeneral practitioners in Chennai.

Material and Method

A survey on general dental practitioners in Chennai was carried out to investigate common materials and methods employed in RCT. A questionnaire was developed with 15 questions based on knowledge and practice about endodontic treatment and was sent to 50 general dental practitioners (n = 50). The collected data were entered into a personal computer and analyzed. The questionnaire consisted ofquestions concerning different aspects of endodontic

treatment including the provision of root canal therapy stages, materials, the choice of instruments, isolation methods, radiographs taken throughout the treatment, the use of canal irrigants and intracanal medicaments, the choice of obturation technique, temporary and permanent coronal restoration, and case monitoring and follow-up. The collected data were entered into a personal computer and analyzed.

Result

Based on the questionnaire survey, it is found that , all 50 practitioners performed RCTby themselves including molar root canal treatment(100%). The practitioners did not use rubber dam for all the treatment. Considering the frequency of usage 90% dentists reported occasionalusage of rubber dam(90%). Almost everyone preferred to take radiograph in every step of the treatment. Gutta-percha (100%)was the only material used by every dentist in Chennai to obturate with zinc-oxide eugenol (100%)as sealer. The coronal access cavity was sealed by temporary restorative material immediately after the treatment and the permanent sealing was done later on by themselves.

Discussion

The reason for this study was to gather both qualitative and quantitative information on endodontic treatment by dentists working in Chennai and to analyze the advantages and disadvantages of each. In the present study all the participants, i.e. 100% reported that they perform root canal procedures in posterior teeth. The use of rubber dam is always recommended during root canal treatment to provide isolation, protection and improve visibility, 32% of dentists reported using rubber dam occasionally while, 30% of dentist use cotton rolls for isolation. However, 59% of American dentists [9] , 60% of dentists in UK and 57% dental practitioners in New Zealand [10,11] reported using rubber dam during every endodontic procedures.The reasons for not using rubber dam could be the extra cost, additional time, lack of adequate skills or training, absence of patient's acceptability or inadequate education in the undergraduate teaching curriculum [12]

The step back technique was the most popular canal preparation technique among general dental practitioners for about 76%. The filing (push-pull) technique, on the other hand, was used by only 6 % of the dentists. Whereas, 18% of dentists use step down technique. Generally, dentists in Chennai tended to use hand instruments 42% and 16% of dentists use engine driven techniques for shaping the root canal system, while 42% of dentists reported using both. Most of the dentists prefer K-files are used for shaping the canals(40%), 20% of dentists use Reamers and K-files, and very few doctors use H- files(2%). 38% percentage of dentists use all three instruments for better quality of treatment. Every dentists in Chennai take radiographs in every steps of RCT. In the current survey, most general dental practitioners used normal saline(58%) as root canal irrigant, 20% of dentists in Chennai usedchlorhexidine as intracanalirrigant, while 14% used sodium hypochlorite. The material of choice for irrigating the root canal system wassodium hypochlorite because of its effective antimicrobial and tissue solving action. However, using sodium hypochlorite or hydrogen peroxide without isolating the field of operation with a rubber dam presents a hazardous practice. A similar trend ofusing sodium

hypochlorite as a root canal irrigant without using rubber dam for isolation, was noticed amongst Flemish dentists [6]. A very few practitioners use hydrogen peroxide as irrigant in endodontic treatment.

Absolutely every dentists in Chennai use gutta-percha points as obturation material in endodontic treatment. 52% of dentists used lateral condensation technique for obturation which had increased success rate, where 48% used single cone technique which is easier and less time consuming. Cold lateral condensation of gutta-percha in conjunction with a root canal sealer is the most widely accepted technique for obturating root canals[13]. It is a relatively simple and versatile technique that does not require expensive equipment. It is therefore not surprising that it is the technique used by the majority of responding practitioners (especially the younger ones) in their general practice. Single-cone/point techniques cannot reliably fill all the root canal space in three dimensions and are not recommended, although this technique was practiced once upon a time. Similarly, paste only root fillings are difficult to control with the obvious risk of under- or over-filling of the canal. This is particularly problematic with paraformaldehyde-based sealers, as they can cause extensive damage to the peri-radicular tissues [14-16]. The trend is toward the use of warm gutta-percha techniques to improve the filling of accessory anatomy such as fins and apical deltas[17]. However, 31.3% of the dentists in Jordan used a single cone technique, in common with 68% of Swiss dentists[18]. The temporary filling material after endodontic treatment used in most common is zinc oxide eugenol by 54% of doctors, and 46% use intermediate restorative material as temporary filling material.

Based on this study, the number of practitioners using inappropriate techniques/materials was quite small and there are possibilities of changing behavior with education to bring successful results [19-23]. This study sheds light on current preferences for various endodontic materials and techniques. It also notes the potential possibility for educational interventions.

Conclusion

Within the limitations of this study, itwas demonstrated that dentists performed procedures which occasionally deviated from well-acknowledged endodontic quality guidelines. General practitioners seem to use more conventional methods. It is recommended and vital to impart higher level of continuing dental education for general practitioners to update their knowledge in the field of endodontics.

Knowledge of Undergraduates in Dental Radiology

M.Indhumathi[1], Shantha Rajan[2],Hemavathy.O.R[3]
Graduate Student[1],Senior Lecturer[2], Department of Pedodontics,Reader[3], Department of Oral and Maxillofacial Surgery
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Dental radiographs are important tools in the diagnosis of oral diseases.It helps the dentist for appropriate treatment for patients and dental conditions and play a continual role in dental practice.So it's availability in dental clinics are very important for dental procedures.Radiation dosage from such dental radiographs are low and it shows minimal risk in patients. The aim of the study is to evaluate the knowledge of under graduates in dental radiology.

Materials and Methods: The study was conducted in Saveetha dental college, chennai, India. The study was conducted among78 final year dental students, of which 46 were females and 32 were males. This was cross-sectional questionnaire based study on radiation protection among dental students. Correct responses to the questions were allocated 1 mark while wrong response received no mark. Statistical analysis was performed to analyse the study.

Results: Among 78 final year students, who participated in the following study,only57(83.3%)students were aware of radiation protection and about 21(27.2%) students should improve their knowledge of dental radiation.

Conclusion: There is need to expand the curriculum to provide better exposure to radiation protection and its practice, so that the dental students on graduation will be well grounded with the principle governing dental radiography.

Key Words: *Assessment, dental students, knowledge, radiation protection, radiation practice*

Introduction

Dental radiographs are important tools in the diagnosis of oral diseases. It helps the dentist to employ appropriate treatment regimen for patients' dental conditions, and plays a continual important role in dental practice. Hence its availability in most dental clinics is considered crucial. Radiation dosage from such dental radiographs are low and are thought to present minimal risk.It is estimated that about 480 million dental radiographs are performed annually accounting for approximately 15% of all diagnostic X-ray examinations.[1]Consequently concern radiation biology and protection and radiology of oral diseases among other topics.These students are also exposed to clinical postings in the oral diagnosis and radiology clinic for a period of 4 weeks in the 5th year . On completion of the course, the undergraduate student is expected to be able to explain the production of ionizing radiation, image formation and principles of radiation biology and protection from effects of ionizing radiation to oneself, clinical staff and patients.[3] Eventually these dental students would metamorphose to dentists and may perform dental radiography in their clinics. Their knowledge and practice on dental radiography are consequently crucial. [2]

Dentists take radiographs in the evaluation of their patients. During undergraduate and post graduate training dentists are trained to perform dental radiographic exposures particularly during clinical rotations. In India students are allowed to take dental radiographs under supervision. The undergraduate dental training in Saveetha dental college is divided into the pre-clinical levels ($1^{st}$and 2^{nd}year) of study and the clinical levels (3rd, 4th and 5thyear) of study. In the institution where this study was carried out the fifthyear curriculum of dental students includes two schedules each of lectures in dental radiology with the second schedule of the fifthyear having basic radiation physics, the production of X-rays, radiation biology and protection and radiology of oral diseases among other topics.[3] These students are also exposed to clinical postings in the oral diagnosis and radiology clinic for a period of 4 weeks in the 5th year.. On completion of the course, the undergraduate student is expected to be able to explain the production of ionizing radiation, image formation and principles of radiation biology and protection from effects of ionizing radiation to oneself, clinical staff and patients.[3] Eventually these dental students would metamorphose to dentists and may perform dental radiography in their clinics. Their knowledge and practice on dental radiography are consequently crucial. [4]

Materials and Methods

This is a cross-sectional study on radiation protection conducted at Saveetha dental college. A four section questionnaire was administered to volunteering final year dental students at the Saveetha dental college. The questionnaires were collected after being filled by the students within the hour of administration with all the students seated and interaction between students discouraged. Correct responses were allocated 1 mark while wrong response receives no mark. [5] No point was subtracted for wrong responses. There was no student identifier in the questionnaires. The first section consists of socio-demographic data and questions bordering on if the students had previous exposure to formal lectures on radiation protection and pre-medical school graduate certificate. The second section consists of questions on radiobiology while the third section was on radiation protection. The fourth section was meant to test good radiation protection practice and also contains other questions such as if the students feels that their knowledge on radiation protection was adequate and the kVp of the machine they use. Each of the second, third and fourth sections have five questions each for assessing that section. Radiobiology, radiation protection and practice scores were categorized into; 0 to 2 points (poor), 3 points and above (good).The correct responses of radiobiology (section 2) and radiation protection (section 3) were summated to yield ‘‘total knowledge on radiation protection’’ which was subsequently graded into ‘‘poor’’ (0 to 4 points) and ‘‘good’’ (5 to 10 points). Statistical analysis was performed using SPSS version 17 (Chicago, IL). Pearson’s coefficientcorrelation analysis was performed to establish relationship between various variables with the significant level set at 5%.[6]

Results

The study was conducted among78 final year dental students, of which 46 were females and 32 were males. The mean score of the students on knowledge of radiobiology was 1.85 ± 1.19 (of 5 points). The proportion of students with a score of 2 points was the most, accounting for 22 (28.2%) of all the students. None of the students correctly answered all the questions on radiobiology. In comparison to the knowledge of radiobiology, knowledge of radiation protection was abysmally poor as the mean score was 0.92 ± 0.80 (of 5 points) while the modal score was zero point (accounting for 24 (30.8%) of the students). Only one student correctly ranked the effectiveness of the methods of protecting patients. Surprisingly,

none of the student knew the correct annual radiation dose limit for a dentist and only 14(17.9%) of the total number of students correctly knew what each of the acronyms of ALARA stood for. [8]Overall, the mean of the total (sum of radiobiology and radiation protection scores) score by the students was 5.45 ± 2.66 (of 10 points) and the modal score was 3 points (23.1%). No student was observed to have a score of 10. On categorizing the total knowledge of radiation protection, 12(15.4%) students had ‘‘good’’ score while 66(84.6%) students had ‘‘poor’’ score. Although none of the students used film badge, the other indices tested showed that they had good radiation protection practice knowledge — [Table 1]. The mean score of radiation protection practice was 2.69 ± 1.42 (of 5 maximal points) and modal score of 4 points (39.7%). The proportion of students with ‘‘good’’ radiation protection practice rating was 50 (64.1%) whereas 28 (35.9%) had ‘‘poor’’ rating. Undermining that 52 (66.7%) of the students responded that they used the lowest possible settings during dental radiographic exposure on patients, only 2 (2.6%) actually knew the kVp of the machine used in the department. The mean radiographs taken by these students monthly were 12.87 ± 8.8 with 53 (67.9%) students taking an average radiographs of 0 to 9 per month (‘‘poor’’ rating) and 25 (32.1%) took over 9 radiographs/month (‘‘good’’ rating). There was no significant correlation between the number of radiographs taken and knowledge of radiation protection or practice. A greater proportion of students with ‘‘good’’ radiation protection knowledge in comparison to those with ‘‘poor’’ knowledge kept a distance of over 3 metres from the patients/X-ray tube [7 (58.3%) vs. 34 (51.5%)], wore lead apron [12 (100%) vs. 54 (81.8%)], used the lowest possible settings on the x-ray machine [11 (91.7%) vs. 41 (62.1%)] and used collimators [10 (83.3% vs. 40 (60.6%)] — Table 1. Of the preceding tested parameters of radiation protection practice those that used the lowest possible settings was at statistical significant level, P = 0.046. Most 59 (75.6%) of the students thought they did not have adequate knowledge on radiation protection.

Radiological investigations should only be prescribed by medical personnel for specific purposes when the benefit outweighs the risk. Thus, it is imperative that the dentist ensure that adequate justification for the dental radiograph is met and that minimal permissible exposure is given. These dentists should be knowledgeable on radiation protection in order to properly protect the patients, themselves and others around them and their knowledge of ionizing radiation from medical devices makes explanation of the benefitand risk to the patients easy. In order to assess knowledge on radiation protection it is pertinent to establish the level of awareness on radiobiology. These students had an appreciable degree of

knowledge on radiobiology. Radiation causes cell damage by ionization with the consequent formation of ions that can produce free radicals, break chemical bonds, creates cross-linkage between macromolecules or damage molecules and genes. [9]

Table 1: Questionnaire

Radiation causes cell injury by?	Thermal effects 18 (10.3%)	Radio frequency 20 (24.4%)	Ionization 35(43.6%)	I don't know 10 (21.8%)
Susceptible cells to radiation are usually;	Somatic cells 18 (23.1%)	Rapidly dividing unspecialised cells 41 (52.6%)	I don't know 19 (24.4%)	
Cell damaged by radiation:	Cannot be repaired 25 (32.1%)	Is reparable 15(19.2%)	Always leads to cell death 18 (23.1%)	I don't know 20 (25.6%)
Which of the following radiation sources affects normal people the most?	Industry 33 (42.3%)	Medical 13 (16.7%)	Natural sources 15 (19.2%)	I don't know 17 (21.8%)
Foetal tissues are susceptible to radiation especially during: Radiation protection	<20 weeks 42 (53.8%)	20 to 30 weeks 11 (14.1%)	30 weeks to term 2 (2.6%)	I don't know 23 (29.5%)

How much radiation does a patient absorb during a single peri-apical x-ray exposure?	0.2mSv 2 (2.6%)	4 (5.1%)	0.005mSv 8 (10.3%)	I don't know 62 (79.5%)

Discussion

Table 3: Radiation protection practice

	Yes	**No**
Keep a distance of greater than 3 meters from the patient:	41 (52.6%)	37 (47.4%)
Wear a lead apron:	66 (84.6%)	12 (15.4%)
Use lowest possible setting possible:	52 (66.7%)	26 (33.3%)
Use film badge:	0 (0%)	78 (100%)
Use cone collimator:	50 (64.1%)	28 (35.9%)

Examples of such rapidly proliferating cells are found in foetuses; hence the developing foetus is particularly sensitive to the effects of radiation especially 2-9 weeks after conception which is the period of organogenesis.[15] for health care workers is 50 millisieverts (mSv) and the maximum permissible life time dose is 10 mSv multiplied by a person's age.[1] Concerning peri-apical radiograph dose, only 10.3% of these students could estimate the average radiation dose during a single peri-apical exposure. The effective dose from intra-oral peri-apical radiograph is 0.005 mSv.[14] Gijbels et al.[15] further determined the effective dose from peri-apical radiographs with rectangular collimation as 0.001 mSv (anterior), 0.001 mSv (lateral) and 0.003 mSv (posterior) while for round collimation the values were 0.001 mSv (anterior), 0.002 mSv (lateral) and 0.005 mSv (posterior). Hence, rectangular collimators reduce the radiation dose to patients when compared to conical collimators. Contrary to the earlier observation that these students have poor knowledge on radiation protection, majority (67.9%) of the students correctly opted to protect the thyroid gland rather than the brain or nostril during head and neck radiography. In the head and neck region the thyroid gland is one of the most sensitive organs.[6] Sikorski et al.[13] documented that radiation exposure reduction by thyroid shield varied from 5% to 56% for a complete-mouth survey, 2% to 18% for a bitewing survey, and 10% to 79% for a panoramic survey. In addition, their study showed that thyroid skin exposures measured on adults were 33% to 84% lower in offices in which thyroid shield was used as compared to offices in which it was not used and thyroid skin exposures measured on children were 63% to 92% lower. As a result it is highly recommended that leaded thyroid shields should be employed in children.[5] In comparison, knowledge on radiation protection was poor. Only one student knew the correct order of sequence for the effective radiation protection of patients for dental radiography. The most effective method is to reduce repeat rate, followed by the use of modern fast fi lm, thyroid shield utilization and finally lead apron. Reducing repeat rate comes with experience, adequate training and application of standard radiation protection practices with proper departmental quality control programme.[18] If no repeat radiograph is taken then there will be no additional undue exposure to radiation of the patients. Consequently, the exposing health professional should apply the appropriate settings and be familiar with the optimal settings to use. The use of faster fi lm speed can also reduce radiation exposure to about 50% while maintaining the diagnostic quality.[12] Poor knowledge of the meaning of ALARA was observed, as only 17.9% of the students actually

knew what the acronyms meant. It can be deduced that these students who were unfamiliar with the term may not be able to apply the principle of ALARA in practice. Consequently, patients may receive unnecessary radiation dose if the ALARA principle is not put into practice. Furthermore, none of the students knew the annual radiation dose limit for dentist. The maximum permissible annual dose of ionizing radiation Sixty-four percent of the student had good radiation protection practice while 367% had poor knowledge, an observation incongruous to knowledge on radiation protection assessment. None of the students had a thermolumincent dosimeter (TLD) badge despite some performing up to an average of 40 dental radiographs per month. Although 52.6% of these students kept a distance of at least 3 meters to the radiation beam, there is still some radiation dose absorbed from scatter radiation.[17] The direct and scatter radiation dose to the patient as well as the scatter radiation to the imager are considered very low, however some studies showed evidence of increased risk of brain, salivary gland, and thyroid tumours from dental radiographic exposure.[10] It is therefore crucial that other means of reducing radiation dose be employed. The use of collimation further reduces patients' primary and scattered radiation. Collimators are like aperture of a camera that reduces the field of irradiation and are typically conical/circular or rectangular. Rectangular collimators are five times more effective at reducing the radiation dose compared to conical collimators.[4,13] Consequently collimators should be provided in every dental radiographic unit, especially rectangular type. In the center where this study was conducted, rectangular and circular collimators are available, but the circular type is more commonly used.

Table 4: Cross-tabulations of total knowledge of radiation protection against radiation protection practise indices

Total knowledge classification	**Good**	**Poor**	**Total**
Keep a distance of >3m from patients			
Yes	7 (58.3%)	34 (51.5%)	41 (52.6%)
No	5 (41.7%)	32 (48.5%)	37 (47.4%)
Total	12 (100%)	66 (100%)	78 (100%)
			P=0.663

Wear lead apron Yes No Total	 12 (100%) 0 (0%) 12 (100%)	 54 (81.8%) 12(18.2%) 66 (100%)	 66 (84.6%) 12(15.4%) 78 (100%) P = 0.108
Use of lowest possible setting Yes No Total	 11 (91.7%) 1 (8.3%) 12 (100)	 41 (62.1%) 25 (37.9%) 66 (100%)	 52 (66.7%) 26 (33.3%) 78 (100%) P = 0.046
Use collimator Yes No Total	 10 (83.3%) 2 (16.7%) 12 (100%)	 40 (60.6%) 26 (39.4%) 66 (100%)	 50 (64.1%) 28 (35.9%) 78 (100%) P = 0.131

In this study, knowledge of radiation protection positively affected the students' practice of taking dental radiographs with reduced exposure to radiation.[15] A higher proportion of students with good radiation protection knowledge use the lowest possible setting in acquiring dental radiographs which was at statistical significant level (P = 0.046). Similarly a higher proportion of these students with good knowledge of radiation protection kept a distance of more than 3 metres from the patients, wore lead aprons and used collimators (although not at statistical significant level). [16]About 86.4% of the students wore lead apron while all those with good knowledge did wear lead apron which sharply contrast with the 8.7% that did so in the study on dentists in Turkey.[19,20] Methods to protect the imaging health personnel include education, implementation of radiation protection program and usage of barrier shielding. The radiation protection program should also limit the life time and annual radiation exposure within the allowable threshold. Training in radiation protection should be a continuous process even after graduation from dental school because studies have shown that substantial amount of knowledge is lost by 6-12 months following course attendance, and to achieve long-term knowledge retention, early or repeated reinforcement

may be necessary.[16,21] Attendance at such refresher courses is crucial as about two-third of these students were aware that their knowledge of radiation protection was inadequate.

Conclusion

In conclusion, the dental students in this study did have good knowledge on radiation biology but show relatively poorer knowledge on radiation protection. Despite their poor radiation protection knowledge their practice was better. We recommend that the curriculum of dental school be expanded further to provide better exposure to radiation protection and its practice, so that these students on graduation will be well grounded with the principle governing dentalradiography, its justification, quality control practice and the correct practise of the ALARA concept.

Abstract

Introduction: For decades, black board has been the only way to teach school and college students in class but as years passed by, technology has been very efficient in bringing new electronic gadgets. Now with the new technologies, many colleges and schools have started using smart boards instead of blackboard. This study is being done to find out which is more efficient - black board or smart board, from the students of Saveetha dental college, Chennai.

Material and Methods: This research was done by interacting with 100 students from different batches and analysing which was - either smart board or black board, was more efficient and user- friendly.

Results:61% of the students preferred smart board and 39% preferred black board. 59% of students felt that smart board was more user friendly. 31% of the students felt that smart board was more complex when compared with black board

Conclusion: From this research, it will be evident which system is more approachable to the students and thus, it can be implemented in their respective schools and colleges.

Key Words*: Smart board; Black board; User-friendly; Efficiency; Animations*

Introduction

From earlier days, blackboard has been used in schools and colleges for teaching purposes.A blackboard or chalkboard is a reusable writing surface on which text or drawings are made with sticks of calcium sulphate or calcium carbonate, known, when used for this purpose, as chalk. Blackboards are manufactured by thin sheets of slate stones which is of black or dark colour. These blackboard are made in a way that these thin sheets are smooth as well.A blackboard can simply be a piece of board painted with dark paint (usually black or dark green). The marks made by the chalk can be easily cleaned off by using a wet cloth, a sponge or a duster which is made up of a blackboard eraser containing a wooden block covered by a pad to hold with hand. However, chalk marks made on some types of wet blackboard can be difficult to remove.

The smart board is starting to be used as a replacement for blackboards in many schools and colleges.The Smart Board interactive whiteboard operates as part of a system that includes the interactive whiteboard, a computer, a projector and white boarding software - either Smart Notebook collaborative learning software for education, or Smart Meeting Pro software for business. The components are connected wirelessly or via USB or serial cables. A projector connected to the computer displays the desktop image on the interactive whiteboard [1]. In this study, a questionnaire is prepared asking various questions regarding blackboard and smart board and the students are asked to fill it out to find out which is more approachable-either black board or smart board, and which system they prefer better.

There has been a constant shift in teaching methodologies for the students in various fields with the advent of technology. The innovative teaching has gained significant impetus as it is centred around better understanding in the student community and the teaching fraternity find it less cumbersome to the traditional methodologies. This study will be helpful in making changes accordingly in schools and colleges to make education and teaching more approachable and easier for students. The aim of this study is to compare the difference between black board and white board methodology of teaching and alsoto find out which system is better to approach to students so that it can be implemented in near future.

Materials and Methods

A set of questionnaires was prepared and given to 100 students of Saveetha dental college, Chennai. The questionnaire was on the topic smart board vs black board. The questionnaire

consisted of many questions whether the student preferred smart board or black board, if the student felt smart board was complex, if they understood black board drawings better or smart board animations better, if smart board has decreased the teacher's interaction with the students, which is not up tothe mark – black board or smart board, which is user-friendly: black board or smart board, if some information is cut out in smart board teaching. The questionnaire also listed questions asking about the advantages and disadvantages of both black board and smart board. From these questionnaires given to 100 students, the results can be analysed and the percentage will be more helpful for schools and colleges to understand which method of teaching reaches the student best and which should be set up in their respective schools and colleges.

Results

From the set of questionnaires answered by 100 students, 39% of students believed that black board was much better while the rest 61% of students preferred smart board as shown in the [Figure 1]. Just above half of the students who participated in the study (59%) felt that black board was more user-friendly since they have got more exposure to black board due to many years of usage as they have learned from it since their childhood times where the smart board is just at the beginning stage of emerging in schools and colleges. On the other hand, remaining 41% of students felt that smart board was more user-friendly than blackboard as illustrated in the [Figure 2]. 31% of students felt that the smart board technique was more complex and confusing to adapt whereas the rest 69% believed that it was much simple, convenient and is easy to access as illustrated in the [Figure 3].

On questioning the participants regarding the establishment of both methods of education, the black or white board system in accordance to their level of satisfaction or expectation, 35% of students admitted that they felt black board was not quite up to their expectations, while 45% of students felt that smart board was not up to their expectations. Whereas the rest 20% of students had a dilemma as they had little idea in distinguishing whether both the systems were good or not which is depicted in [Figure 4]. Now for the question about the use of colours while teaching, Seventy Seven out of hundred participants preferred colourful teaching while nineteenparticipants preferred conventional black and white teaching. The remaining four participants found comfort in both the methods.

Then the students were as asked about their preference of diagrams or animations for black board and white board respectively. 27% of students responded with their ability to understand with black board diagrams was better. On the other hand, 61% of students believed smart board animations were way more attractive and easier to remember when compared to black board diagrams. The rest 12% of students believed that both were helpful.

Discussion

This study was conducted among 100 dental students in order to assess the different teaching methodologies employing black board and smart board. It was conducted in the form of survey for evaluating the general pulse among the dental students towards the different teaching methods utilizing black board and smart board. Certain questions were included to gather knowledge about smart board teaching its merits and demerits. One of them is the information obtained by the students through smart board teaching. Regarding the amount of information delivered through smart board teaching, 46% of students believed that manyinformationis cut incase of smart board teaching whereas the rest 54% believed that enough information was provided in smart board and there were no cuts. A question was raised about the interactions among the teachers and students in classrooms during smartboard teaching. Total of 47 participants felt that there was less interaction between the teacher and students with smart boards teaching and rest 53 participants believed that there is enough interaction between the teacher and students using smart board similar to that of conventional method of teaching.

For the questions regarding the merits and demerits of both the system blackboard and white board, students responded about their views regarding both the system respectively. Considering the advantages of black board, most of the students said that it was user friendly and does not cost much for its set up and that black board was eco-friendlier. Whereas regarding its disadvantage, the students felt that it was more time consuming and it was lot of work to write on board and that it did not have colour images or animations. On the other hand, about the whiteboard, the students said that it can incorporate images and videos and can be viewed like it is real. When asked about the disadvantages of smart board, many said that it caused stress and strain to eyes and that it caused lot ofpower consumption and is complex to handle.

Dori and Kurtz et al checked to what degree the use of technological means contributes to understanding the study material and to students' motivation. Their research findings indicate that most students report that learning in a technological environment boosts their motivation and enhance their learning experience. The major contribution of technology as perceived by students is in increasing access to a variety of tools that contribute to understanding the study material, organization of the information, efficacy in carrying out assignments, and to development of knowledge [2].

The functions of smart board includedtouch feature where the mouse requires the touch to the surface of smart board or a screen. Apart from using the mouse, users are used to open and close documents with Windows applications, to be clicked web links, and also objects or pictures can be moved by finger swiping on the board [3, 4]. The feature of writing and deletion in smart board images and text to help existing users to write, draw and delete. Written text and images can be erased with a magnetic erase. It works like a hand eraser. In addition, the intelligent keyboard may be brought up on the board when needed [5, 6]. There is also drag and download feature that is suitable for any course that requires drawing, such as mathematics or engineering. These techniques are achieved by moving the stylus [7, 8].

One of the advantage of using smartboard technology is that users can record anyapplication seamlessly onto the board. These files which are recorded can be played again if required also on any computer. The files which are recorded can be played using Windows Media Player. Usersare able to save speeches and even their own voices, and areable to listen to them again. In addition, video files, whichwould play on all types of computers, can be created by users [9]. This creates ample time for the students to listen to the videos and also revise in the process of learning. This aids in student-centred

Many researches have been carried out to find out the use of smartboard to extend its limits. These researches have proven that educational advantage of use of smartboard for the students with special needs, it states that those types of students gain an opportunity study and obtain knowledge in a differentiated way which enables them to learn in a multi-sensory approach. This is a huge advantage to the students, particularly to those who have learning disability. The use of smartboard changes their disability to potentially able through increasing their attention, motivation to improve their learning process and also helps them to engage in the classroom activity [10].

Whiteboard has many merits and demerits. The merits are to keep students engaged, the teachers can create lessons which has incorporated videos, moving diagrams, animations and certain contents from online which helps in explaining difficult matters to students. This is possible by the use of interactive whiteboard. Whiteboard has a capability known as multimediawhere a teacher can explain an information in many possible different ways. This makes the lecture more interesting a lot more as it involves student participation [11]. For instance, if a teacher is teaching a lesson on some country like India, they can show the maps through Google Earth, making PowerPoints,regarding the country's population and certain histories and also an education video from YouTube regarding the wildlife present in India [12,13]. This makes the student to involuntary participate in topic discussion. As mentioned earlier, the students can participate in the classroom activity by writing on them, using certain objects as a part of activity session, playing games related to topic, or by voting an answer to the question by using handheld devices. These activities makes the students engaged and interested during lecture hours [14]. These boards helps teachers to show the students who had made projects by using PowerPoint software in order to motivate the student to participate and involve in learning process. Showcasing their projects helps the student enjoy their work as they take it as an appreciation when their work is displayed on a big screen in front of other classmates.

Regardless of the pros of whiteboards, their cost becomes a major concern. These boards are not cheap and there is an idea is that paying salary will the do the job of teaching rather than spending it on these boards [15]. Use of whiteboard depends upon the teacher's adaptation and use. Certain teachers like to stick to the traditional way of teaching using black boards preferably than adapting to the technology advancement. This makes the use of white board a major concern as the school may lose experienced teacher who has been in teaching conventional method due to sudden change in teaching methodology [16]. And also use of whiteboard requires some area of expertise in operating them to provide some knowledge to the students.

At last while teaching, the teachers does not like the students being distracted from listening to lecture for the sake of notes or important points of the topic [17]. Hence, the key points of the topic can be prepared in advance by the teacher by means of a PowerPointslide or other methods like chart, tables, maps etc., as it allows the students to pay attention to the lecture

by following the teacher and those points can be noted after the class hours during leisure time [18, 19]. This can be used as an alternative strategy for making the students actively participate in the learning process but cannot be used as a substitute for not attending the class lecture [20].

From the above data, it is evident that the students prefer smart board over black board. But both had equal advantages and disadvantages. A general consensus can be obtained from this study as it gauged the pulse of the students towards the different teaching methodologies whereas, a conclusion cannot be made because it is a survey with limited samples. It can be observed that while the smart board has lot of power consumption and is complex to use, black board consumes a lot of time and it cannot incorporate animations and colourful images. But when we look at the bright side, smart board has the ability to bring many images and animations virtually that is more helpful in understanding concepts. When it comes to black board, it is eco-friendlier and it helps the students to understand the diagrams better as the teachers will draw it in front of the students and in that way, the students will learn the technique to draw the diagram. So, if the institution is planning on setting up smart boards, the students will look forward for learning as the learning session will better with images and animations or if the institution is planning on setting up black boards, we can save lot of electricity and it will also be easy for the students to understand.

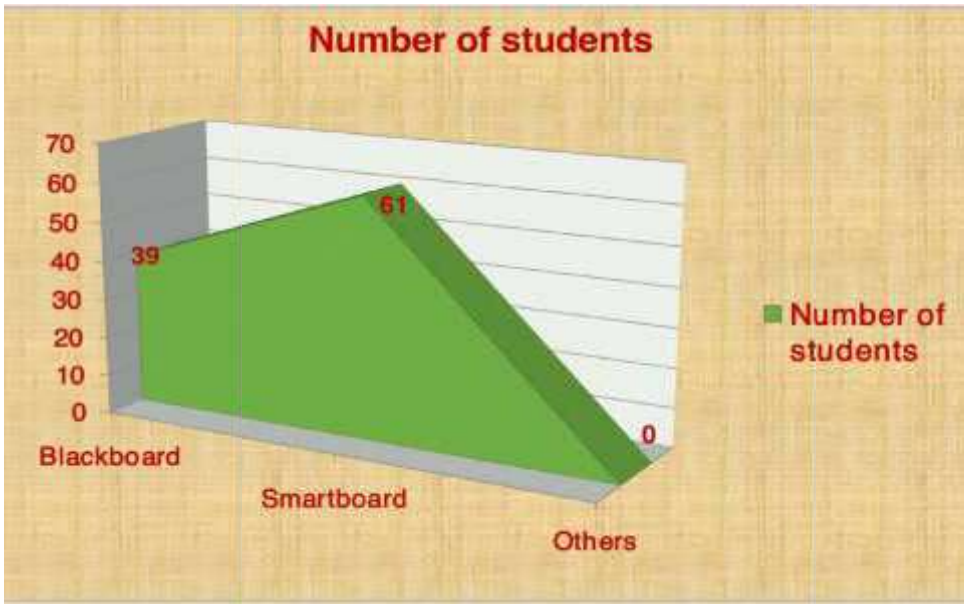

Figure 1: Percentage of students' preference for black board or smart board

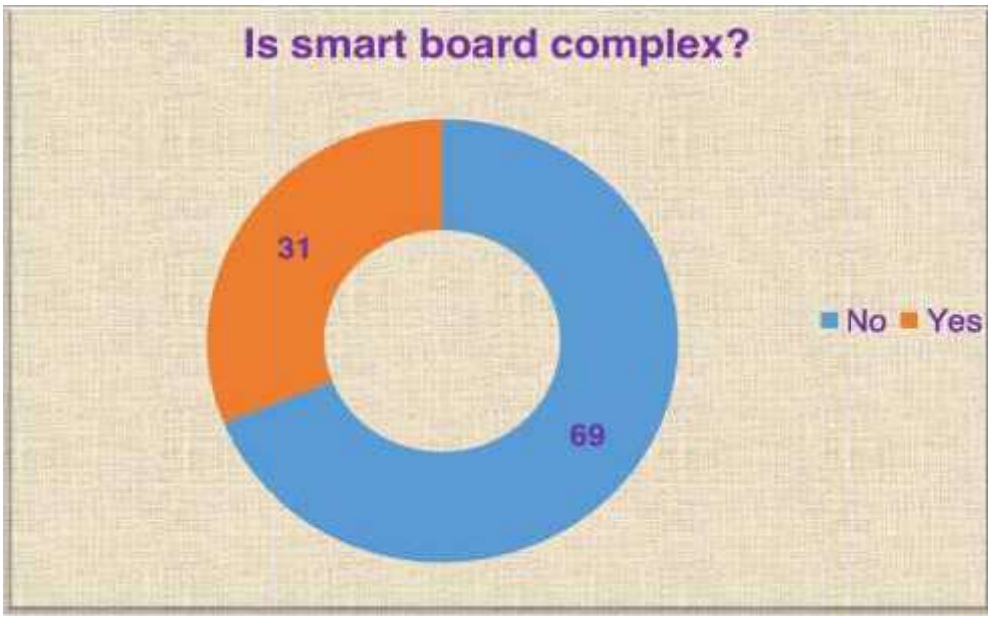

Figure 2: Percentage of students assessing the complexity of smart board

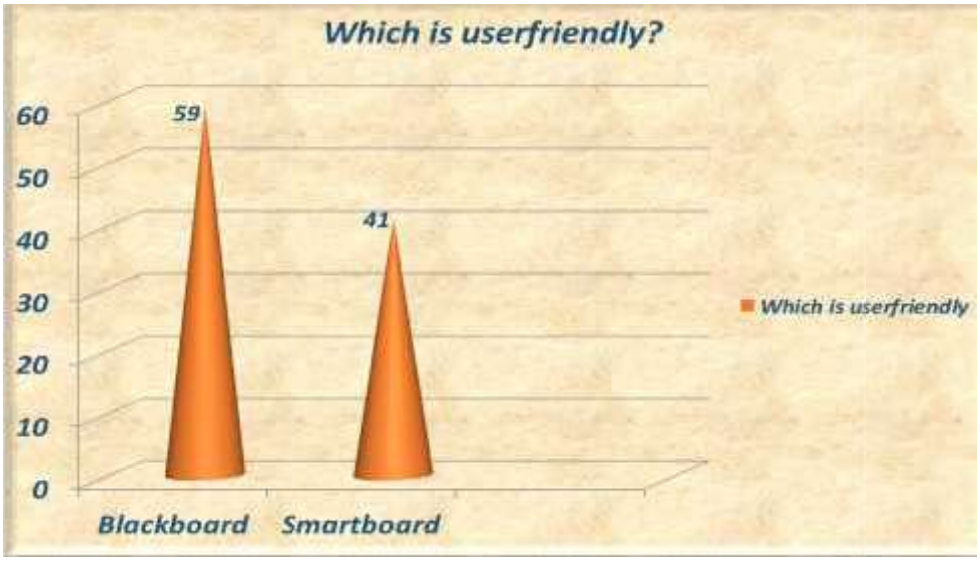

Figure 3: User-friendliness assessment of black board and smart board

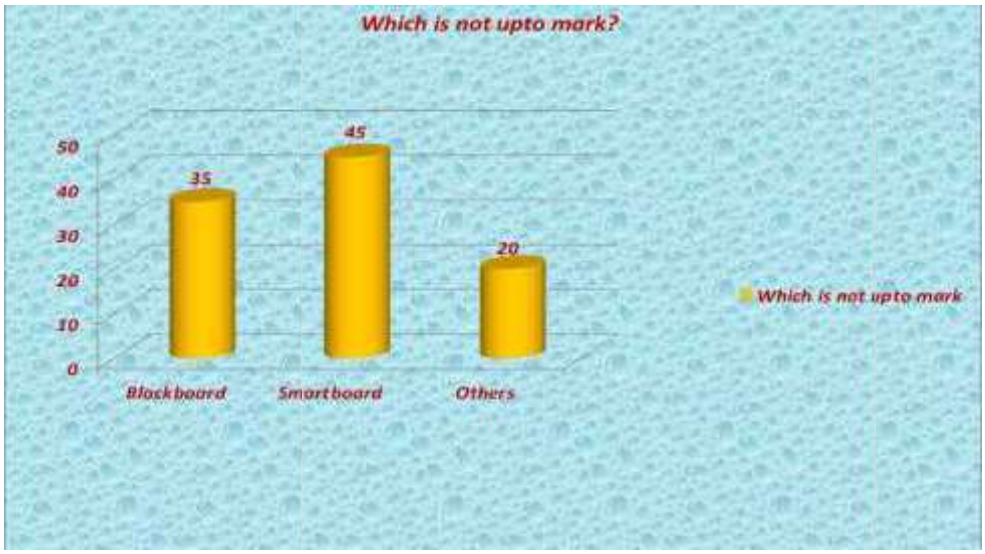

Figure 4: Percentage of student satisfaction using black board and smart board

Conclusion

Teachers play a major role as they influence the students towards the path of acquiring knowledge. Hence, a teacher should be aware in order to deliver the correct information through a technology so that it does not misguide the students. They should be comfortable and left to their own choice on selecting the method of teaching. If doubt arises, setting up both black board and smart board would be the finest option were the teaching can be done in smart boards while the diagrams can be taught using black board. By this way, teaching will be more approachable and efficient to the students.

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: Precision attachments are small interlocking devices to connect prosthesis and abutments that offer a variety of solutions to the challenge of balance between functional stability and cosmetic appeal. Precision attachments have wide applications, used in fixedremovable bridge, removable partial dentures, over dentures, implant retained over dentures, and maxillofacial prosthesis.

Materials and Methods: A closed ended questionnaire comprising 10 questions were prepared.

A total of 100 dental students were asked to complete the questionnaire. The completed questionnaire forms were collected personally. The data from the questionnaires were analyzed statistically.

Results: Out of 100 dental students,74% of the respondence were aware of precision attachment in FPD. 72% felt precision attachment improve chewing efficiency.63% expressed precision attachment is more expensive. 73% felt precision attachments offers better retention. 38% felt it repairs and modifications were easy with precision attachment and 71% opinioned precision attachments preserved the underlying hard and soft tissues.

Conclusion:Precision attachments present a challenge in the technical skill. A thorough understanding of the biomechanics of maxilla mandibular function, different attachments and knowledge, attitude and practiceis essential in treating a case of precision attachment in FPD.

Key Words:*Precision attachment, Fixed partial denture, Attitude, Implant and Over dentures.*

Introduction

A precision attachment is a precision-machined male and female (key and lock) housing that connects a removable partial denture to fixed bridgework. The female part of the attachment is soldered to fixed crowns , the male part is attached to the partial denture. The male is machined by the manufacturer to fit the female with such precision that any male out of the box will fit any female with an exact degree of accuracy. All of the precision attachments in a partial denture are positioned so that they are exactly parallel to each other.

Precision attachments in fixed partial dentures are the restorationswhere fixed restorations are contraindicated. There are many different kinds of attachments that will avoid the need for unsightly clasps, but only one type of precision attachment can claim has the greatest documentation when used according to basic principles of engineering. It was invented in 1906. When used properly, this type of precision attachment case will promote periodontal health and longevity of the abutments, prevent bone resorption of the ridges under the partial denture, and confer the highest degree of patient comfort.

An approach to eliminate the display of the clasp assembly with removable partial dentures is to consider the use of precisionor semi precision attachments. Precision attachments are generally poorly understood and overused in the profession.

Attachments have been classified as intracoronal or extracoronal and resilient or nonresilient, and each type of attachment has significant inherent associated deficiencies. With intracoronal attachments, room must be created for the attachment within the crown. This must be recognized at the time of tooth preparation and often results in removal of a considerable amount of sound tooth structure to accommodate the attachment. This loss of sound tooth structure represents a significant intervention into the structural integrity of the abutment tooth and exacts a biologic price that is often paid at a later date.

Extracoronal attachments by definition result in alteration ofthe physiologic crown contour of the abutment tooth and frequently establish a clinical situation in which it is extremely

difficult if not impossible for patients to maintain adequate oral hygiene beneath the attachment. This, again, usually exacts a biologic price, inthe form of periodontal disease or recurrent caries or both.

There are a large number of extra- coronal attachments available, and they vary considerably in their design and size. In general, it is the opinion of the authors that extra coronal attachments should be avoided with natural abutment teeth. If an extracoronal attachment is being considered for use, it is suggested that one of minimal size be chosen, to minimize the effect on physiologic crown contour, and that the patient be educated and encouraged to practice meticulous oral hygiene, to prevent the development of pathology. In general, resilient attachments are undesirable because they do not necessarily work in the manner in which they are intended, are usuallythe form of periodontal disease or recurrent caries or both.

There are a large number of extra- coronal attachments available, and they vary considerably in their design and size. In general, it is the opinion of the authors that extra- coronal attachments should be avoided with natural abutment teeth. If an extracoronal attachment is being considered for use, it is suggested that one of minimal size be chosen, to minimize the effect on physiologic crown contour, and that the patient be educated and encouraged to practice meticulous oral hygiene, to prevent the development of pathology.

The success of precision attachmentsin fixed partial dentures depends on creating an ideal architecture for the mouth. All the teeth that support bridgework are prepared with full shoulder preparations (flat ledges) in three-dimensions. In other words, the prepared teeth relate to each other, the gingiva and the underlying bone. Precision attachments must be used in a precise manner in order to maintain a high percentage of longevity. Great care must be taken to ensure precision at every step; and steps cannot be skipped or the final result will be compromised.

The entire chain can only be as strong as the weakest link. Precision attachment cases must fit with precision—the abutments must be stable and the frameworks must fit properly without rocking.Aim of the study is to assess the knowledge, attitude and practice regarding the use of precision attachments in fixed partial denture among the dental students.

Materials and Methods

The closed ended questionnaire approach was used to assess the Knowledge, attitude and practice regarding the use of precision attachments in fixed partial denture amongthe dental studentsin Dental college and hospital, Chennai. The questionnaire comprised 10 questions. A total of 100 dental students were asked to complete the questionnaire.(FIG – 1) The completed questionnaire forms were collected personally. The data from the questionnaires were analyzed statistically.

Results

Table 1: Responses to the questionnairein percentage (%)

QUESTIONS	YES(%)	NO(%)
1) Are you aware about the use of precision attachments in FPD ?	74% (74)	26% (26)
2) Do you think that the usage of precision attachments offers better chewing efficiency?	72% (72)	28% (28)
3) Do you think precision attachments are more expensive ?	63% (63)	37% (37)
4) Do you think that the caries occurrence rate is less with the use of precision attachments ?	58% (58)	42% (42)
5) Do you think precision attachments offers better retention ?	73% (73)	27% (27)

6) Do you think precision attachments provides better esthetics ?	74% (74)	26% (26)
7) Do you think the use of precision attachments offers a greater life span in FPD ?	41% (41)	59% (59)
8) Do you think precision attachments are easy to repair in FPD ?	38% (38)	62% (62)
9) Do you think the wear resistance is improved with the use of precision attachments ?	55% (55)	45% (45)
10) Do you think precision attachments preserve the hard and soft tissue ?	71% (71)	29% (29)

Discussion

In this study, the closed ended questionnaire approach was used to assess the knowledge, attitude and practice regarding the use of precision attachments in fixed partial denture among the undergraduate students in saveetha dental college and hospital, chennai. The questionnaire comprised 10 questions. A total of 100 dental students were asked to complete the questionnaire. The completed questionnaire forms were collected personally.

In which 74% of them were aware about the use of precision attachments in FPD and 26% were not aware about the use of precision attachments in FPD. 72% think that the usage of precision attachments offers better chewing efficiency and 38% don't think that the usage of precision attachments offers better chewing efficiency. 63% think precision attachments are more expensive and 37% don't think precision attachments are more expensive. 58% think that the caries occurrence rate is less with the use of precision attachments and 42% don't think that the caries occurrence rate is less with the use of precision attachments. 73% think precision attachments offers better retention.

27% don't think precision attachments offers better retention. 74% think precision attachments provides better esthetics and 26% don't think precision attachments provides better esthetics. 41% think the use of precision attachments offers a greater life span in FPD and 59% don't think the use of precision attachments offers a greater life span in FPD. 38% think precision attachments are easy to repair in FPD and 62% don't think precision attachments are easy to repair in FPD. 55% think the wear resistance is improved with the use of precision attachments and 45% don't think the wear resistance is improved with the use of precision attachments. 71% think precision attachments preserve the hard and soft tissue and 29% don't think precision attachments preserve the hard and soft tissue.(TABLE – 1)

Precision filled and semi precision attachments, improved impression materials, improved techniques and designs which would eventually attain a comprehensive treatment. In case of partially edentulous mouth, retention provided by the usage of precision attachments which may be related to comfort, satisfaction, chewing ability, as well as adequate distribution of occlusal loads to, and preservation of abutment teeth in patients with removable partial dentures. Retentive ability increases significantly over time in the metal- alloy precision attachments group.

There are many advantages of precision attachment. They are uncomplicated, precision-fitting, inter- changeable attachments. which are popular for RPD retention. Many technicians routinely stock these attachments and are familiar with their application. The labor cost is less than for laboratory made attachments (semi- precision attachment) because theyare prefabricated, and the retention is better. In addition, are placement that will fit exactly can be purchased andsoldered in place if breakage of an attachment occurs.Other attachments of similar design.such as the Stern Type 7 and the Stern G/A attachments.The technician must

not alter the configuration because the attachments are precision milled, therefore,the components of the attachment should not be air abraded or polished.

The milled guiding planes serve two purposes.They augment,the retention obtained from the attachments to help prevent undesirable attachment wear, and they guide the prosthesis during insertion and removal to facilitate handling. The combination of these guidingplanes and the parallel side attachments ensure rigidly fixed prosthesis with predictable retention that can also be easily removed and reinserted. Thus, the patient can clean the restoration daily although the prosthesis feels thesame as an FPD when seated in the mouth.

This fixed detachable prosthesis is versatile and can solve the problem of patient access for oral hygiene in most clinical situations.While the technique is especially usefulwhere there is extensive loss of residual bone and the softtissue must be replaced with the prosthesis, this attachment retained prosthesis analso beused when the implants were inadvertently inserted in lingo -version and the prosthesis is must be designed with facially placed artificial teeth. The patient may experience difficultiescleaning thetissue surface of a fixed prosthesis supported by lingually placed implants; however, this detachable design is a viable option to compensate for the unfavourable implant positions.

Charwaki HG et al(1) evaluated and quantified changes in retention ability and weight change over time and thus reported Metal-alloy and plastic inserts precision attachments preserve supporting teeth and alveolar bone ridges when associated with at least two splinted abutments.

Holst et al (2) cited as it is difficult to evaluate precision attachments' effects on treatment longevity based solely on *in vitro* results, since other factors such as continuous ridge resorption, changes in saliva flow and composition, and occlusal considerations may affect its long-term success. However, if an attachment removable partial denture is the treatment of choice because of esthetics, abutment alignment, or the need for greater cross-arch bracing, it must be used with a thorough knowledge and understanding of prosthodontic principles and attachment use, as well as an awareness of the intricacies and special problems associated with attachments.

The attachment is essentially a tube with a sleeve joint that provides bulk to the connector. For clinical cases where the extra coronal cast clasp displays the retention arm of a cast partial denture, the precision attachment of such types provide an alternative option for patients to be treated with a fixed partial denture(3,4).

In addition to clasps used to prevent the dislodgment of RPDs from the rest position during functional movements,(5) devices such as adhesive attachments, crowns, and FPDs with intra- or extracoronal attachments, telescopes, root-caps, and/or pre- fabricated intraradicular retainers may also be used to retain these prostheses. (6-9)

Most of the studies have shown that attachment retained cast partial dentures gives better comfort, function, esthetics ,less adjustments, protect abutment teeth, easy to clean and can worn most of the time by the patient. Its use in fixed prostheses, over dentures and in implant therapy contributes to the success of prosthesis in terms of esthetics, comfort and function(10).

Edentulism leads to an acknowledged impairment of oral function with both, aesthetic and psychological changes. Depending upon the clinical need and demand, restoration of the lost structure can be achieved by using conventional methods. (11) A full-arch fixed prosthesis can be fabricated, if sufficient and properly situated abutments remain orsufficient number of implants can be placed. However, both extensive fixed dental prosthesis and implant-supported prosthesis can be financially burdensome to patients (12,13).Retainer selection for removable dental prosthesis mainly depends on the remaining tooth structure, the intra- and inter-maxillary relationships, aesthetics, and financial aspects(14,15).

Preiskel first reported the inventions of attachments in early 20^{th} century. To the late 20^{th}century ,with growing technology the attachment has been applied to the superstructure of implant.

Nishimura et al (16) reported that the least stress was observed when using a nonrigid connector, and a rigid connector in particular situations caused slightly higher stresses in the supporting structure. The authors thought that limiting the stress would help protect the alveolar ridge from excessive load; that under certain occlusal forces, the resilience of the

attachment could be adjusted to distribute the force properly between the abutment and alveolar ridge.

Chou et al. (17) reported that a rigid-precision attachment produced great stresses and caused more movement of abutment teeth than did clasps, and they pointed out the risk of rigid-design dentures. However, the high stress, especially in apical areas, does not always cause damage to the tooth, because a tooth can withstand greater forces along the long axis than horizontal forces.

Kratochvil et al. (1981), Pezzoli et al. (1986) and Igarashi et al. (1999).(18,19,20) Reported that the frequency of relining of rigid-design denture was less. There was no significant difference between stresses on the denture bases of attachment dentures and telescopic dentures.

Feingold et al. (1988) (21) reported that the base movement of a rigid attachment was less than that of a resilient attachment. Saito et al. (1998) (22) investigated the vertical movements of modified clasp- and telescopic crown-retained denture, and they found that the displacement of the denture base decreased with an increase in the rigidity of the connection of the retainer to abutment teeth. However, the amount of displacement was influenced by the fulcrum line of rotation of the RPD.

The success of prosthesis depends on careful treatment planning and attention to the prosthodontic problems; the mechanical ingenuity of the attachment is important, but must take second place. Precision attachments present a challenge in the technical skill. A thorough understanding of the biomechanics of maxilla mandibular function, different attachments and knowledge of material science is essential in treating a case of precision attachment. Unfortunately, most often precision attachments are chosen from descriptions in manufacturer’s catalogues which leads to failure of precision attachment cases. Precision attachments serve the function of retention, stress distribution and aesthetics successfully provided the case is planned based on sound biological and technical grounds and proper care is rendered by the dentist and the patient during the maintenance phase. Hence precision

attachments should be employed for use in the fabrication of fixed prosthesis in the dental practice.

Conclusion

This study inferred the knowledge, awareness and practice regarding precision attachments in fixed prosthodontics is inadequate among the participants..This study alsohighlights the need for further awareness about the clinical applications of precision attachments in fixed – removable partial dentures among the undergraduate dental students in saveetha dental college, chennai.

Measuring Orthognathic Surgery Satisfaction in Orthodontic Patients- A Questionnaire Survey

Nandhini.S[1], Saravana Pandiyan[2], Mahathi.N[3]

Graduate Student[1], Reader[2], Department of Orthodontics, Reader[3], Department of Oral and Maxillofacial Surgery,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: In orthodontic surgical treatment the motivation of the patient for seeking treatment and her/his expectations of the results should be considered carefully in treatment planning. Therefore the patient satisfaction will be improved. The objective of this study was to develop a reliable self-report measure of consumer satisfaction with orthodontic treatment, and to preliminarily assess its validity. The aim of this study was to assess patients who have undergone orthognathic surgery.

Material and Method: A patient centered questionnaire to assess the satisfaction of the patients undergoing orthognathic surgery was being prepared and given to 50 patients in Saveetha dental college and the results are being discussed.This questionnaire is easily and quickly applicable and economic, however, it should be kept in mind that it is subjective.

Results: 50 participants who attended the O.P of Department of orthodontics, Saveetha Dental college, were included in the study. When questions were asked about their experience in the department, 98% felt the treatment was hygienic, 96% felt the treatment was expensive 86% felt they were well informed. And only 62% had discomfort during the treatment. when asked about treatment outcomes, 97% had a smile satisfaction, 95% said they would recommend to friends. 88% felt they had experienced pain. Finally questions were asked about how it affects the quality of life of the patients.

Conclusion: In conclusion, orthognathic surgery causes significant improvement in patients' quality of life. This improvement was seen in emotional, oral function, psychological, and social domains of quality of life. The maximum influence was in emotional and the least in

functional aspect. Our study assessed quality of life in a limited period postoperatively and obviously there is a need for longitudinal studies in this area of healthcare services.

***Key Words**: Orthognathic surgery, satisfaction, smile, confidence, measurement.*

Introduction

Orthodontists, like other health care professionals, rely on patient cooperation for successful treatment outcomes, and an important factor in this success is patient's satisfaction with the delivery of care [1].Patient satisfaction after orthodontic treatment isinfluenced by a number of factors. To illustrate,psychological traits of individual patients affect theirsatisfaction with orthodontic treatment outcomes.Factors like gender, age, duration of treatment,compliance, and dentofacial improvement also seemto contribute to the level of satisfaction.Patientsatisfaction is important for ensuring patient adherencein orthodontic treatment. In previous studies, differentfactors have been explored and different instrumentshave been used to assess satisfaction after orthodontic treatment. Not surprisingly, investigations of patientsatisfaction after orthodontic treatment have shown awide range of satisfaction levels.Thismakescomparisons between studies difficult.Almost a decade ago, in a study in the Netherlands,the patient satisfaction questionnaire developed by Boset al.

The factors like doctor-patient relationship, situational aspects, dento-facial improvement, psychosocial improvement, anddental function, as well as a residual category, wereexplored. It was shown that the most important factorcontributing to patient satisfaction was the patient'ssatisfaction with the doctor-patient relationship.Gender was shown to be a significant predictor of thepatient's satisfaction with the doctor-patient relationshipand the situational aspects of the treatment.However, dental attitudes of patients have changedover time.Over the past decade, the number ofpatients seeking orthodontic treatment has increasedconsiderably with socioeconomic development andchanging opinions on appearance.[2,3,4]

Orthodontic tooth movement (OTM) is mainly a biological response towards mechanical force .Skeletal disfigurement of the face has a negative effect on many aspects of life. These include social interactions, opportunities, choice of profession, choice of partner, and personality characteristics. Subjects with malocclusion, particularly those in need of surgical

corrections, have a lower health-related quality-of-life and are more anxious .It therefore seems reasonable to offer orthognathic surgery as appropriate treatment to correct a disfigurement if it is subjectively perceived as a handicap, in part to improve the psychology of the patient. This leads to the consideration that patients' perception of the quality of orthognathic surgery is dependent upon several factors. These are not only aesthetics and function, but also psychological aspects. As a consequence, patients' preoperative expectations of orthognathic surgery and postoperative outcome could offer discrepancies if patients are not clearly informed of what is possible and what is not.However, without patient cooperation, few medical or dental therapies, including orthodontics, will achieve optimum results.It has been shown that a desire for orthodontic treatment, together with a sound understanding by the patient of the nature of the malocclusion, auger well for future compliance.Hence, compliance does not remain the sole responsibility of the patient.

Rather, orthodontists need to inform and instruct their patients to such a level as to ensure their full commitment. It is of concern that patients show a very low recall rate with regard to any risks associated with orthodontic treatment. Lack of communication between the orthodontist and the patient and insufficient information about orthodontics can lead to premature termination of the treatment. Orthodontists should therefore look at the way theyeducate patients, ensuring that full comprehension has been achieved. Measuring treatment satisfaction is a complex task.Patient satisfaction is higher when visible treatment outcome goals are met and when their expectancy with regard to psychosocial benefits is lower. The key to success is to discover the actions that will produce the most positive response from the patient. Orthodontists should strive to achieve the correct bite and an excellent smile, but they have not been truly successful if their patients have not also benefitted psychosocially.The fulfillment of patient expectations has become one of the main objectives of health care systems.[5,6]

Patients' expression of desires is important because health professionals often underestimate them for care. The clinician with an awareness of a patient's demands is better able to satisfy the patient's justified desires and to initiate frank discussion about those expectations that are unrealistic, leading to more productive clinical negotiations.Assessment of patients' expectations is central to understanding oral health needs, patient satisfaction with treatment, and ultimately the perceived overall quality of health systems.Mismatch between patient

desires and the service received is relatedto decreased satisfaction.Patient satisfaction is a multifaceteddimension; however, people may have a complexset of important and relevant beliefs.Interest in-patient satisfaction with various aspects of their healthcare has grown significantly for surgeons and orthodontists. The benefits provided by a combined orthodontic-surgical treatment,as well as the potentialrisks and negative side effects regarding this therapy.[7,8,9]

Orthodontists and oral maxillofacial surgeons shouldthe informed consent process and properlytemper patients' expectations by limiting false impressions of a "new face" after such complex treatment.Ithas been observed that patients tend to expect theirnew profile to fit more closely to socially acceptedpatterns than what should really be expected.Another major factor to be considered is that theperceived care and attention the orthodontist, surgeon,and staff provided to the patient increased the patient'sconfidence in the orthodontic/surgical treatment out-comes. However, perception of care is a broadcategory that was sometimes only assessed as qualityof care in the studies examined.The overall aim of orthodontic care should be good treatment results and satisfied patients but at a reasonable cost. To reach this goal it is important that the quality of care is continuously and systematically evaluated and documented by means of professional clinical assessmentsand patient questionnaires or interviews.Patients with inappropriately high expectations may be dissatisfied with the optimal care and those with inappropriately low expectations may be satisfied with deficient care.From a policy perspective, understanding patients' concerns and requests is important for the measurement of health care quality, the delivery of health services, and the costs of care.Correlations between satisfaction with dental and facial appearance and expectations of orthodontic treatment appear to be age but not gender related.[10,11]

The aim of this study was to assess patients.Orthodontists should recognize and respond to these needs, for as caring professionals they may be the patient's only source of positive reinforcement.

The main goals of orthodontic treatment are to correct aesthetic impairment, improve oral function, and help patients restore their socio psychological well-being A number of factors may influence patient satisfaction, including physical comfort, emotional support, patients expectations, and respect for patient preference.This research is being designed to measure the satisfaction of orthodontic patients undergoing orthodontic surgery.[12]

Materials and Methods

A patient-centered questionnaire to assess satisfaction of the patients undergoing orthognathic surgery was being prepared and given to 50 patients in Saveetha dental college and the results are being discussed.

Inclusion criteria -This questionnaire was distributed only to patients who have undergone orthognathic surgery.

This questionnaire is easily and quickly applicable and economic, however, it should be kept in mind that it is subjective because replies can be effected by patients' moods at the time of quastionnaire.The questionnaire is as follows:

Table 1: Questionnaire

1-Was the treatment hygienic and sanitary?
2- Do you feel like it's an expensive treatment?
3-Did the doctor keep you informed about the procedure?
4-Do you feel orthognathic surgery along with the orthodontic treatment takes a longer time?
5- Did you feel any discomfort in this long term treatment?
6-Did you have pain during the treatment?
7-Considering everything, do you feel the orthognathic treatment increases your self-confidence?
8-Do you feel treatment has improved your chewing ability?
9-Do you feel treatment has improved your speech quality?
10-Are you satisfied with the alignment of your teeth?
11-Are you satisfied with your final facial appearance?
12-Are you satisfied with your smile?
13-Are you satisfied with the overall results of the treatment?
14- Do you feel this orthodontic treatment along with orthognathic surgery is useful?
15- Would you recommend your family, relatives and friends to go through the same kind of treatment?

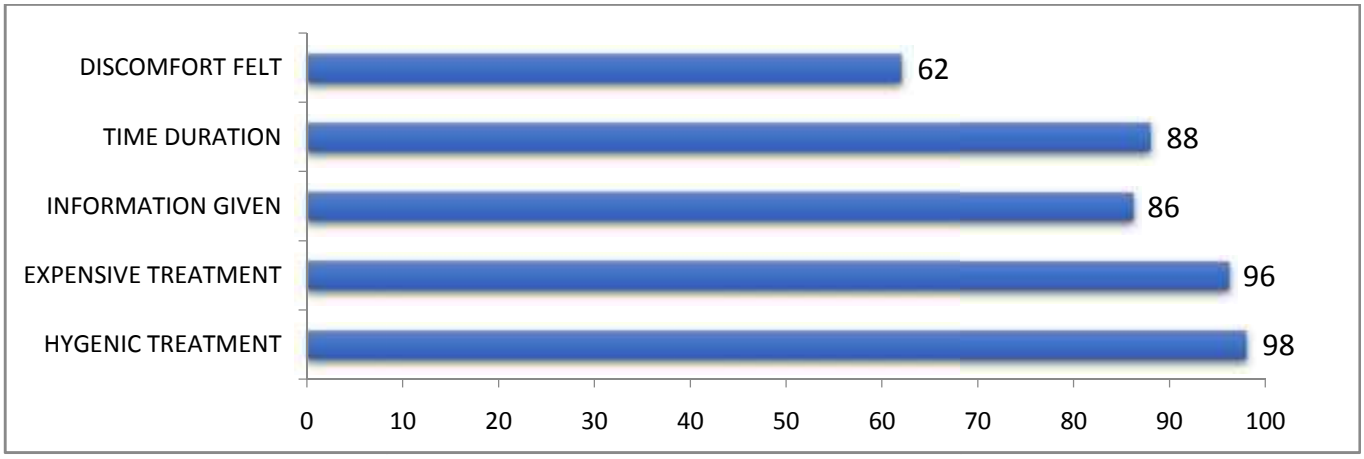
Results

50 participants who attended the O.P of Department of orthodontics, Saveetha Dental college, were included in the study. When questions were asked about their experience in the

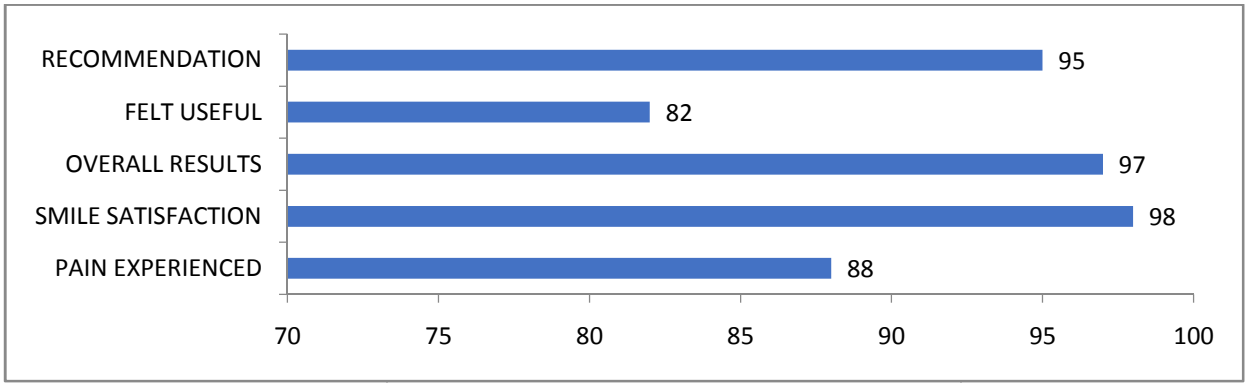
department, 98% felt the treatment was hygienic, 96% felt the treatment was expensive 86% felt they were well informed. And only 62% had discomfort during the treatment (Graph I).

when asked about treatment outcomes, 97% had a smile satisfaction, 95% said they would recommend to friends. 88% felt they had experienced pain (Graph II). Finally questions were asked about how it affects the quality of life of the patients, and the outcomes are listed in Graph III.

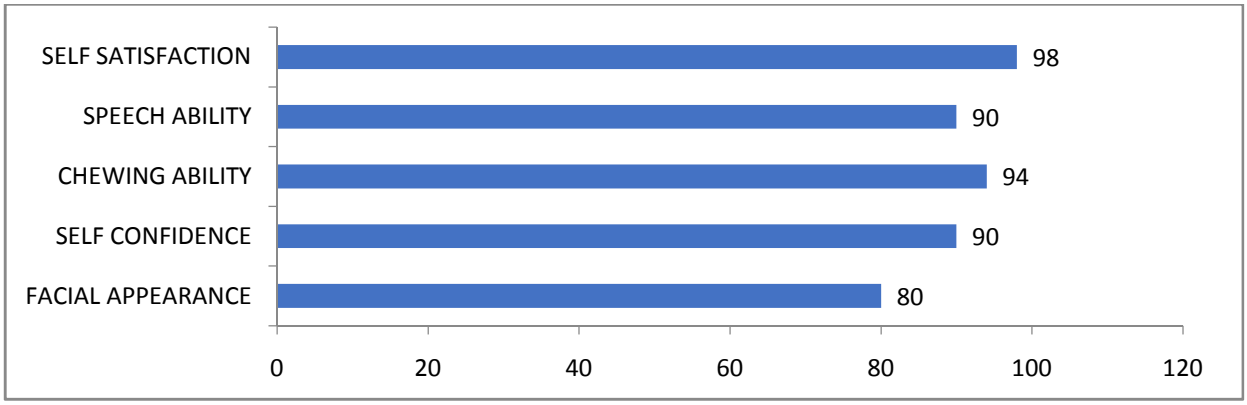
Graph 1: Factors experienced by patients regarding orthognathic treatment



Graph 2: Patients experience regarding treatment outcome



Graph 3: Improvement in patients quality of life post orthognathic therapy



Discussion

Patient satisfaction with orthodontic treatment hasno definitive outcome in the literature.This can beexplained by the different motivations and expectations of patients receiving orthodontic treatment. Moststudies report functional, esthetic, and social reasons as the main motives to seek orthodontic treatment.Satisfaction level may be affected by the severity of themalocclusion at the beginning of the treatment or bythe final result of the treatment. However, a recentstudy showed that patient satisfaction is not necessarily bound to the severity of malocclusion beforetreatment or the final result of the treatment.Thecurrent status of the dentition may be more relevant forpatients than the benefits obtained just after orthodontic treatment.Dentofacial deformities drastically affect patient's health related qualities of life. Especially unaesthetic appereances of soft tissue and skeletal architecture in class 3 deformities may cause psychological problems.[13,14]

Therefore, the most crucial step of preoperative planning in orthognathic surgery candidates is psychological assessment. Ideally, a psychiatrist or psychologist should undertake this assesment. If this cannot be provided, an orthodontist or surgeon should evaluate the patient carefully. Patient's self-perception of facial appearance can differ from physicians perception. Therefore, patient's subjective complaints and expectations should be analyzed carefully. [15]

Physicians should decide whether they can meet these expectations .Studies show that even if there are minor disparities in the results, patients are satisfied with the results of orthognathic surgeries. There are many factors that might cause postoperative dissatisfaction. Most of them are secondary to miscommunication of patient and physician rather than poor postoperative results or lack of surgical skills.Many measurement indexes are used for assessing the benefits of orthognathic surgery and usually questionnaires are preferred. The questionnaire was assessed for the satisfaction of the patients.50 Orthognathic patients

completed the questionnaire. And 98% of them feel that the treatment is hygienic and sanitary.So it is understood that the treatment is a better one. But 96% of them feel it is an expensive treatment.86% of the doctors kept the patients well informed about this procedure and 62% of them feels discomfort and major percentage of them that is nearly 80% feels that it is an expensive procedure.94% patients have reported that it improves their chewing ability and expect few everyone are happy about the smile and facial appearance. Nearly 98% of patients are satisfies with speech quality and the teeth alignment and nearly 96% of people are satisfies with this procedure.94% patients would like to recommend it to their friends, relatives and family.This study has several limitations. More patients with longer follow-up and a survey before the institution of orthodontics would be useful to better correlate the results with lasting benefits obtained through orthognathic surgery.

Conclusion

In conclusion, orthognathic surgery causes significant improvement in patients' quality of life. This improvement was seen in emotional, oral function, psychological, and social domains of quality of life. The maximum influence was in emotional and the least in functional aspect. Our study assessed quality of life in a limited period postoperatively and obviously there is a need for longitudinal studies in this area of healthcare services.This report focuses on patient satisfaction with orthognathic treatment as an outcome measure of the quality of the treatment. Based on the results, it is very well clear that almost 94% of the patients are satisfied with this treatment, inspite of the discomfort.There are many studies which proves the quality and success rate of the orthognathic treatment. Though it is expensive, the effectiveness of the treatment overcomes it. This survey reveals the existing scenario of orthognathic practice and highlights the importance of it.

Abstract

IntroductionAll the people donot possess all these characters at a same degree. The higher the degree , the better mental health. They are independent and responsible and also is giving and productive. The lower the degree they are depressed and are under mental stress. This survey was conducted to assess the mental health of individuals.

Aim and objective : To assess the mental health status of individuals of Saveetha University.

Materials and Methods:A survey based on mental health questionnaire by Augustes was used to evaluate the mental health of individuals.. A total of 50 individuals studying I BDS from a Reputed college were selected. They were made to sit comfortably and were given the questionnaire to fill . Once done , the results were collected and tabulated

Results: Mental health is a condition of psychological maturity a relatively constant and the enduring function of personality. It is the adjustment of human beings to the world and to each other with a maximum of effectiveness and happiness.This study concludes that individuals differ in their mental health values.

Key Words: *Social behaviour, personality, emotion, psychological maturity, socially well being.*

Introduction

According to Menninger, mental health refers to "the adjustment of human beings to the world and to each other with a maximum of effectiveness and happiness. It is the ability to maintain an even temper , an alert intelligence , socially considerate behaviour and a happy disposition". Mental health is a state of physiological maturity–a relatively constant and enduring function of personality [1]. According to the World Health Organization, mental health includes "subjective well-being, perceived self-efficacy, autonomy, competence, inter-generational dependence, and self-actualization of one's intellectual and emotional potential, among others [2].

Mental health is important at every stages of life, from childhood and adolescence toadulthood .

In general there are five primary senses to attain satisfaction and social adjustment.

1. A sense of responsibility: it is an awareness of what consequences he / she will dues to their behaviour and its effect on others
2. A sense of self – reliance a confidence of one's own way of facing problems rather than to display anger or anyother emotional outbursts.
3. A sense of direction – setting good goals and directing efforts towards success.
4. A set of personal values –having a philosophy about life based on their own beliefs and goals. The philosophy of life will tend to increase their social status.
5. A sense of individuality –recognising oneself from others. The person endeavours to develop attitudes and patterns of behaviour that entail neither blind conformityto the desires and demands of others nor a rebellious detachment and isolation from others.

All the people donot possess all these characters at a same degree. The higher the degree , the better mental health. They are independent and responsible and also is giving and productive. The lower the degree they are depressed and are under mental stress. They require motivation and counselling [3].

Particularly students in late adolescence are introduced to professional course with very minimal or no mental preparation is bound to cause a lotof adjustment, personality, behaviour, anxiety and depression among students. They also undergo a lotf of physical and

hormonal changes being a teenager. Social changes like being away from home, stressful and demanding work schedule, excessive competition etc [4-7].

Also, the changing global demographic, Economical, cultural, political, educational scenarios has created a lot of mental stressto students thus making assessment of mental health status and providing care and support is a need of the hour for a better and healthy society [8].

Materials and Methods

A survey based questionnaire was used to evaluate the mental health of individuals. It was carried out in the month of November 2015. A total of 50 individuals studying I BDS from a reputed dental college were selected. They were made to sit comfortably and were given the questionnaire to fill . Once done , the results were collected and tabulated.

The questionnaire is as follows:

I. How happy, satisfied or pleased have you been with your personal life during the past month.?

1. Extremely happy, could not be more pleased or satisfied
2. Very happy most of the time.
3. Generally, satisfied,pleased.
4. sometimes fairly satisfied, sometimes fairly unhappy
5. generallydissatidfied, unhappy
6. verydissatisfied,unhappy most of the time

II.How much of the time have you felt lonely during the past month?

1. None of the time
2. a little of the time
3. some of the time
4. a good bit of the time
5. most of the time
6. all the time

III.How often did you become nervous or jumpy when faced with excitement or unexpected situations during the past month?

1. Always

2. Very often
3. Fairly often
4. Sometimes
5. Almost never
6. Never

IV.During the past month, how much time have you felt that the future looks hopeful and promising?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

V.How much time, during the past month, has your daily life been full of things that were interesting to you?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

VI.How much time, during the past month, did you feel relaxed and free from tension?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

VII.During the past month, how much of the time have you generally enjoyed the things you do?

1.All the time

2.Most of the time

3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

VIII.During the past month, have you had any reason to wonder if you were losing your mind or losing control over the way you act, talk, think, feel or any of your memory?

1. Yes, I am very much concerned about it
2. Yes, I am quite concerned about it
3. Yes, and I have been a little concerned
4. Yes, but not enough to be concerned or worried about it
5. May be a little
6. Not at all

IX.Did you feel depressed during the last month?

1.No, never felt depressed at all

2.Yes, a little depressed now and then

3.yes, quite depressed several times

4.yes, very depressed almost all the time

5. yes to the point that Ididnot care about anything for days at a time

X.During the past month, how much time have you felt loved and wanted?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XI.How much time, during the past month, have you been a very nervous person.?

1. All the time

2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XII.When have you got up in the morning, this past month, about how often did you expect o have an interesting day?

1. Always
2. Very often
3. Fairly often
4. Sometimes
5. Almost never
6. Never

XIII.During the past month, how muchof the time have you felt tense or “high strung “?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XIV. During the past month, how often did your hands shake when you tried to do something?

1. Always
2. Very often
3. Fairly often
4. Sometimes
5. Almost never
6. Never

XV. During the past month, how often did you feel that you had nothing to look forward to?

1. Always
2. Very often
3. Fairly often
4. Sometimes
5. Almost never
6. Never

XVI. How much of the time, during the past month, have you felt calm and peaceful?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XVII. How much of the time, during the past month, have you felt emotionally stable?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XVIII. How much of the time, during the past month. Have you felt downheartened and blue?

1. All the time
2. Most of the time
3. A good bit of the time
4. Some of the time
5. A little of the time
6. None of the time

XIX. How often have you felt like crying, during the past month?

1.All the time

2.Most of the time

3.A good bit of the time

4.Some of the time

5.A little of the time

6.None of the time

XX. During the past month, how often have you felt that others would be better off if you were dead?

1. Always
2. Very often
3. Fairly often
4. Sometimes
5. Almost never
6. Never

Results

The scores were calculated as per the options and the scores were tabulated as below 40, 40 to 80 and above 80.

Table 1:Shows the scores of individuals that are tabulated in ranges from 0-40, between 40-80 and 81-120

S.No	**Low 0 - 40**	**In between 40 - 80**	**High 81 - 120**
1.	34	55	89
2.	22	43	93
3.	27	67	99
4.	33	66	103
5.	39	74	107
6.	29	56	100
7.	25	71	82
8.	30	60	97
9.	24	50	110
10.	37	55	105

11.	35	73	88
12.	28	68	108
13.		67	90
14.		45	
15.		72	
16.		61	
17.		70	
18.		48	
19.		51	
20.		49	
21.		68	
22.		43	
23.		73	
24.		78	
25.		42	
Average	30.25	60.2	97.76

Table 2:Shows the lowest value and highest value of each categoriesrr

S. No	**Low 0 - 40**	**Inbetween 40 - 80**	**High 81 – 120**
Lowest value	22	42	82
Highest value	39	78	110

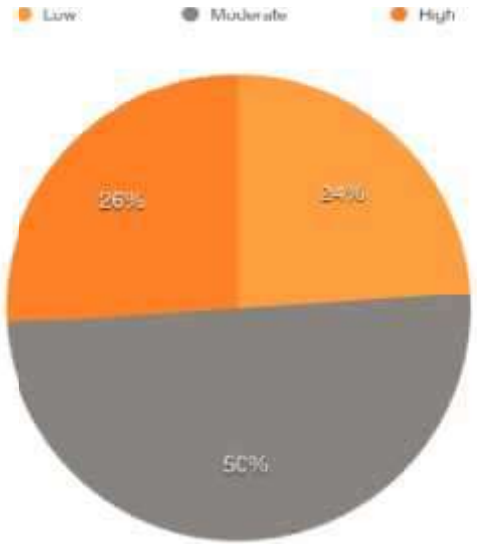

Figure 1:Showspie chart of the scores categorised as low, moderate and high

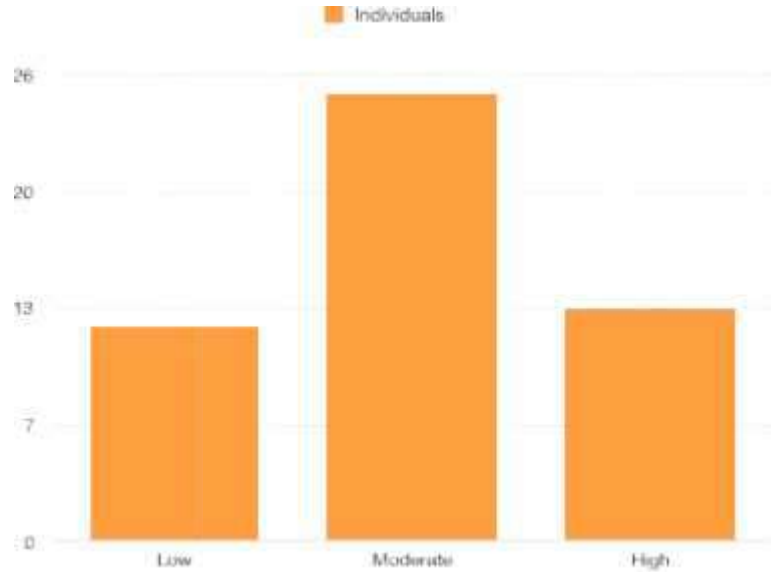

Figure 2:Shows the bar graph the scores categorised as low, moderate and high.

Discussion

Stress is the basic reason for any psychological issue. Many factors determine the healthy mental status, say from peer pressure , family , academics , society and socioeconomic status. Physical health also contributes to mental health to progress positively. This study

throws vision upon creativity and awareness among counsellors to give notice upon the mental well being and f the individual. This can help them to guide the individuals to improve, modify or to have a balanced mental health, according to the values scored by them [9].

A total of about 50 individuals were assessed. Among that , the mental health of 12 people was low with an average of 30.25. The highest value is 39 and the lowest value is 22. The mental health of 13 people were extremely high with an average of 97.76. The highest value in this group is 110 and the lowest value is 82. The mental health of 27 people were moderate and the average value is 60.89. The highest value is 78 and the lowest value is 42. Thus, mental health varies among the individuals of the university .

Several studies have been conducted in different parts of the world like Pakistan and USA. Similar study conducted by Sherina MS et-al from Malaysia, the prevalence of depression was33.6% using the CES-D scale [10]. Another study conducted by Rael D Strous et al found 55.5% of the students had reported poor mental health status [11]. In a study conducted by shah Navas P and Dahlin M et al revealed that the prevalence was as low as 23% and 12% respectively [12,13].Various international studies conducted in different parts of world like Pakistan and United States of America reported the prevalence of depression to be 15- 65% among medical students [15,16]

Mental illnesses are serious disorders which can affect your thinking, mood and behaviour. There are many causes of mental disorders. The genes and family history of individuals play an important role. Several life experiences such as stress or history of abuse also matter to a greater extent. Biological factors can also be a part of the cause. Hence mental disorders are common among these people. Treatment and therapies are available for these disorders that include Meditation, Relaxation, Yoga For Health etc [17-20]

Conclusion

Mental health is a condition of psychological maturity a relatively constant and the enduring function of personality. It is the adjustment of human beings to the world and to each other with a maximum of effectiveness and happiness. It is the ability to maintain an even temper, an alert intelligence, socially considerate behaviour and a happy disposition. I am interested to analyse the different levels of maturity of various individuals and also interested to help in

improving their maturity levels.This study also concludes that individuals differ in their mental health values.

Parents Attitude and Knowledge towards Dental Radiography in Children

Priyadharshni S[1], Shantha Rajan[2], E. Roja[3]
Graduate Student[1], Senior Lecturer[2], Department of Pedodontics,Tutor[3], Department of Public Health Dentistry,
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction:Radiographs are an essential part of most clinical dental examinations and diagnoses. Radiographs often add critical information to the clinical examination revealing developmental and eruption problem in addition to caries, pulp, and peri apical pathology. Radio graphic guidelines exist to avoid unnecessary exposure,as well as to identify individuals for whom radiographic examination will be beneficial.It is unknown whether radiation fears are exaggerated or whether parents recognise and accept the associated risks.The aim of this study is to determine the parental knowledge and attitude towards dental radiography in children.

Material and Method: A self-administered questionnaire is prepared and distributed to 42 parents with children who are to be radiographed in Chennai population and covering parental level of radiation and socio-demographics was applied which is used to assess attitude towards dental radiographs.

Results: 65% parents have a positive attitude towards dental radiographs on their children. However, the majority of parents lack knowledge(20%) regarding dental radiography, especially regarding the risks involved.

Conclusion: Most parents had a positive attitude towards dental radiographs although they had limited knowledge about radiography. This study emphasises the importance of providing accurate and appropriate information so patients and parents have a better knowledge and understanding of dental radiographs.

Key Words*: Radiograph, children, radiation, knowledge, health.*

Introduction

Professor Wilhelm Conrad Roentgen, a Bavarian physicist, accidentally discovered X-rays on November 8, 1895. The first dental bitewing radiograph, whose exposure time was about 25 minutes due to combination of unreliable generator output and relatively low sensitivity of receptor, was performed on himself by Dr. Otto Walkhoff in 1896, which was glass plated it by hand with photographic silver emulsion [1]. This cumulative effect of long and repetitive radiation exposure led to the irreparably damaged tissues of the radiography's early pioneers [2], this raised an issue to decrease the radiation exposure to the public and the operator. As a result the radiation doses have been greatly reduced needed to make radiographic images over the past century [1]. Today various factors such as fast lm, collimation, filtration, standardisation of x-ray lm processing, have greatly helped us in quality assurance programmes and achieving a reasonable radiographs by keeping radiation hazards at bay [2]. As technology advances in dental radiology, operators must maintain current knowledge and adapt their skills for the best treatment of the patient. Radiography is a highly technical held, essential to the modern dental practice. The intraoral radiographic image, when correlated with the case history and clinical examination, is one of the most useful and powerful diagnostic aids available to the dental practitioner. Although the radiation doses used by dentists might be low for individual examinations, patients are exposed to repeated examinations overtime, and many people are exposed during the course of dental care [3]. Broad range of exposures used in dental offices ranging from 5 μSv bitewing to 14-24 μSv for extra-oral imaging such as panoramic radiography are encountered. Thanks to such varied techniques, per capita dose of radiation has increased in today’s population, nonetheless our awareness regarding the same has also increased [4]. Hence the major concern of dentist is to reduce the radiation exposure to the patient and surrounding environment, without compromising the quality of image [4]. Therefore proper techniques must be employed to reduce radiation exposure to the patient through the use of protective aprons, digital radiology, high speed lms, and proper technique; thus decreasing radiographic retakes and additional exposure.

Due to the faith entrusted by the parents on the dentists regarding their children’s care, it is the moral responsibility of the dentist to inform about the biohazards associated with radiation to the parents. Children are more vulnerable to radiation than adults, which is due to the fact that there is a longer life expectancy and thus a greater potential for radiation-induced

cancers to manifest. Furthermore, the cumulative nature of radiation exposure over a patient's lifetime increases the importance of explaining radiation risks to parents[5].

Dental radiographs play an important role in the detection and management of oral diseases and a useful diagnostic aid in oral examination of children. While radiation exposure in the dental setting is relatively low, it is one of the most frequently undertaken radiographic procedures, and is often repeated several times during childhood and adolescence. When visiting the dentist, parents entrust the dentist with the care of their children and therefore they have the right to understand the often complex risks and benefits of a procedure, including the taking of radiographs.Radiographs often add critical information to the clinical examination, revealing developmental and eruption problems in addition to caries, pulp and periapical pathology. Radiographic guidelines exist to avoid unnecessary exposure, as well as to identify individuals for whom radiographic examination will be beneficial[6].

Radiographs should be taken only when there is an expectation that the diagnostic yield will affect patient care. The AAPD recognises that there may be clinical circumstances for which a radiograph is indicated, but a diagnostic image cannot be obtained. For example, the patient may be unable to cooperate or the dentist may have privileges in a health care facility lacking intraoral radiographic capabilities. If radiographs of diagnostic quality are unobtainable, the dentist should confer with the parent to determine appropriate management techniques (eg, preventive/restorative interventions, advanced behaviourguidance modalities, deferral, referral), giving consideration to the relative risks and benefits of the various treatment options for the patient.Because the effects of radiation exposure accumulate over time, every effort must be made to minimise the patient's exposure. Good radiological practices (eg, use of lead apron, thyroid collars, and high-speed film; beam collimation) are important. The dentist must weigh the benefits of obtaining radiographs against the patient's risk of radiation exposure.Dental X-rays are very safe and expose your child to a minimal amount of radiation. When all standard safety precautions are taken, today's X-ray equipment is able to prevent unnecessary radiation and allows the dentist to focus the X-ray beam on a specific part of the mouth. High-speed film enables the dentist to reduce the amount of radiation the patient receives. A lead body apron or shield will be placed over the child's body. Make sure the shield covers your child's neck to protect the thyroid gland.Keywords for good practice are appropriate selection criteria for the use of radiography, optimised radiation protection and

utilisation of the total amount of information in each radiographs[7]. The aim of this study is to determine parents attitude and knowledge towards dental radiography in children.

Material and Method

Data was collected from 42 parents with children in North Chennai population using a structured questionnaire consisting of 8 survey items. The survey was conducted in Saveetha Dental College, Chennai. Patientswho visited the hospital and requiredradiographic examination were selected for the survey. In the questionnaire,details were asked about their knowledge on dental radiograph.

Inclusion Criteria

1. Father
2. Mother
3. Guardian

Exclusion Criteria

1. Dental practitioners
2. Dental assistant

In the questionnaire, details were asked about the experience in exposing X-rays in children, parents level of education, knowledge about the risk and the importance of X-rays. The data thus obtained was subjected to statistical evaluation.

Result

A total of 42 parents with children participated and answered the questionnaire.The majority of respondents accompany their children to their dentist and were aware that exposure from a dental radiograph was too small to put their children at any significant harm, whereas most were not aware that radiation exposure from the environment is higher than radiation from dental radiographs. Of those respondents where parents accompanied their child and radiographs had been taken, 60% felt that the risks of dental radiographs were not explained to them, but 40% said that the dentist explained the reasons for taking dental radiographs(Tab.1).

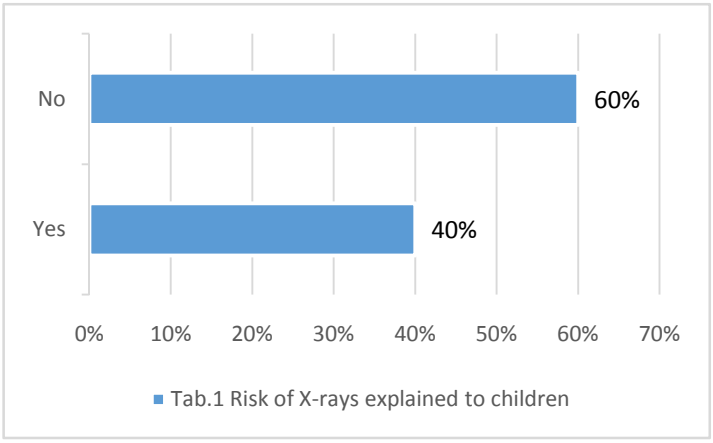

Figure 1: Risk of X-rays explained to children

Parents with children who have had previous dental radiographs were more likely to perceive dental radiographs as ‘useful’ , ‘pleasant’, ‘good’, ‘unpleasant’ (Tab.2). Parents with children who visited the dentist regularly (every six months) were also more likely to perceive that the benefits outweighed the risks.

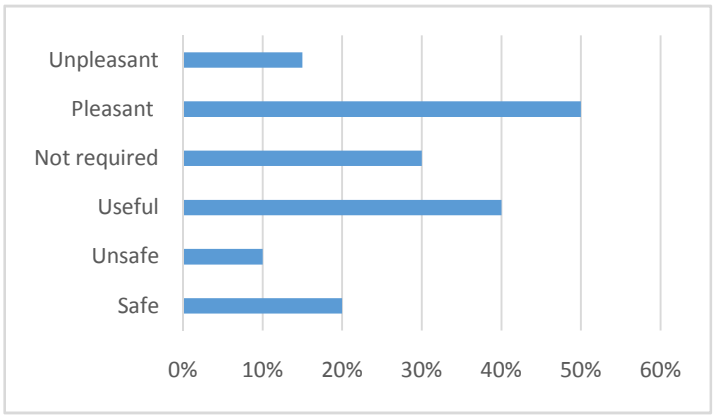

Figure 2: X-rays on Children

A higher level of parental radiographic knowledge was associated with a higher level of formal education(65%) and having children who have had previous dental radiographs reported as ‘useful’(40%) and parents who admitted to lacking knowledge about radiographs perceived them as unpleasant. Parents with average knowledge and who has done undergraduate have reported that X-rays are ‘unpleasant’(Tab.3).Regularity of dental visits

by the parent,type of dental service were found to have no significant associations with attitude or knowledge.

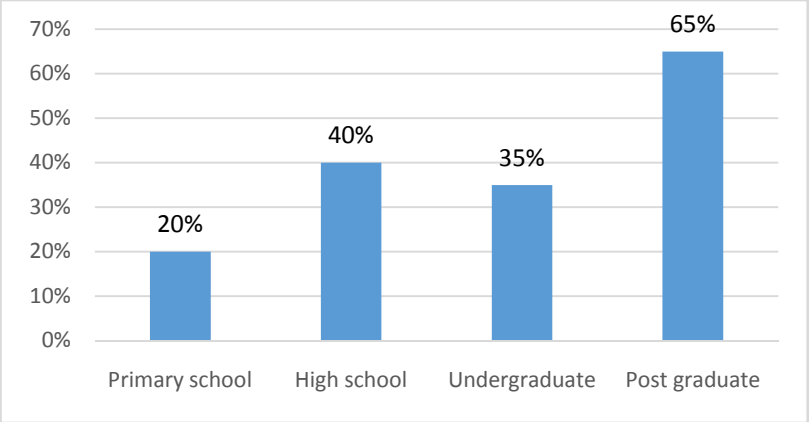

Figure 3: Level of education

Discussion

A key insight gained from this study is that while knowledgeaboutdentalradiographsislow,parentshaveapositive attitudetowardsradiographs.This suggeststhatattitudeisnotprimarilyderivedfromknowledge. On study, a survey done by chiri et al inAustralia reported that Parents with high levels of knowledge about radiographs stated that they thought dental radiographs were safe and beneficial. Conversely, parents who answered the knowledge-based questions incorrectly perceived radiographs as being 'harmful'. Attitudesdevelopovertimeandareorganisedaroundthreemaintypes of beliefs: 1- descriptive beliefs thesearebasedondirect experiences andareofmost value; 2-inferential beliefs these are based on an inferenceprocess, wherebyabeliefisinferredfromother beliefs; 3-informationalbeliefs these arebasedoninformationderivedfromanoutsidesource[8]. Thisstudyfoundthatdescriptive beliefs, basedonparentsexperienceswithradiographstakenfortheirchildren,mayhaveshapedparentalattitudes[9].

Thisstudyindicatedthatparentswhoparticipatedinthesurveyhavehadpositiveexperienceswhenradiographshavebeentaken,andthesepreviousexperienceshaveimpactedontheparentalattitudes.Forexample,parentswithchildrenwhohavehadpreviousdental radiographsandparentswhohavetheperceptionthatradiographsare'good'and'useful'weresignificantlyassociatedwitheachother.

Whilethemajorityofparentshadtheimportanceofdentalradiographsexplainedto them, significantlyfewerparentsreported thattheyhad been informedoftheradiationrisks(40%).Furthermore, over half the respondents were university educated and approximately 60% had experience of dental radiographs. This skewed demographic may have affected the results and therefore the relatively positive attitudes towards dental radiographs found in this population may not extend to the general population[10,11]. The low response rate may have been improved if direct communication was made with the parents and follow-up reminders had been placed in newsletters. It is unknown how many children were giving their parents the newsletter or how many parents read the school newsletter.Reassuringly however, parents who believed the risks were explained to them also agreed that the benefits of the radiographs outweigh the risks. Dentists need to assure patients that they are committed to obtaining excellent clinical results with the lowest possible radiation risk, and that the potential benefits of modern medical imaging procedures almost always far outweigh the associated risks[12,13].

Dental radiographs play an important role in diagnosis and treatment planning. The modalities at the disposal of dentists range from intraoral radiography to cone beam computed tomography. In the field of dentistry, radiation exposure for diagnostic purpose is minimal[14]. However, it is one of the most frequently undertaken radiographic procedures, which is repeated several times during childhood and adolescence. Thus, it is the parent's right to know the associated radiation risks. As per literature available, there are not many studies done to assess the knowledge and attitude of parents regarding dental radiography for their children. Thus, it is unknown whether the fears associated with dental radiography are overstated or the parents are aware about the risks and accept them[15,16].

In a study done by Babu et al.The knowledge of the parents toward dental radiography was found to be relatively low. More than half of the participants were oblivious to the facts such as the damage to the body from dental radiographs is not permanent (58%) or the exposure from dental X-rays is too small to put their child at any significant harm (54%). 56% of the participants were unaware that the exposure to radiation from the environment (e.g. the sun) is higher than the radiation from dental X-rays. However, 58% of the parents knew that radiation from other medical procedures such as chest X-ray is more and, also that if the child wore a lead apron during dental X-ray procedure, it would provide protection against possible

radiation damage[17]. Chiri et al. in their study also reported a low knowledge of the parents regarding dental radiography[6].

Children from low-income and disadvantaged families have a disproportionately higher prevalence of untreated dental caries and lower dental care utilization than higher income group children. A reduction of oral health disparities requires a comprehensive oral health promotion strategy for better oral health among low-income group children. This strategy includes programs such as oral health education, preventive and comprehensive dental care, and social and organizational interventions to address multiple barriers to access and utilise dental care[8]. For these interventions and programs to be successful, the caregivers should be motivated to take action by being aware of their children's oral health conditions and the need for prevention and early interventions. A better understanding of how well caregivers perceive their children's oral health status may improve utilization of dental care services[18].

The radiation dose should be kept as low as can reasonably be achieved both for patient and operator. Usually there will be no damage of clinical significance caused by low level X–rays used in dental radiography. However, the hypothesis in modern radiation protection is that any dose of radiation has the potential to cause biological harm. "It is impossible to relate any specific dental exposure to any specific cancer. All we can say is that the evidence indicates that even very small doses carry the potential for causing cancer" [Smith, 1987]. The probability of long-term effects (stochastic effects) of radiation increases with the dose of exposure, but the severity of the consequential effect when it occurs, such as cancer, is not affected. That means that the probability for cancer is related to radiation dose, but when the disease unfortunately breaks out, the severity of the disease will not depend on the radiation dose. The younger the individual, the higher the vulnerability to radiation is because of the large number of cell divisions occurring in small children. Children also have a higher proportion of the bone marrow located in the skull than adults have. Smith [1992] has shown in a calculation of risk estimates that about one induction of malignant disease per 1,000,000 dental exposures of 5 year old children can be expected. The International Commission on Radiological Protection [ICRP, 1991] has proposed the estimate for a single small dose at the age of 5, which is used in calculations. The risk is reduced when the fastest films available, or digital radiography, are used due to the lower dose needed[19,20]. The image quality could be as good as that of conventional films, but depends on the digital system used. At the

moment there are large variations in quality between the different systems. In a recent study dentists considered the user-friendliness of the handling of the two different digital systems before taking a radiograph as less than for the conventional film [Berkhout et al., 2002]. The patient's comfort was also mentioned as unfriendly especially when the systems were used for children. In the case of digital radiography, the elimination of the chemistry of film processing after taking the radiograph was considered an advantage. Digital images are best viewed on a good computer screen and often loose quality when printed. Such images are like any computer files and may be stored on disks and easily transferred to other computers. In the future, "expert" systems may provide decision support based on automated image analysis [Firestone et al., 1998; White, 1999]. In conclusion, digital radiography has advantages over conventional radiography, but the bulky sensor systems with attached cable and the need for a computer are clinical inconveniences. No studies concerning the use of digital radiography in children are available, but it seems likely that at present time the advantages of these systems are cancelled out by the disadvantages such as acceptance of the sensor or phosphate plate by the child.

Conclusion

Most parents had a positive attitude towards dental radiographs although they had limited knowledge about radiography. This study emphasises the importance of providing accurate and appropriate information so patients and parents have a better knowledge and understanding of dental radiographs. It is imperative for dental health professionals to understand their role in shaping positive attitudes towards dental radiographs.Dentists need to assure patients that they are committed to obtaining excellent clinical results with the lowest possible radiation risk, and that the potential benefits of modern medical imaging procedures almost always far outweigh the associated risks.

Abstract

Aim: To assess the patientsopinion towards dentist appearance, clinical attire, cross infection control, years of experience and their expectations from their dentist.

Materials and method : Patients attending a dental hospital for a consultation appointment were asked to complete a close ended questionnaire comprising 12 questions. A representative sample of patients completed 100 questionnaires over a period of 4 weeks. Their responses were tabulated and analysed statistically.

Result : The study found that majority of patient preferred their own gender dentist and they preferred young dentist with 1-5 years of experience. Some patients preferred dentist wearing white coat while some patients were comfortable with whatever the dentist was wearing. The majority of patients preferred dentist wearing name badge and personal protective equipment. The majority of patients also preferred treatment from colleges and hospitals and preferred dentist who has done MDS/ specialisation. The majority of patients were more comfortable with dentist who is smiling, welcoming and being friendly. Some patients preferred their dentist to talk more while some preferred their dentist to talk appropriately and few patients preferred their dentist to talk less. Dentist having long nails and malaligned or fractured teeth bothered some patient while it didn't bother some patients and some patients didn't notice it.

Conclusion :A considerable amount of research dealing with the professional image of healthcare providers has been produced, but very little of this has been specific to the practice of dentistry. So it is hoped that this study will be informative for dental team and the results should be taken into consideration.

Keywords-*Dentist, Dental Hospitals, Patient, Preferences, Professionalism*

Introduction

Professionalism is an image that promotes a successful relationship with the patient and thus enables the foundation of effective patient care[1]. This fundamental connection is created during the first meeting where the patient forms a initial impression of the clinician[2]. Walsh suggested that proper appearance formed part of the essentialelements for development of this successful professional relationship[3]. First impression can make a difference. How a doctor dresses may be important in determining the success of the patient-doctor relationship[2].Over the years professionalism in health care has had several definitions, many of which are very ambiguous[4].Professionalism is expressed in various ways including the dimensions of competence, ranging from comprehension of basic biology principles to clinical skill; engagement, which includes behaviours and attributes pertaining to empathy and communication; reliability, which pertains to timely access to competence; dignity, which includes treatment of patient, clinical staff, and self; the health care providers dedication to placing the needs of the patient above his or her own needs; and concern for the quality of clinical care[5]. Three broad components of professionalism were introduced by Walsh, suggesting that proper appearance, behaviour, and conversation are essential for a successful relationship[3]. This study also found that patients are more apt to discuss medical issue with a health care provider who is well groomed, has a professional voice, and a confident expression. Physical attractiveness also positively relates to increased patient willingness to disclose symptoms[6, 7].

Dentist attire has been moulded by tradition and fashion over centuries. There have been many changes in the dental field and patient expectations and with increased proportion of female doctors entering the profession that have led to changes in dentist dress code. White coats were worn by dentist for professionalism, identification and hygiene, yet white coats may be a source of, rather than a barrier to cross infection.

Patients will come to dental appointments with some level of expectation regarding their likely outcome. Patients can have a very clear and detailed outcome in mind or it may be more broad and open. Most of the patient's expectation will be realistic; however some won't be.Unrealistic expectations from patient'spresent very real challenges for dentists. If a patient with unrealistic expectations undergoes treatment, it's very unlikely those expectations are going to be met. If a patient's expectations haven't been met, then the patient is going to be unhappy or dissatisfied with the treatment. These unhappy and dissatisfied patients are the ones more likely to complain about the treatment and expect

further corrective treatment or compensation. It's therefore vital that dentists do all they can to help the patient fully understand treatment and the likely and possible treatment outcomes before treatment begins.

A key step in making sure a patient has realistic outcomes regarding treatment is to have an open and honest conversation with them. This will not only provide the patient with further information about their treatment, but will also give the dentist a clearer understanding of the patient's expectations. A dentist's clinical skills are vital to what they do, however effective communication goes a long way in providing positive outcomes.

In order to make the patient'shave realistic expectations, dentists must ensure they explain the treatment and its outcomes to patients using simple and clear terms. Technical and clinical words should be avoided as many patients will not be able to understand these terms. Dentists should also consider how they tailor their language and the information for each individual patient. For a person with language or literacy challenges, they may need information presented in a more detailed manner than other patients. Dentists should also consider using diagrams, pictures or models to assist with understanding where appropriate.

When discussing treatment with a patient, it's important that dentists don't make assumptions about what the patient will or won't understand. It's easy for dentists to become so familiar with what they do and know that they sometimes forget how foreign that knowledge can be to other people. Patients may have varying degrees of knowledge and experience regarding dental treatment. Therefore, what they understand about their treatment will also vary.

When a patient requests a particular form of treatment, this is an occasion when a dentist should be especially careful of the patient's expected outcome. When a patient has requested a form of treatment, the patient has clearly has a idea around what treatment they need to get the outcome they desire. In case if what the patients demanded is not best for them, then the dentist need to be sure they don't rush into providing the patient with the requested treatment and explain them about various treatment options available. As with all patients, there needs to be a thorough assessment and diagnosis process. Then the patient is to be provided with their treatment options, as well as the risks and benefits of those options. There may be treatment options which are more suitable for that patient which the patient isn't aware of. The patient also needs to be made aware of the likely treatment outcomes for each of those treatment options.

The dentist needs to be sure the patient has all required information before consenting to treatment and this includes understanding the likely outcomes. And dentists need to

remember that they’re always responsible for the treatment they’ve provided, regardless of whether it was requested by a patient.

In this study we focused on the importance of patient’s opinion towards their dental professional based on their physical appearance, gender preferences, age preferences, years of experience, dental care system, clinical attire and dentist attitude. In the modern world of clinical dental practice the dentist-patient relationship is moving towards a customer- based service, with increasing demands and pressure. Patient’s opinion keeps changing so it is important for the dental professionals to keep an update on patient preferences which will improve dentist-patient relationship and aids in satisfying the patient. Dentist should groom themselves in a way that they feel is acceptable to their patients.

Materials and methods

A questionnaire based study was conducted of new patients attending an outpatient dental facility for consultation appointments. A self-completion questionnaire consisting of 12 question was developed to gather data on patientopinions on dental clinical attire, name badges and a number of cross-infection control procedures.

Inclusion criteria

Patients attending Saveetha dental college and hospital.

Exclusion criteria

Patients unable to speak English,

Uneducated patients or

For any other reason which would impede their understanding of the questionnaire.

The questionnaires were completed in the waiting area prior to the participants' appointments. A total of 100 questionnaires were distributed over afour weekperiod of which 50 were given to males and 50 were given to females.

The demographic information collected from the questionnaire included the respondent's age, sex, address, occupation and educational qualifications. Of the 100 questionnaires 50 were given to males and 50 were given to females.

Completed patient questionnaires were collected and were analysed for response frequency and the results tabulated. The chi-squared analysis for non-parametric data with the appropriate degrees of freedom was performed on the data to assess responses to the

questionnaire items across patient age groups and gender. Statistical significance was determined at p <0.05.

Results

The surveyed patient pool consisted of 50 males (50%) and 50females (50%). The age of the patients was between 18-50 years age. The mean age of the sample was 29.04 years.

Gender preferences

Of those 50 male patients, 60% of the patients preferred male dentists and 30% of the patients preferred female dentists. 10% of the male patients were comfortable with both the male and female dentists (Figure 1).

Of those 50 female patients, 54% of the patients preferred female dentists and 32% of the patients preferred male dentists. 14% of the female patients were comfortable with both the male and female dentists (Figure 2).

A Chi squared test indicated statistically significance (p<0.05) with the difference between male and femalepatientpreferences.

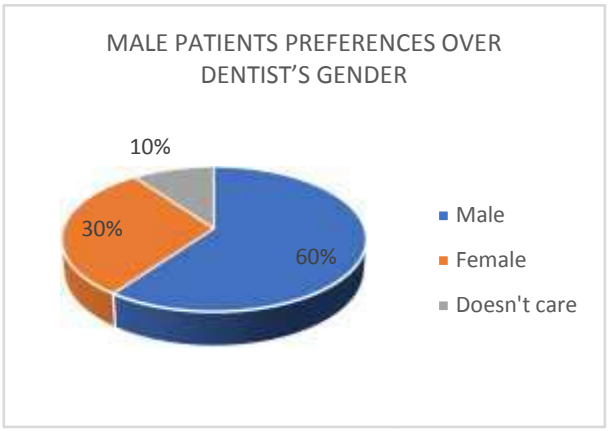

Figure 2: Female Patient's Preference

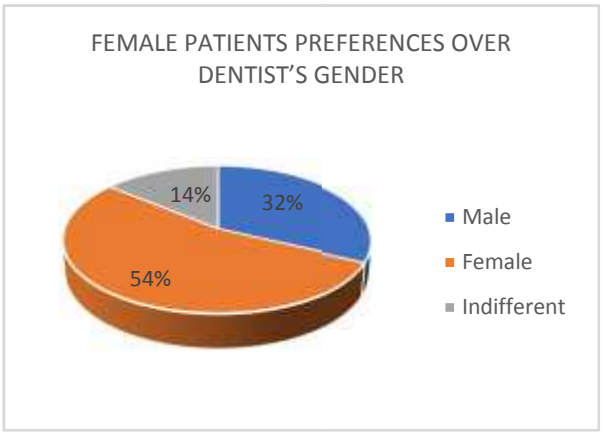
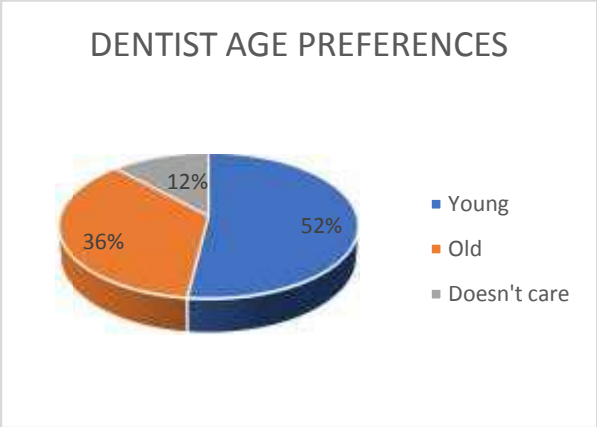


Dentist's age preferences

Of those 100 patients, 52% of the patients preferred young dentists, 36% of the patients preferred old dentists and 12% of the patients were comfortable with both young and old dentists (Figure 3).

Figure 3: Dentist's Age Preference



Dentist's years of experience

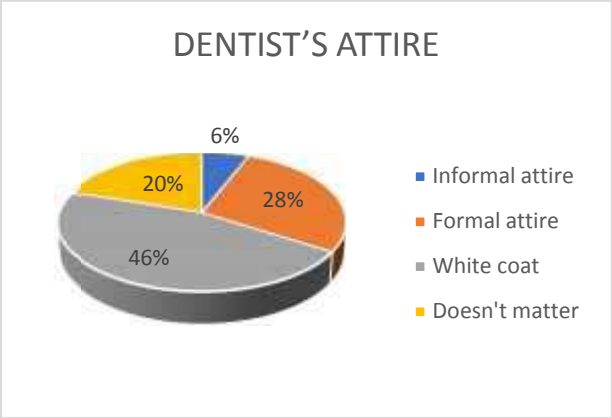
Of those 100 patients, 45% of the patients preferred dentists with 1-5 years of experience, 20% of the patients preferred dentistswith 5-10 years of experience and more than 10 years of experience and 15% of the patients preferred dentists with less than 1 year of experience (Figure 4).

Figure 4: Dentist's Years of Experience

Dentist's attire

Of those 100 patients, 46% of the patients preferred dentists wearing white coat, 28% of the patients preferred dentistswearing formal attire, 20% of the patients didn't care about dentist's attire and 6% of the patients preferred dentists wearing informal attire (Figure 5).

Figure 5: Dentist's Attire



Dentist's with long nails and malaligned/ fractured tooth

Of those 100 patients, dentistshaving malaligned, stained or fractured teethbothered43% of the patients, did not bother 31% of the patients, 26% of the patients didn't notice it (Figure 6). Of those 100 patients, dentists having long nails bothered60% of the patients, did not bother 22% of the patients and 18% of the patients didn't notice it (Figure 7).

Figure 6: Dentist's with Long Nails and Malaligned/Fractured Tooth Malaligned

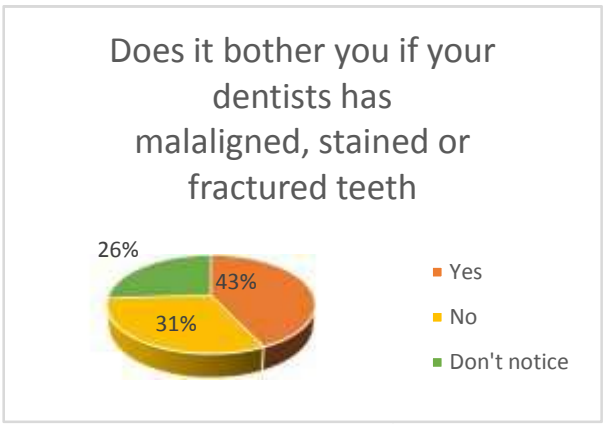


Figure 7: Dentist's with Long Nails

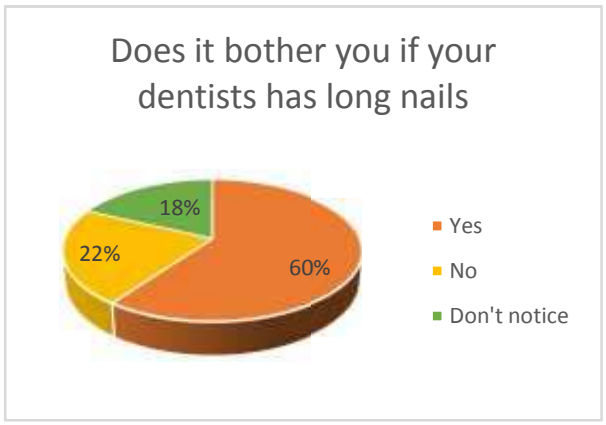
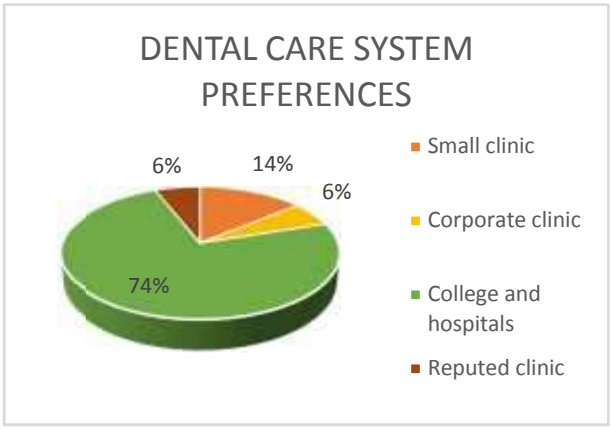


Dental care system preferences

Of those 100 patients, 74% of the patients preferred getting treated in college and hospitals, 14% of the patients preferred going to small clinics and 6% of the patients preferred going to corporate and reputed clinics (Figure 8).

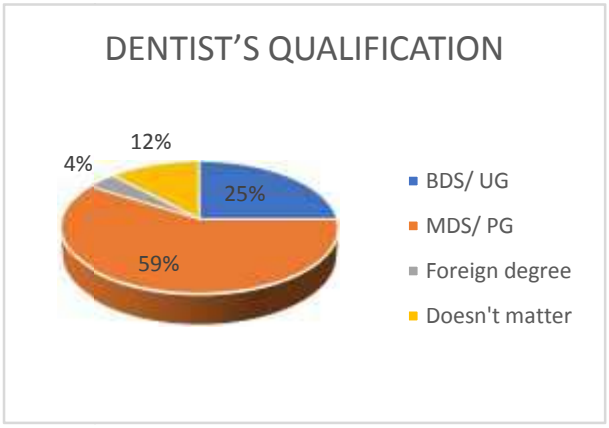
Figure 8: Dental Care System Preferences



Dentist's qualification

Of those 100 patients, 59% of the patients preferred dentists with MDS degree, 25% of the patients preferreddentistswith BDS degree and 4% of the patients preferred dentists with foreign degree. For12% of the patients, dentist's qualification didn't matter (Figure 9).

Figure 9: Dentist's Qualification



Personal protective equipment

Of those 100 patients, 79% of the patients preferred dentists wearing personal protective equipment, 11% of the patients preferred dentistsnot wearing personalprotective equipment and 10% of the patients didn't have any idea about personal protective equipment (Figure 10).

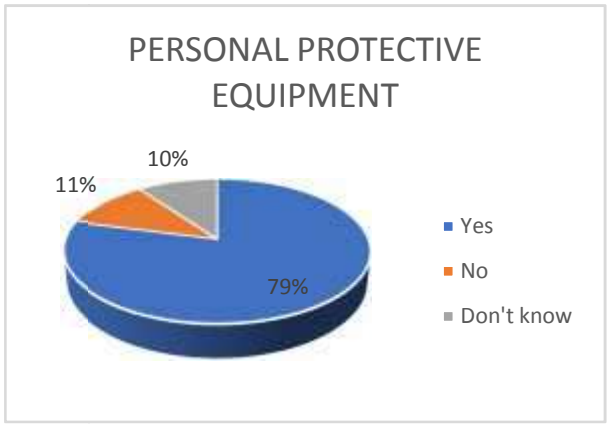


Figure 10: Personal Protective Equipment

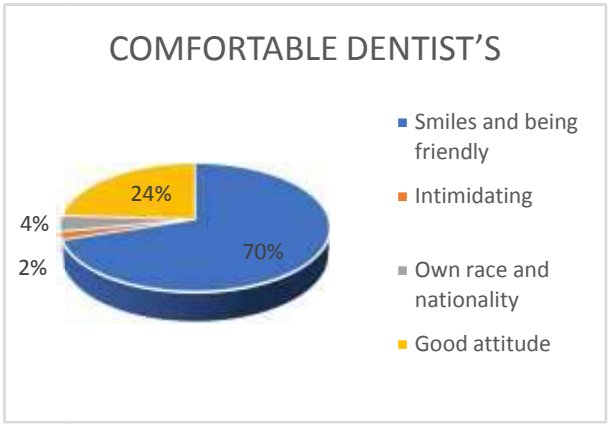
Comfortable dentists

Of those 100 patients, 70% of the patients preferred dentists who is smiling, welcoming and being friendly, 24% of the patients preferred dentists with good attitude, 4% of the patients preferred dentists who belongs to their own race and nationality and 2% of the patients preferred dentists who seemed intimidating (Figure 11).

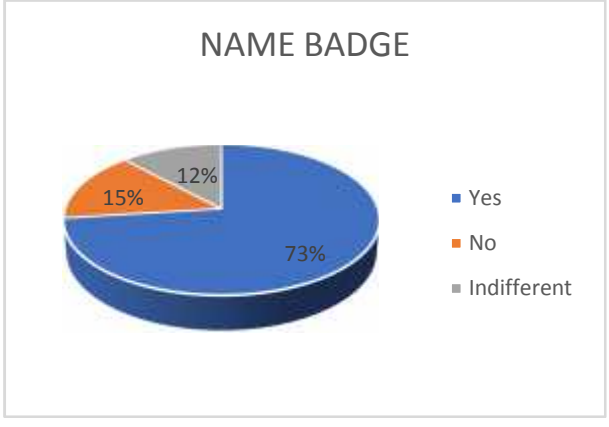
Figure 11: Comfortable Dentist's



Name badge

Of those 100 patients, 73% of the patients preferred dentists wearing name badge, 15% of the patients preferred dentists not wearing name badge and 12% of the patients didn't care about name badge (Figure 12).

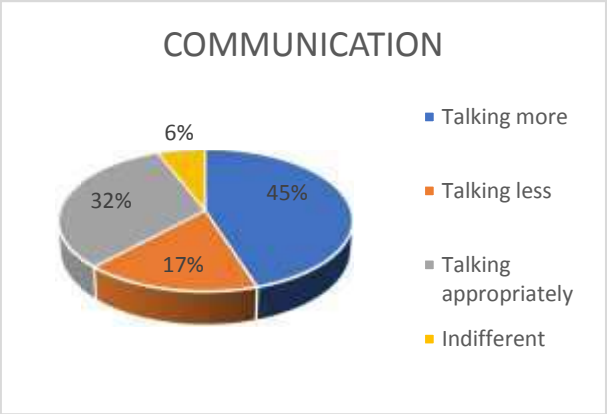
Figure 12: Name Badge



Communication

Of those 100 patients, 45% of the patients preferred dentists talking more, 32% of the patients preferred dentiststalking less, 17% of the patients preferred dentists talking appropriately and 6% of the patients didn't care (Figure 13).

Figure 13: Communication



Discussion

We measured opinions using a questionnaire based study of patients attending Saveetha Dental College and Hospital. Over a four week period of time, sample sizes of 100 patients were achieved. The demographics indicated that 50% consisted of male patients and 50% consisted of female patients with a mean age of 29.04 years.

From the results, it was found that the female patients mostly preferred the female doctors and the male patients preferred the male doctors. From Ackerman-Ross and Sochat studies in 1980, Women seem to prefer female physician and men seem to prefer male physician, so that there is a similar gender preference[8].The patients preferred younger doctors with 1-5 years of experience and with a MDS degree.

The results indicate that patients have strong opinion about dental professional's dress.When the patients were asked about the dentist's attire, majority of the patients wanted the dentists to wear a white coat and they were more comfortable with the formal attire.It is widely reported that patients prefer medical personnel to be smartly dressed, despite debate amongst medical colleagues about the wearing of white coats[9, 10, and 11].

Majority of the patients were concerned about the dentist having long nails and malaligned, stained or fractured tooth.

About 74% of the patients preferred getting treated in the collage and hospitals rather than going to a private clinic.The majority of the respondents (79%) preferred the dentist to wear

headcap, mouthmask, safety glasses and gloves.These results were supported by the findings of Shulman's study in 2001[12].

The patient preferred the doctor who welcomes them with a pleasant greetings and they prefer the dentists to talk more or in an appropriate amount. The study conducted by Deepthi K stated that 55% of the dentists were friendly[13].

The results indicated that majority of the patients preferred dental professionals to wear a name badge.This is in keeping with previous studies found in medical literature[14,15].

In the study conducted by G.N.Karpagam et al. stated that the patient felt secure and safe when the dentist gives proper respect to them[16].

Conclusion

This study has implications for all branches of dentistry where dental professionals strive to deliver a patient-centred service. We have drawn attention to the importance of physical appearance and its effect upon first impressions and interpersonal relationships. From this study we can conclude that patients place a great deal of emphasis on dental professionalsway of dressing and attire. They are supportive of the appropriate use of protective equipment such as face masks and safety glasses and prefer their dentists to wear them. They also prefer dental professionals to wear name badges. Those sampled in this study expressed a strong preference for smartly dressed dental consultants and specialists who wear a white coat. Having this insight into patient preferences should enable individuals and organisations to set standards for appropriate dress codes for dental professionals.

Dentists should be doing all they realistically can to improve the outcomes for their patients and reduce the likelihood of poor outcomes and complaints. Dentists should use their clinical knowledge in conjunction with practical terminology to assist patients to develop realistic expectations.

Future research could focus on patient opinions towards dress codes for other members of the dental team including dental care professionals. It may also be useful to determine patient opinions on dress codes in the general practice and community dental services. In addition, it may be informative to survey patient attitudes towards dental student’s attire. Students operate in an environment where the development of a successful working relationship is paramount given the relative inexperience of the clinician. This is also the setting where our younger colleagues begin to understand the values of professionalism which will positively influence their future practising careers.

Abstract

Introduction: All orthodontic treatment requires patient compliance and hence it is necessary to assess the patient opinion for success of treatment

Aim: The purpose of this study was to assess the rate of acceptance for therapeutic tooth extraction as part of orthodontic treatment. The aim of this study was to analyse the various responses of patients for the extraction of tooth in orthodontic treatment.

Material and Method: This survey was conducted among hundred patients who reported to the dental hospital for orthodontic treatment. A questionnaire containing twenty questions related to orthodontic tooth extraction was formulated.

Result:Among 100 patients, 70% of patients accepted for orthodontic tooth extraction in order to achieve aesthetic results.

Conclusion: This study concluded that patient acceptance and co-operation towards diagnosis and proposed treatment planning is very essential for successful treatment outcome.

Key Words: *Extraction; Patient Acceptance; Orthodontic treatment; Survey; Aesthetics*

Introduction

The most frequent method to gain space for orthodontic purpose is by extraction of one or more teeth. Premolars are most frequently extracted teeth as a part of orthodontic treatment. Extraction of one premolar from each quadrant of jaw provides sufficient space to correct the malocclusion. Extraction of selective teeth can be utilized for correction of malocclusion in both the anterior as well as the posterior segments of the arch. Ideally the arch length and tooth material should be in harmony with each other [1]. Discrepancy in the size of the dentition and arch length can result in crowding of teeth or proclamation of anterior region. In some situations, careful time of extractions may result in spontaneous correction of the malocclusion.

The factors which affect the decision to extract include the patients' medical history, the attitude to treatment, the oral hygiene, caries rates and the quality of the teeth. The decision to extract teeth or not and the number of teeth to be extracted can influence the final result of orthodontic treatment, including esthetics, occlusion, satisfaction of the patients and their families, as well as treatment time. Hence patient's acceptance and cooperation towards diagnosis and proposed treatment planning is essential for successful treatment outcome. This survey was conducted among hundred patients who reported to the dental hospital for orthodontic treatment [2].

All orthodontic treatment requires patient compliance in, for example, maintaining adequate oral hygiene, not breaking or damaging the orthodontic accessories, or simply attending regular appointments. Certain types of malocclusion, however, require additional compliance to ensure treatment success. To correct certain types of Class II malocclusion, especially those of a skeletal origin, patients must wear a headgear [3]. Moreover, in the treatment of Class III malocclusion with maxillary deficiency (patient with growth potential), the use of maxillary protraction face mask is also indicated. In most treatments, the regular use of intermaxillary elastics as an aid in the correction of malocclusion or in the final treatment stage for intercuspation also requires patient compliance. All the resources mentioned above pose patient compliance difficulties involving potential aesthetic concerns [4].

At first, it is extremely difficult to determine whether or not a patient will cooperate, but by observing certain criteria, such as patient behavior in the office, the nature of their relationship with their escort and through an interview with the parents, we can venture some predictions

regarding compliance [5]. These remarks apply mainly to adolescent patients. Overall, adult patients are more compliant than youths because they are more emotionally mature and can, therefore, better understand the importance of this factor in their treatment. When significant cooperation is required it is suggested that a restudy be conducted after a certain period of time since, if compliance is indeed an issue, the orthodontist will not be able to fully rely on this factor to resolve borderline cases [6]. Sometimes lack of compliance can extend treatment time and even lead to reviews of the initial planning, requiring dental extractions.

Class II malocclusions with an adequate lower arch can be corrected by moving the upper teeth distally with the use of elastics or headgear. Both require substantial patient compliance. Alternatively, distal movement can be achieved with mini-implant support, or orthodontic correction can be accomplished by extracting upper premolars, which requires virtually no patient cooperation [7].Some treatment plans can achieve similar results whether conducted with or without extractions (especially borderline cases). However, others may have their treatment outcome jeopardized if planning was based on patient dependent mechanics and the patient failed to respond accordingly.

Extractions and Facial Aesthetics

One of the main indications for orthodontic extractions is to achieve a more harmonious profile in patients with excessive facial convexity secondary to dental biprotrusion. It must be noted, in this regard, that the concept of the ideal profile has changed notably throughout the last century. Several decades ago, the ideal Caucasian profile was flat or even slightly biretrusive, with relatively thin lips; while in recent times more convex profiles have become more popular with a marked lip relief and a wide smile with buccal corridors [10]. This change in tastes for greater facial convexity is mainly for women and in Caucasians; whereas in the male and in oriental races, the flat pro- file is still considered more harmonious. Obviously, this is not the case in Negroid races, one of whose most characteristic features is precisely biprotrusion [11].

The greater tolerance to convexity in our environment has naturally reduced the need for extractions due to biprotrusion and DOD. For example, Proffit performed a study on the changes in the pattern of extractions in the treatment of malocclusions during the last 60 years. It showed that the frequency of extractions was around 30% for the years 1953 and 1993: 40 years apart.

However, interestingly, the analysis in 1968 gave a result of 76%. The explanation given for this high percentage was the trend at the time for removing all teeth outside of the arch. At present, this pro- portion is limited to 5%; 20% down on most studies [12].

However, there are some facial features linked to excessive convexity which are objectionable in any aesthetic framework and put a limit on the extraction option. One of those features is the hyperactivity of the muscles of the chin associated with biprotrusion which, in an effort to close the lips, gives the chin a kind of "golf ball" appearance [13].

The positive effect on the profile of extracting the bicuspids in patients with a normal vertical dimension or a little short and a marked biprotrusion, especially if associated with crowding, is generally clear; thus, there is usually agreement among authors for its indication [14]. This does not occur in the biprotrusive patients with a pattern of mandibular poster rotation and dolicofacial growth. The aesthetic result in these patients of resolving biprotrusion with extractions is unpredictable, if not clearly wrong; so, the clinician is often faced with the choice of obtaining good occlusion at the risk of worsening facial aesthetics, or not altering the profile and accepting the limitations in the resolution of the malocclusion. Obviously, in cases where the dentofacial deformity is more severe, orthognathic surgery allows for both goals, facial and occlusal [15].

Materials and Methods

This survey was conducted among hundred patients who reported to the dental hospital for orthodontic treatment. A questionnaire containing twenty questions related to orthodontic tooth extraction was formulated. Oral examination such as presence of the malocclusion, type of anterior discrepancy such as proclination, crowding, spacing, and presence of impacted tooth, retroclination, and anterior cross bite was included. The treatment plan was explained to the patients and they were requested to complete the questionnaire. Finally, their opinion for extraction of tooth is concluded. If the patient is willing for extraction they were further investigated whether they have any choice to tooth extraction. If the patient hesitates to extract, they were questioned for reasons. Some reasons such as anxiety, pain and discomfort, complications or any health problems. The results of hundred patients are concluded by statistics method.

Result

Among 100 patients 70%of patient accepted for tooth extraction in accordance to treatment plan .30%people refused for extraction due to factors like due to anxiety, discomfort, space, refuse to extract original tooth, fear of loose vision and some health problems.

Table 1: It shows no of patients not willing for treatment due to various reasons ,83.9% avoid extraction due to anxiety,41.9% due to discomfort,19.4% due to fear due to spacing,74.2 due to fear to lose original tooth,45.2% due to health related problems.

Discussion

Tooth arch discrepancy should be evaluated in both the upper and lower arches. But for diagnostic purposes, the lower arch is a priority because of greater difficulty in obtaining space.

When orthodontists are faced with a marked negative tooth-arch discrepancy (TAD) in the lower arch, they will be hard pressed to treat the patient by performing tooth extractions. Small negative discrepancies can, in most cases, be treated without extractions [16]. Thus, space can be obtained by using leeway space (if still possible), stripping, correction of pronounced mesial tipping of lower posterior teeth and small expansions and/or protrusions with the goal of restoring normal tipping to the lower teeth, especially if accompanied by rapid maxillary expansion (RME)[17].

The clinical case 1 illustrates the situation of using leeway space to avoid extractions. The 9-year-old patient had a negative discrepancy in the upper and lower arches. To solve this case, we could choose for upper and lower premolar extractions. Although the profile was slightly convex, we opted for treatment using leeway space in the lower arch, placement of lingual arch during the mixed dentition and rapid maxillary expansion in the upper arch [18]. With this therapeutic approach, we achieved tooth alignment without the need to perform extractions and obtained a straight profile, which probably would have been in worse shape if the case had been conducted with tooth extractions [19].

Another situation typical of negative discrepancy cases is when the need arises to perform tooth extractions but no changes can be made to the facial profile. In the clinical case 2, the patient's facial profile was straight with negative discrepancy in the upper and lower arches and asymmetry in the lower arch with lower midline shift to the right. To solve this case, we chose to extract three premolars (14, 24 and 34). To avoid excessive retraction of anterior teeth towards lingual and deepening of the profile, we used resistant torque in the upper and lower teeth during retraction and avoiding incisor up- righting. The result at the end of treatment was dental harmony in the existent space, with maintenance of the facial profile. Zero or positive model discrepancies require that treatment be performed without extractions, unless the patient has some other associated problem that indicates extraction.

In a clinical study they assessed Some pathologies play a key role in defining orthodontic treatment planning. Patients can have half-formed teeth, ageneses, ectopias, abnormal shapes or even carious processes, and endodontic lesions that indicate tooth extraction. During diagnosis these conditions should be considered as they may change in certain situations the choice of the tooth or teeth to be extracted.

In patients with an indication for premolar extraction due to a sharp negative model discrepancy, but with extensive decay in the first permanent molars, these teeth are a viable extraction alternative for the premolars. In asymmetric malocclusions, where only one tooth must be extracted, if the patient happens to have an anomalous tooth, this tooth should be selected for extraction. Many other pathological conditions such as cysts, abnormal roots and periodontal problems indicate the extraction of teeth. Thus, the different pathologies greatly contribute to orthodontic treatments involving extraction.

Clinical case 8 is of a female 10 year-old patient and illustrates the importance of pathologies in deciding which tooth to extract. She was in the mixed dentition phase and had an Angle Class I malocclusion, 3 mm anterior open bite, mouth breathing, upper midline shifted due to a missing tooth and skeletal Class II relationship. The maxilla was slightly contracted with no crossbite and she had a 6 mm lower arch model discrepancy.

An analysis of the lateral radiograph. Showed skeletal Class II (ANB = 6o), vertical facial growth pattern (SNGoGn = 42o and Y axis-SN = 74o), upper incisors retroclined (1. NA = 16o)

and linguoversion (1-NA = 3 mm) and lower incisors protruding and in labioversion (1. NB = 29o and 1-NB = 5 mm), although the latter were well established in the mandible (IMPA = 89°). The profile was straight (S-UL=+1/S-LL=+1).

In malocclusions with skeletal discrepancies it is crucial for the diagnosis and prognosis of the case to check whether the patient is still undergoing significant facial growth. Maximum pubertal growth spurt occurs approximately at around 11-12 years in girls and 13-14 years in boys, subject to individual variations. The most widely used method for assessing skeletal age is through a hand and wrist radiograph, by analyzing the size of the epiphyses relative to the diaphyses. If a patient is in his/her development period it is not possible to correct a skeletal dysplasia with the use of appliances that produce orthopedic effects.

If a malocclusion can be corrected with growth response (growth redirection), clinicians can handle the case without extractions.

In a case with these characteristics. We achieved skeletal and dental correction using headgear associated with a fixed orthodontic appliance. Initially, this 11 year-old patient had a convex profile, Skeletal Class II (ANB = 8o), Angle Class II, division 1, 2 mm lower TAD, 8 mm overjet, 5% overbite, well positioned upper incisors (1.SN = 101o), protruding lower teeth (IMPA = 99) and in- creased lower facial third. As an aggravating factor, the patient had a thumb-sucking habit, mouth breathing and a predominantly vertical resultant growth (SN.GoGn = 40o).

In this case, we opted for the use of combined pull headgear with a greater vertical component to correct the Class II by differential anterior displacement of the mandible (due to growth) associated with the use of Class III elastics to reposition the lower incisors.

Proffit and Fields developed a guide of contemporary procedures for evaluating extraction in Class I cases with crowding and/ or protrusion. The authors reported that in negative lower arch discrepancies below 4 mm tooth extraction is rarely required, except in cases of incisor protrusion or posterior vertical [20].

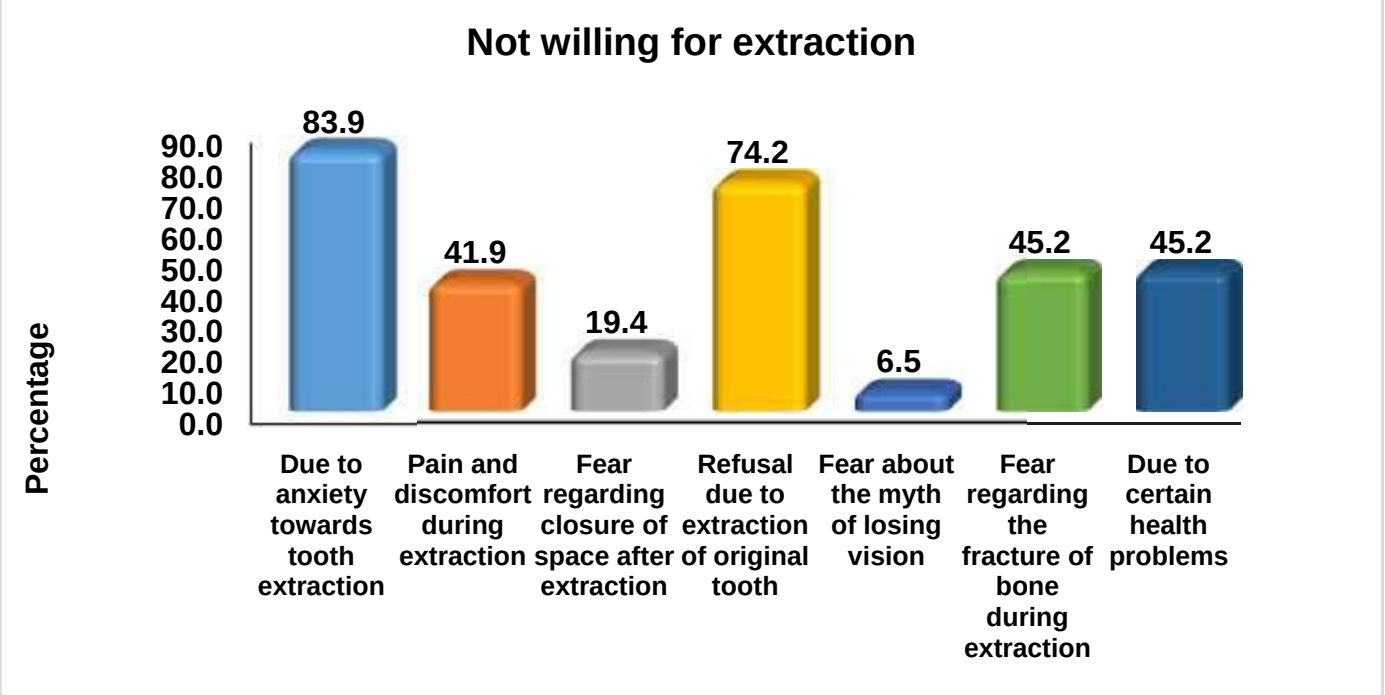
Graph 1: It shows no of patients willing for extraction of tooth according to treatment plan,it shows 33.3% of patients are willing for extraction

Graph 2: It shows no of patients not willing for treatment due to various reasons ,83.9% avoid extraction due to anxiety,41.9% due to discomfort,19.4% due to fear due to spacing,74.2 due to fear to lose original tooth,45.2% due to health related problems.



Questionarrie format:

Patients acceptance for orthodontic tooth extraction

1)Name:

2)Age:

3)Sex:

4)Occupation:

5)Income:

6) Chief complaint:

7) Malocclusion:Yes / No

Angle's Class I / Class II- Division I/DivisionII. /Class III

Type of anterior discrepancy:

Proclination/Crowding/Spacing/Presence of impacted tooth/Retroclination/Anterior cross bite

8) Why were you interested in orthodontic treatment?

9) Was the treatment plan explained to you prior to starting the treatment : Yes/No.

10)Have you undergone extraction before: Yes/No

11) Do you have any knowledge on the extraction process : Yes/No

12) Are you willing for extraction if required: Yes/No

If yes:

13)In accordance to the treatment plan: Yes/No

Choice to tooth extraction: Yes/No

If yes:

Lower incisor:

First premolar:

Second premolar:

Lingually blocked upper lateral canine:

Severely blocked out canine:

Figure 1: Questionnaire for assessing patient acceptance for orthodontic extraction

CONCLUSION:

Due to the process of the evolution there is a great incidence of arch length tooth size discrepancy. This survey was conducted among hundred patients who reported to the dental hospital for orthodontic treatment. A questionnaire containing twenty questions related to orthodontic tooth extraction was formulated in different types of malocclusion. This necessitates the need for tooth extraction to gain space. However, patient reporting orthodontic practice are not aware of same. Hence this questionnaire is formulated to know the patient response to tooth extraction as part of orthodontic treatment. This study concluded that patient acceptance and co-operation towards diagnosis and proposed treatment planning is very essential for successful treatment outcome.

Abstract

Introduction: The basic aspect of modern endodontics is painlessness and effectiveness of the treatment of diseased dental pulp. The disease of dental pulp is mainly caused due to dental caries. Dental caries is a common chronic disease prevalent all over the world. It is a microbiologic disease which manifests as demineralization of hard tissues of the tooth. If detected earlyits management can be done easily via conservative techniques like restorations. As it progresses to involve the vascular tissue of the tooth it may cause symptoms such as pain and swelling. This leads patients to seek dental care. Additionally, dental decay may cause tooth loss which can reduce the ability to eat fibrous foods, leading to dietary deficiencies. Root Canal Treatment is a procedure that uses biologically acceptable chemical and mechanical treatment in the root canal system to eliminate pulpal and peri-radicular diseases and to promote healing and repair of peri-radicular tissue.The aim of this research is to study the patients knowledge and attitude in Endodontic treatment.

Material and Method: A total of 13 questions was prepared and distributed to 100 patients in Saveetha Dental College which included to record patients knowledge and attitude towards root canal therapy.

Result: 68% participants responded positively, but when asked in detail what root canal treatment does and whether it is a complicated the responses were mixed and majority didn't know or were not sure.

Conclusion: From the self-prepared questionnaire and based on the responses acquired, it can be seen that on an average 58% of responses for all fifteen questions turned out to be positive and patients who had prior knowledge about root canal treatment were interested in proceeding post endodontic treatments to increase the success of RCT

Key Words:*Endodontics, knowledge, treatment, root canal, crown*

Introduction

Endodontics is the branch of dentistry that deals with diseases of the tooth root, dental pulp, and surrounding tissue in human. It is a profession based on the work with other people, so several factors should be considered during clinical decision-making process. The process of clinical decision-making is the essence of everyday clinical practice. This process involves an interaction of application of clinical and biomedical knowledge, problem-solving, weighing of probabilities and various outcomes, and balancing risk-benefit. Although most clinical deci- sions are based on 'traditional' clinical criteria, they are also influenced by a wide range of non-clinical factors. Non-clinical influences on clinical decision-making affects medical decisions and it includes patient-related factors such as socioeconomic status, quality of life and patient's expectations and wishes, physician-related factors such as personal characteristics and interaction with their professional community, and features of clinical practice such as private versus public practice as well as local management policies.

Endodontic treatment is performed to save the natural tooth. Most of the dentists agree that there is no substitute for healthy and natural teeth in spite of many advanced restorations. Publications on patient's awareness of endodontic procedures are rarely presented. Patients perceived problems related to endodontically treated teeth are an important consideration for all dental practitioners. Contemporary endodontics is developing continuously. It concerns not only the instruments, but also the treatment procedures. The basic principle of modern endodontics painlessness and effectiveness of the treatment (1,2). The conviction of difficulties related to root canal treatment, including pain associated with it has been functioning among patients. It raises many concerns, which often lead to cancelling the visits to the dental office(3,4).Many patients admit that they feel the stress related with the planned endodontic treatment. In all professions based on the work

with other people, understanding of motivational processes and skills of using knowledge is very important.(5,6).

In dentistry, RCT is the most feared procedures of all treatments. Dentist asserts that modem root canal treatment is relatively painless because pain can be controlled. Major setback of root canal treatment is that most patients lack the knowledge. They do not know what root canal treatment entails and what the benefits of such treatment are. Most patients fear root canal treatment because it is painful.(7)

Indications of root canal treatment are irreversible pulpitis, periapical periodontitis, crown fractures involving the pulp, acute per apical abscess, when want to create post space, construction of an over denture and when the vitality of pulp is doubtful. Root canal treatment is contraindicated in patient with poor oral hygiene, poorly motivated patients, patients with poor general health, and the very old and in patients with infective endocarditits.

Material and Method

A self-administered questionnaire was prepared and distributed to 100 patients in Saveetha Dental College (convenience sampling) during their regular dental visits in order to assess the knowledge and attitude towards endodontic treatment. A total of 13 questions were included to record patients knowledge and attitude towards root canal therapy. These ranged from personal details such as name, age etc to specific questions relating to awareness about root canal therapy, perceived barriers to undergo the same and sources of knowledge regarding Endodontics.The findings of this study will be used to come up with strategies to improve knowledge and practice of patients towards endodontic treatment.

1.Are you aware of Root Canal Treatment (RCT)?
A) Yes
B) No
C) Not sure
2.Do you know that RCT is a treatment involving cleaning and restoring up to the root of the
tooth
A) Yes
B) No
C) Not sure
3.Do you think RCT is a complicated procedure?
A) Yes
B) No
C) Not sure
4.Have you undergone RCT procedure?
A) Yes
B) No
C) Not sure
5.Was it painful during treatment?
A) Yes
B) No
C) Not sure
6.Do you know how long will take it to finish the RCT procedure?
A) Yes
B) No
C) Not sure
7.Would you prefer root canal treatment to tooth extraction?
A) Yes
B) No
C) Not sure
8.Do you know the price of RCT procedure?
A) Yes
B) No
C) Not sure
9.Do you know that procedures like permanent filling or crowns after root canal treatment determine the success of RCT done?
A) Yes
B) No
C) Not sure
10.Do you intend to continue treatment procedures after RCT
A) Yes
B) No
C) Not sure
11.What do you do in case of toothache?
A) Go to a dentist
B) Use home remedies or pain killers
C) Not sure
12.How do you know about endodontic treatment?
A) Through Media or internet
B) Parents or friends
C) Dentist
D) Don't know
13.Why do you think root canal treatment is necessary?
A) Toothache or Broken tooth
B) Change in tooth colour
D) Not sure

Figure 1: Questionnaire

Results

The study records based on the questionnaire showed that 90 out of 100 patients contacted regarding the study responded positively and agreed to participate. Among the 90 patients, 22 patients were of 18-24 age group, 34 patients were of 25-30 age group, 19 of them were 31-40 age group, 15 of them 41-60 age group of the total participants.

Table 1: Awareness of Root canal treatment.

Responses	Number Out Of 90 Participants
Yes	61
No	15

Out of 90 participants, 61(68% of 90 participants) respondents were aware that of root canal treatment, other 15(17% of 90 participants) of them were not aware and 14(15%)of them were not sure.

Table 2: Response for RCT treatment involving cleaning and restoring up to the root of the tooth.

Responses	Number Out Of 90 Participants
Yes	31
No	42

31 (34%) participants responded positively , 42(47%) didn't know and the remaining 17(19%) were not sure.(Tab.2)

Table 3: Patients response towards RCT procedure.

Responses	Number Out Of 90 Participants
Yes	30
No	19

30 (33%) out of 90 participants think RCT is complicated procedure and 19(21%) of them responded that RCT is not a complicated procedure and 41(46%) of them did not know about it.(Tab.3)

Table 4: Patients who have undergone RCT procedure.

Responses	Number Out Of 90 Participants
Yes	43
No	10

43 out of 90(48%) participants responded that they have undergone RCT procedure, 10(11%) of them did not undergo RCT procedure and 37(41%) of them were not sure if they had undergone RCT procedure. (Tab.4)

Table 5: Patients response during treatment.

Responses	Number Out Of 90 Participants
Yes	25
No	18

25 out of 43(28%) participants who underwent RCT procedure felt that RCT was painful, 18(20%) of them felt it was not painful.

Table 6: Patients knowledge about the duration of the procedure

Responses	Number Out Of 90 Participants
Yes	31

No	42

Out of 90 participants, 31(34%) of them responded that they know how long will it take to finish RCT procedure, 42(47%) of them agreed that they do not know about the time taken to finish the RCT procedure and 17(19%) of them were not sure about it.

Table 7: Patients preference on root canal treatment.

Responses	Number Out Of 90 Participants
Yes	30
No	21

More than 44% of the respondent preferred root canal treatment and 23% consider extraction as the ultimate method. The remaining 40% had doubts about their preference. (Tab.7)

Table 8: Patients response about the cost of RCT procedure.

Responses	Number Out Of 90 Participants
Yes	28
No	22

Twenty-eight (31%)of respondents out of 90 participants admitted to knowing the price of root canal treatment(Tab.8).

Table 9:Patients success rate on permanent filling or crowns after root canal treatment.

Responses	Number Out Of 90 Participants
Yes	23
No	19

Table 9 shows that 23 (26%) of 90 participants knew that procedures like permanent filling or crowns after root canal treatment are mandatory to determine the successof RCT .

Table 10: Patients response on continuing procedures after RCT.

Responses	Number Out Of 90 Participants
Yes	26
No	19

Out of 90 participants, 26(29%) respondents said that they intend to continue treatment procedures after RCT (Tab.10)

Table 11: Patients response in case of toothache

Responses	Number Out Of 90 Participants
Go To A Dentist	60
Use Home Remedies Or Pain Killers	20

Tab.11 shows the behaviour of patients in case of a sudden, severe toothache. The majority of patients 67% would go immediately to a dentist after the first symptoms and 22% of respondents admit to using the “home remedies” to combat ailments.

Table 12: Patients knowledge on endodontic treatment.

Responses	Number Out Of 90 Participants
Through Media Or Internet	49
Parents Or Friends	18
Dentist	9
Don’t Know	14

Tab.12 shows about the knowledge of the patient about endodontic treatment. Out of 90, 49(54%) of the participants responded that they knew endodontic treatment through media or internet , 18(20%) knew from friends and family, remaining 9(10%)through dentist and 14(26%) participants did not know.

Table13: Patients opinion on Root canal treatment.

Responses	Number Out Of 90 Participants
Toothache Or Broken Tooth	60
Change In Tooth Colour	23

Tab.13 shows attitude of the respondents. Out of 90 participants, 60(66%)of them responded that RCT is necessary in case of toothache or broken tooth, 23(26%)of them responded that RCT is necessary in case of change in tooth color.

Discussion

The study was conducted based on a self-prepared questionnaire circulated among 100 patients visiting Saveetha dental college, Chennai. Out of 100, 90 patients answered the questionnaire and 10 patients were not interested to answer the questionnaire. There are 15 direct questions focused on the awareness and attitude towards endodontic procedures in the participants. Majority of participants belonged to the age group 25-30 years (38%). When asked pertaining to their awareness maximum (68%) participants responded positively, but when asked in detail what root canal treatment does and whether it is a complicated the responses were mixed and majority didn't know or were not sure(Tab.1). The participants were then questioned about their previous experiences with root canal treatment, a maximum of 48% participants had prior experience, and about 28% responded they didn't have pain during the procedure and 20% had pain during treatment. When asked about the duration to complete root canal treatment and would they prefer it over extraction of tooth, only 33% - 34% responded positively and majority had doubts. To the next questions about the cost, success and further treatment, about 25% - 31% responded positively that they knew about the cost and were aware and willing to follow up treatments like permanent restoration and

crowns to improve the success rate, but still a majority didn't know the cost and further treatment options. A large percentage of participants 67% responded that they would go to a dentist when there is incidence of pain and remaining 33% chose either home remedies or were not sure. About 84% of participants had prior interest in knowing about endodontics either through media, friends, family and dentists; majority of participants believed root canal treatment is necessary in case of broken tooth or pain associated with the tooth.

The main aim of a Root canal treatment is the complete removal of the connective tissue and the destruction of residual microorganisms found in infected root canals and an effective seal in order to prevent recolonization of the root canal system with bacteria. Thus the primary endodontic treatment goal must be to ensure root canal disinfection and to prevent re-infection. Irrigating solutions play a very large role in disinfecting the root canals. To remove smear layer and disinfect canals are the main objective of cleaning and shaping. Today, use of laser to remove smear layer and to disinfect root canals has increasingly attracted the attentions. (8)The complexity of the root canal system, presence of numerous dentinal tubules in the roots, invasion of the tubules by microorganisms, formation of smear layer during instrumentation and presence of dentin as a tissue are the major obstacles in achieving the primary objectives of complete cleaning and shaping of root canal systems.(9)

In recent years, endodontics has been one of the fastest growing areas of dentistry. The use of modern tools, rubber dam, and the microscope in daily practice, significantly influence the quality and durability of treatment effects. All endodontic procedures should be performed with a rubber dam, which should be considered standard care. The purpose of rubber dam protection in dentistry on whole cannot be overemphasized (10). Patients more often do not identify the endodontic treatment as the most unpleasant procedure. Endodontic procedures with associated pain is felt as moderate, rarely sharp. In addition, patients can benefit from many forms of local anesthesia, and the use of nitrous oxide, which according to recent reports, enhances the effect of their actions. Another form of premedication are preoperative intravenous sedatives and analgesics. In extreme cases, general anesthesia is the alternative. A study conducted by Klages et al. demonstrates that patients visiting the dental office expect pain usually larger than that actually experiencing during treatment [11].One of the fastest growing areas of dentistry in the recent years is observed to be endodontics. The quality and

durability of the treatment has become more effective after the use of Modern tools (the rotary nickel-titanium files which has enabled a quicker root canal preparation, as these instruments produce a uniformly tapered canal configuration with minimum canal transportation and also reduces the incidences of periradicular irritation and post-operative discomfort but only about one fifth of respondents use these rotary instruments in root canal preparation whereas the others use Non-rotary manual endodontic files), rubber dam, and microscope in daily practise. (12)

The conviction of difficulties related to root canal treatment, including pain associated with it has been functioning among patients. It raises many concerns, which often lead to cancelling the visit to the dental office. Many Patients admit that they feel the stress related with the planned endodontic treatment. Publications on patients' awareness of this type of procedures are rarely presented. Contemporary endodontics is developing continuously. It concerns not only the instruments, but also the treatment procedures. The basic principle of modern endodontics is painlessness and effective of the treatment. There are many methods providing the patient with comfort by reducing pain during treatment: local and conduction anesthesia, nitrous oxide or even general anesthesia. Successful RCT depends not only on specific factors like root canal infection, complexity of root canal morphology, etc. Majority of RCT in India is provided by general dental practitioner. Various investigations are therefore, carried out to explore the standard of RCT carried out by them.The antibiotics should be used judiciously for well defined indications in endodontics. The antibiotics use should only be considered as an adjunct to non surgical endodontic therapy. At the end the dentists should have a sound knowledge about the endodontic indications for the prescription of antibiotics to restrict and prevent the misuse and overuse of antibiotics.(13)

According to the study done bySisodia N et al, it indicates that most of the barriers reported to acceptability of root canal therapy could be overcome by patient education and creating increased general awareness about oral health and different dental procedures through school dental health education programs.(14) As the dentist is the most common source of information for most patients, the onus of appropriate dissemination of knowledge lies with them. This can be done most effectively in the Dental office by placing pictoral pamphlets which describe RCT, crowns in the waiting area. Non-operating office staff can additionally

help in increasing awareness by explaining the importance of retaining and replacing teeth while the patient is in the waiting area.(15,16)

In all professions based on the work with other people, understanding of motivational processes and skills of using knowledge is very important. These factors are particularly important in everyday practice of a dentist(17). Properly conducted interview with the patient helps in deciding on the appropriate therapeutic treatment, especially with regard to endodontics, which often prevents tooth loss(18).Since the beginning of modern-day endodontics, there have been numerous concepts, strategies, and techniques for performing pain-free and reasonable cost root canal treatment. The level of patients' knowledge and awareness regarding root canal treatment may influence their decision-making and choice; it may be obstacle to get the treatment(19,20).

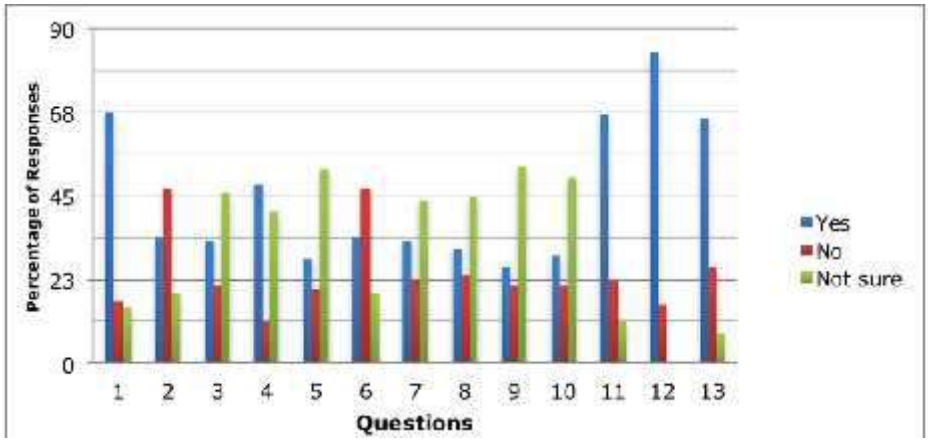

Figure 2: Representing patient's knowledge on Root Canal Treatment.

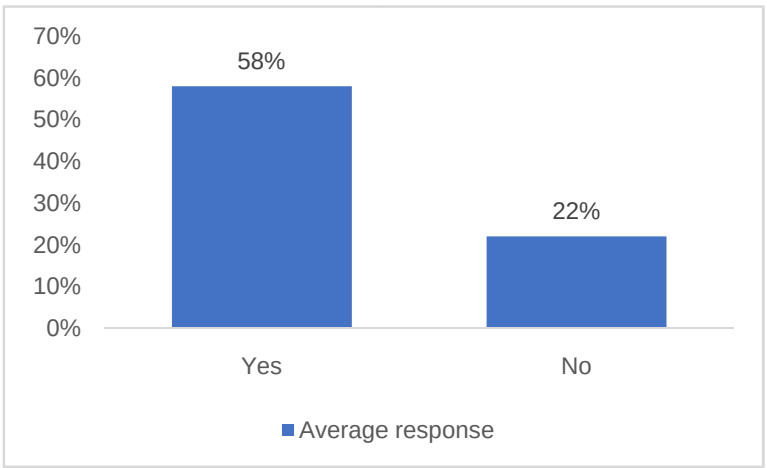

Figure3: Graph representing majority of 58% had prior experience, and 22% of the patients were not aware of the procedure, 30% were not sure.

Conclusion

From the self-prepared questionnaire and based on the responses acquired, it can be seen that on an average 58% of responses for all fifteen questions turned out to be positive and patients who had prior knowledge about root canal treatment were interested in proceeding post endodontic treatments to increase the success of RCT. The next major focus was the 30% of participants who responded doubtfully, steps can be taken to clear their doubts by means of explaining what and how Root Canal Treatment and other endodontic procedures done, it can be done during the diagnosis and treatment planning or even during dental camps and awareness programs conducted separately.

Perception of Exodontia

N.S.Harini[1], Loganathan[2], Sankari M[3]

Graduate Student[1], Reader[2], Department of Oral Surgery[2],

Professor[3], Department of Periodontics,

Saveetha Dental College, Saveetha University,

Saveetha Institute of Medical and Technical Sciences.

Abstract

Aim: The aim of the study is to study and analyse the perception of exodontias (tooth extraction).

Objective: The objective of this study is to assess the most difficult tooth to extract, and the frequent complications faced by the dentists during dental extraction, the instruments used for extraction of upper and lower third molar, and the preference of antibiotics and analgesic by the dentists.

Materials And Methods: A Survey had been conducted among 50 dentists to assess the perception of exodontia. Questionnaire survey which includes 9 questions. The analysis was statistically analysed and represented with bar graph diagram.

Results: Among 50 dentists, 13 dentists(p value=0.069) that the most difficult tooth to extract according to them was upper left second molar and another 13 dentists (p value=0.069) opted that upper left third molar was the most difficult tooth to extract. Root fracture is the most common complication according the dentists conducted in the survey(p value=0.015). Cryers are mostly been selected during extraction of upper third molar(p value=0.126) and coupland elevators are mostly used for exodontia of lower third molar(p value=0.713). The normal blood glucose level range to select patients for extraction lies mostly on 70-110mg/dL where 41 dentists among 50 of them opted for this range(p value=0.152). The normal blood pressure for extraction tends to be 120/80-160/94mmHg where 23 dentists preferred in the survey(p value=0.620). The most preferred antibiotic in

therapeutic extraction is broad spectrum antibiotics where 33 dentists among 50 opted for this(p value=0.011). The most common alternative way preferred by the dentists when local anaesthesia does not work is through intra ligamental way where 25 dentists opted in this study(p value=0.035). Penicillin and metronidazole is the most preferred antibiotic in dento alveolar abscess where 34 among 50 dentists opted for this(p value=0.035).

Conclusion: Our study answers the difficulties and common questionable issues that arise in dental extraction. Awareness must be created about the medical issues like normal blood pressure range among dentists to be increased.

Introduction

Tooth extraction is one of the dental treatments which should be considered the last option. A decrease in the number of teeth may result in poor dietary habit and deterioration of quality of life[1]. The number of extracted teeth can serve as an indicator of socio-economic and oral hygiene level[2]. Extraction of permanent teeth is performed for several reasons including dental caries, periodontal disease, orthodontic reasons, impacted teeth, failed dental treatment, prosthetic indications and other reasons.

An understanding of the reasons why teeth are extracted is essential to improve oral health outcomes. A large number of cross-sectional studies have investigated for tooth loss in different countries. Dental caries was the main cause for tooth loss[3-9], but a few studies revealed that a greater proportion of tooth extractions were due to periodontal disease[10-12].Extraction of teeth is the commonest surgical procedure carried out in the dental surgery setting by the practicing dental surgeon[13]. From a historical perspective, dental extractions have been used to treat a variety of diseased conditions, and as a method of severe punishment or torture to obtain forced confessions from suspected criminals[13-15]. Also, before the advent of antibiotics, chronic tooth infections were sometimes linked to a variety of health-related problems and removal of such diseased tooth was therefore a common treatment option for various medical conditions[14]. Likewise, it was once a common practice

to remove the front teeth of institutionalized psychiatric patients who had a history of biting[15]. Tooth mortality, which is mainly a reflection of untreated dental caries and periodontal disease, is considered as a crude but useful measure for the dental status of a community[16]. Causes of tooth extractions had large geographical and cultural differences between various regions in a country and from one country to another[16,17]. Extraction of teeth is the most common procedure carried out in oral surgery clinics. The final consequence of most dento-alveolar diseases is tooth loss, mostly through routine tooth extraction[18].Reasons for routine tooth extractions have been widely reported in medical literature[18-22]. In addition, postoperative pain and discomfort, loss day at work as well as healing complications have been well reported in the immediate postoperative period following non-surgical (routine) tooth extraction[23-25].

Materials And Methods

Study Designand Sample

To address the research purpose, a survey study is been implemented by conducting a questionnaire survey which contains 9 questions. All the questions were most relevant for the perception of exodontia. The sample size for this study is 50. The questionnaire survey was then distributed among 50 dentists in Saveetha Dental College in the department of oral and maxillofacial surgery. The participants answered the survey without any bias and after the survey was over, data was collected and statistically analysed and the results were tabulated.

PERCEPTION OF EXODONTIA – RESEARCH QUESTIONNARE

AGE:

SEX: MALE / FEMALE

YEAR OF PRACTICE:

1. **WHICH IS THE MOST DIFFICULT TOOTH TO EXTRACT?**

18 17 16 15 14 13 12 11 21 22 23 24 25 26 27 28

48 47 46 45 44 43 42 41 31 32 33 34 35 36 37 38

2. WHAT IS THE MOST COMMON COMPLICATION ENCOUNTED IN EXODONTIA?

A. BLEEDING
B. ORO-ANTRAL COMMUNICATION
C. DENTOALVEOLAR FRACTURE
D. TUBEROSITY FRACTURE
E. ROOT FRACTURE
F. OTHERS

3. WHICH INSTRUMENT DO YOU USE FOR EXTRACTION OF UPPER THIRD MOLAR?

A. STRAIGHT ELEVATORS
B. FORCEPS
C. CRYERS
D. COUPLAND ELEVATORS
E. OTHERS

4. WHICH INSTRUMENT DO YOU USE FOR EXTRACTION OF LOWER THIRD MOLAR?

A. STRAIGHT ELEVATORS
B. FORCEPS
C. COUPLAND ELEVATORS
D. OTHERS

5. WHAT IS THE NORMAL BLOOD GLUCOSE LEVEL DO YOU PREFER FOR EXTRACTION?

A. 40 - 60 mg/dL (fasting)
B. 70 – 110 mg/dL (fasting)
C. 120 – 140 mg/dL (fasting)

6. WHAT IS THE NORMAL BLOOD PRESSURE DO YOU PREFER FOR EXTRACTION?

A. 100/70- 140/90mm/Hg
B. 90/60- 140/94 mm/Hg
C. 120/80-160/94 mm/Hg

7. WHICH ANTIBIOTIC DO YOU PREFER IN THERAPEUTIC EXTRACTION?

A. NARROW SPECTRUM
B. BROAD SPECTRUM
C. METRONIDAZOL
D. NO ANTIBIOTICS
E. OTHERS

8. HOW WILL YOU MANAGE IF THE LOCAL ANASTHESIA IS NOT ACHIEVED?

A. MAIN TRUNK ANASTHESIA
B. INTRA PULPAL INJECTION
C. INTRA LIGAMENTAL INJECTION
D. ANTIBIOTIC AND RECALL

9) WHAT IS YOUR PREFERENCE OF ANTIBIOTICS IN DENTO ALVEOLAR ABSCESS CASES?

A. PENICILLIN AND METRONIDAZOLE

B. ORNIDAZOLE AND OFLOXIN

C. CLINDAMYCIN

D. CIPROFLOXACIN

E. OTHERS

DATA ANALYSIS

To analyze the data, counts and tabulation were calculated. Results were obtained for survey responses, and was estimated according to the study. Bar charts were used to present the results.

Results

FIGURE 1:RESULTS SHOWING THE MOST DIFFICULT TOOTH TO EXTRACT:

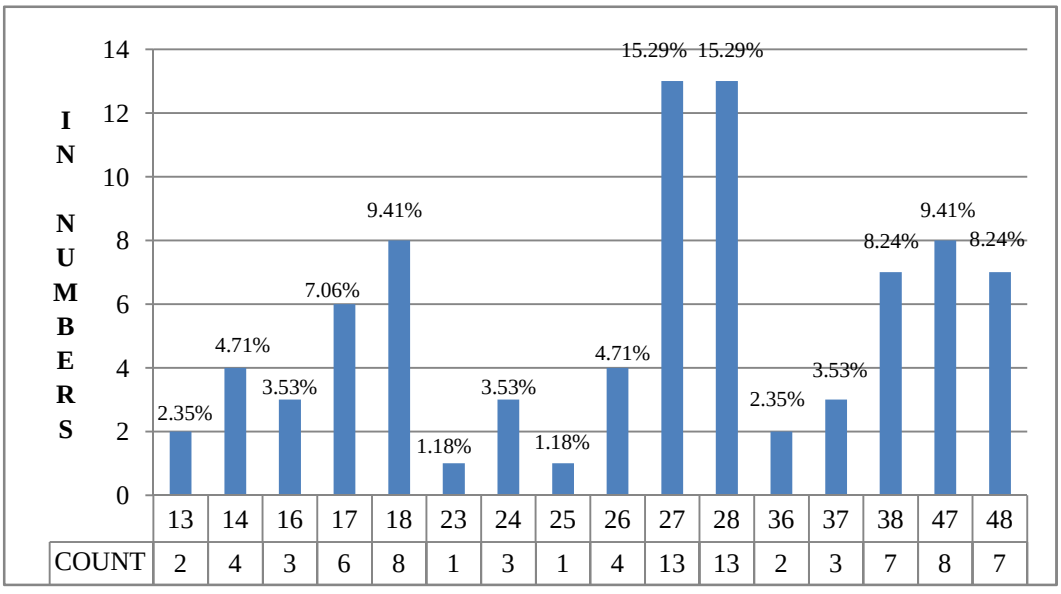

FIGURE 2: BAR GRAPH SHOWING MOST COMMON COMPLICATION ENCOUNTED:

Discussion:

Tooth extraction remains a major cause commonly performed procedure in developing countries[26,27] Tooth loss has significant socioeconomic, quality of life general health, and psychological consequences[27,28] Indeed, tooth loss has become a global public health concern of immense proportion[28,29]. Despite being preventable, dental caries and periodontal disease remain the most common reasons for tooth extraction, especially developing nations.[30,31]

The reasons for tooth extraction and the number of teeth extracted in a population have been linked to the oral hygiene, level of education, socioeconomic status, and individual quality of life[28,30,32].Degree of urbanization has also been found to affect the pattern of tooth extractions[33,34]. Moreover, oral disease burden and its etiological factors exhibit inter- and intra-regional variations[35]. Dental extraction has a psychological influence on the patients both before and after the surgery. It is always a delicate task in the hands of dentists to prepare the patients before any dental extraction procedure and it is also critical to provide appropriate expectations of the discomfort the patients would experience[36]. Local anesthetic solutions are utmost importance in the field of dentistry. The main use of the local anesthetic drug is that they eliminate pain[37]. Extraction is the most common procedure done in

dentistry in india, and a knowledge about post extraction complications and their management can prevent the occurrence of untoward sequelae following extraction[38]. Third molar impactions are common. The impaction rate for third molars is higher than for any other teeth[39].Root fracture is the most common complication according the dentists conducted in the survey. Thus, extracting a tooth without fracturing the root is technique sensitive and thus need to be practiced well by the dentists to avoid further complication. Cryers and coupland elevators are the most preferred instruments for extraction of upper and lower third molar respectively,which makes us understand that these instruments makes extraction more easier. 70-110mg/dL is the normal range of blood glucose during exodontia and 120/80-160-94mmHg is the normal blood pressure for exodontia, thus making it significant before initiating extraction.The most commonly preferred antibiotic in therapeutic extraction is broad spectrum antibiotics, the other alternative when LA does not work is intra ligamental and penicillin an metronidazole are the most preferred in dento alveolar abscess. Awareness must be created about the normal blood pressure range among dentists to be performed in cases of exodontia.

Conclusion:

Thus, exodontia is very well understood from the survey that 27 and 28 are the most difficult teeth during exodontia, root fracture is the most common complication, cryers and coupland elevators are the most preferred instruments for extraction of upper and lower third molar respectively, 70-110mg/dL is the normal range of blood glucose during exodontia and 120/80-160-94mmHg is the normal blood pressure for exodontia, the most commonly preferred antibiotic in therapeutic extraction is broad spectrum antibiotics, the other alternative when LA does not work is intra ligamental and penicillin an metronidazole are the most preferred in dento alveolar abscess. Awareness must be created about the normal blood pressure range among dentists to be performed in cases of exodontia.

Perception of Pain during Orthodontic Treatment among School Students Undergoing and not Under Going Orthodontic Treatment

BhavaniGanesan[1], Jaiganesh Ramamurthy[2]

Graduate Student[1], Reader[2], Department of Periodontics

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: This study helps to understandthe perception of pain which is felt by the school students, who are undergoing orthodontic treatment and also the perception of pain related to orthodontic treatment who are not undergoing orthodontic treatment. This will help the dentist to understand the perception of pain much better.The aim and objective of the study was to evaluate the perception of pain in orthodontic treatment among school children who are undergoing and not undergoing orthodontic treatment.

Materials and Methods: The school student consists of two groups: group 1 consist of students who are undergoing orthodontic treatment and group 2 consist of students who are not undergoing orthodontic treatment. Questionnaire forms weregiven to both the group of students. In Group 1 questions were based on the difficulties they underwent during treatment. In Group 2 questions were based on their perception about orthodontic treatment. The data was analysed statistically to achieve the results.

Results: From the results it has been found that 64% of the people had experienced a pain during orthodontic treatment most probably at day1, 22% of the people had experienced a pain at day3 and 14% of the people had experienced pain beyond 5th day. Student who were not undergoing orthodontic treatment; 68% of the people felt orthodontic treatment was painful and 32% of the people felt that orthodontic treatment was not painful.

Conclusion: This study helps the orthodontist to understand the perception of pain towards the orthodontic treatment and conduct the treatment accordingly to make the treatment as painless as possible.

Key Words: *Pain, treatment, perception, students, Orthodontics*

Introduction

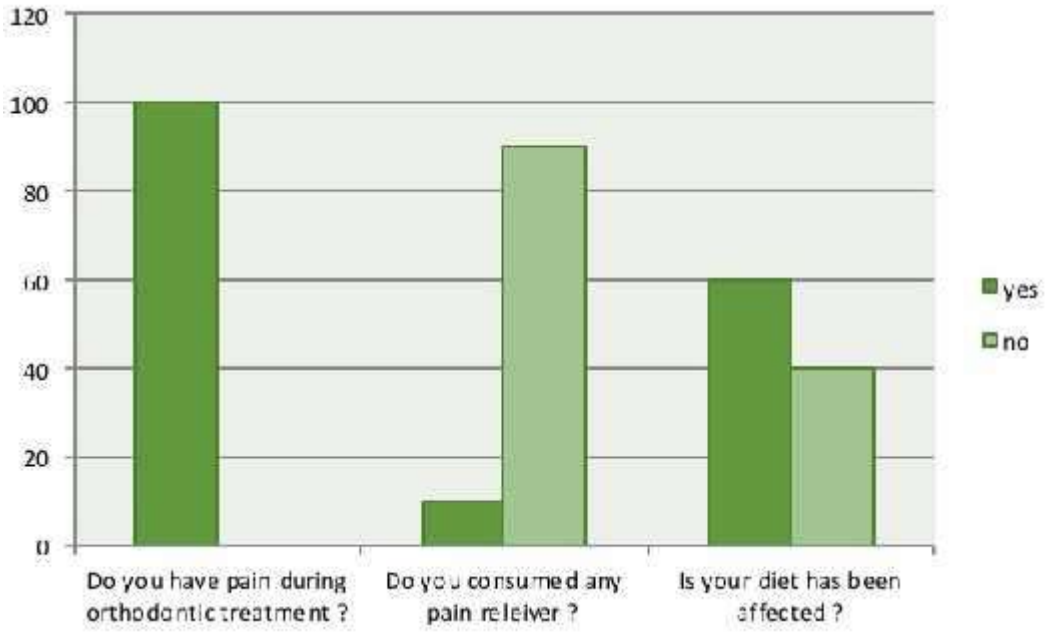
Pain and discomfort to the patient are more common during orthodontic treatment Malaligned teeth often result into food lodgment esthetic and psychological problems in patients.The main cause of pain during orthodontic treatment is the application of forces to induce tooth movement, separator placement, and during debonding[1,2] Pain is influenced by gender, personality factors, individual pain threshold, magnitude of force applied, and motivation.[3-5]TMJ, lips, gingiva and tongue are not affected by fixed appliances.[6-8] Discomfort is mainly localized at the teeth. Among the soft tissues, Ulcer sites are localized at the inner side of the cheeks[9,10] Ithas been found that well-informed patients has lesser pain perception and require fewer medications.The aim of this study was to evaluate perception of pain towards orthodontic treatment by questionnaire survey.

Materials and Methods

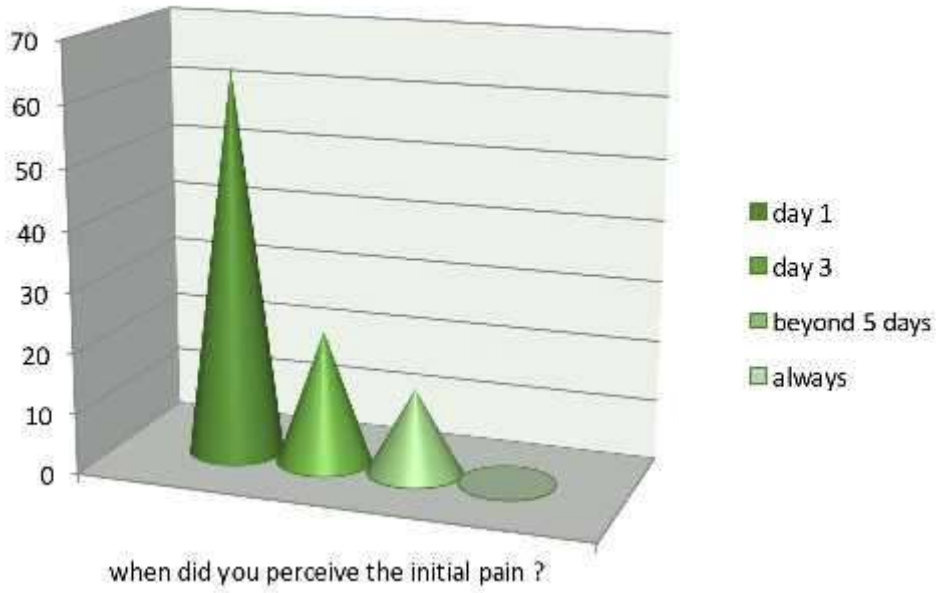
The questionnaire study was conducted on 100 patients with Group I consist of 50 people who were undergoing orthodontic treatment and Group II consist of 50 people who weren't undergoing orthodontic treatment. The questionnaireform was relevant to pain perception toward orthodontic treatment. For evaluation of perception pain, there were twoquestionnaires independently given for each group. The questionnaire forms will be differs from both the groups, questions related to their experience towards orthodontic treatment was given to the group of people undergoing orthodontic treatment, whereas questions about their perception towards malocclusion and orthodontic treatment was given to people who are not undergoing orthodontic treatment.The data was analyzed statistically to achieve the results.

Results

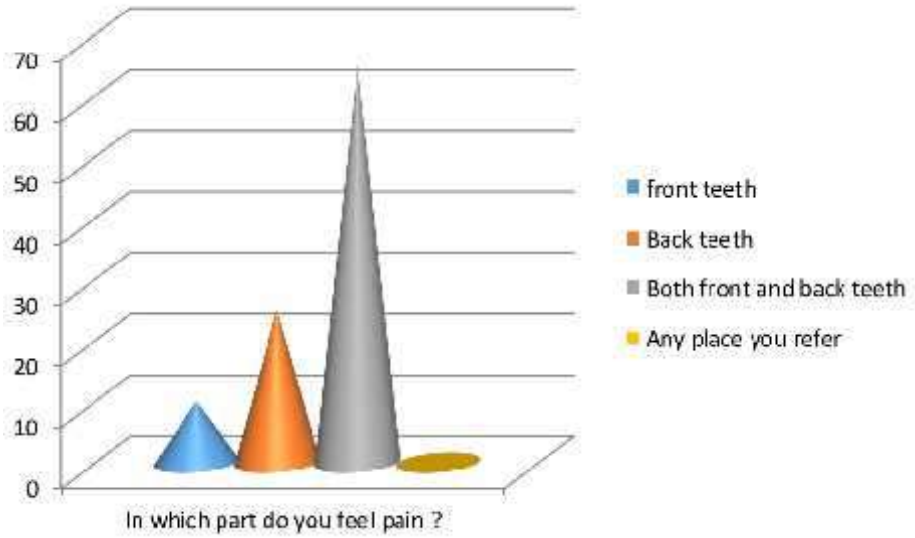
Group 1



Graph 1: Presents 100% of the people reported that there was pain during the orthodontic treatment.10% of the people have consumed pain reliever during orthodontic treatment and 90% of the people have not consumed pain reliever during treatment.60% of the people has a disturbance in their diet and 40% of the people has no disturbance in their diet.

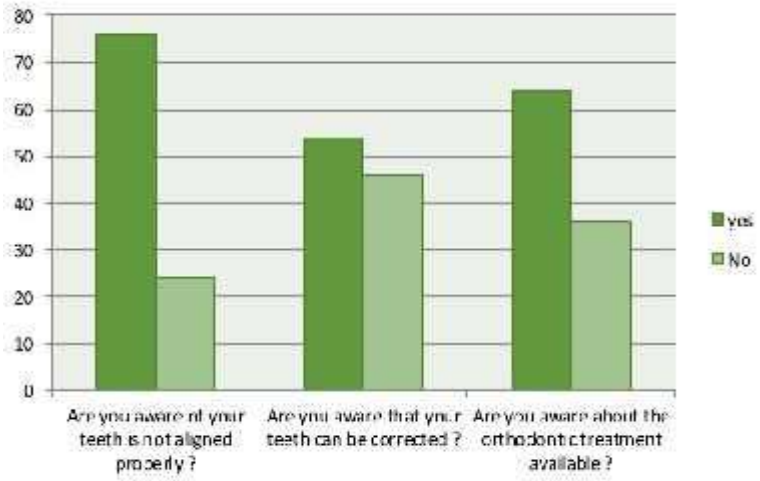


Graph 2: Represents 64% of the people feel that they perceived the initial pain at day1, 22% of the people feel that they perceived the initial pain at day 3, 14% of the people feel that they perceived the initial pain at beyond day 5and no one feel that they had pain always.

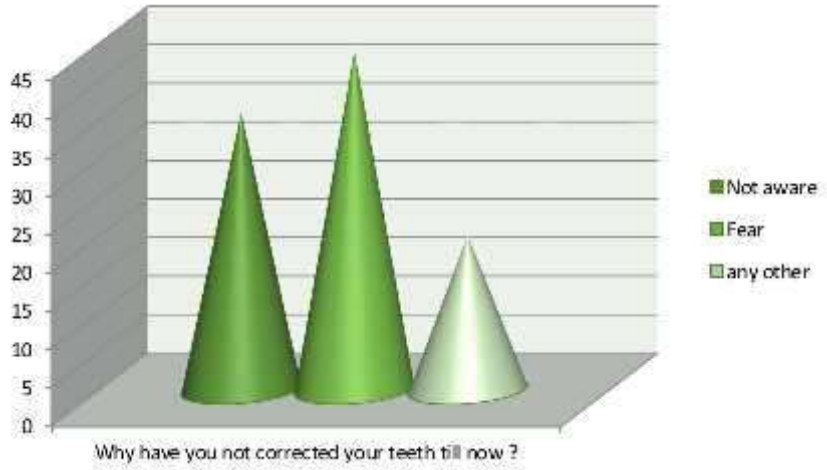


Graph 3: Represents 10% of the people feel that they had a pain in front teethregion ,25% of the people feel that they had a pain in back teeth region,65 % of the people that they had experienced a pain in both front and back teeth region.

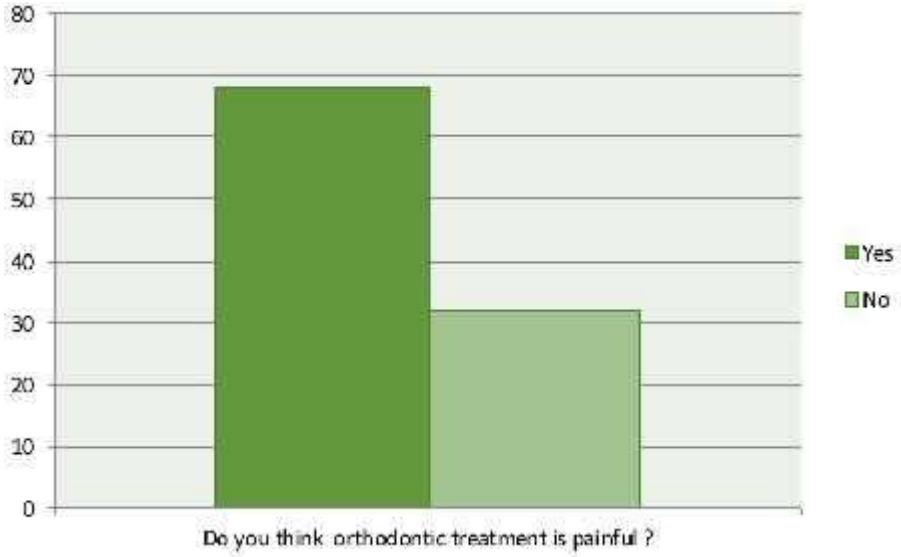
Group II



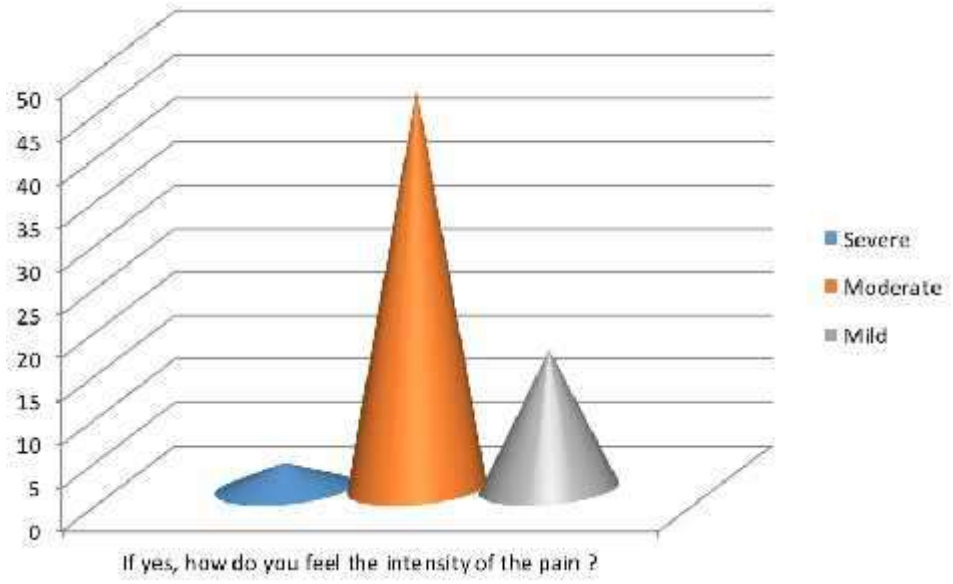
Graph 4: Represents 76% of the people reported that they were aware of their teeth were not aligned properly and 24% of the people reported that they were not aware about their teeth is not aligned properly.54% of the people reported that they were aware of their teeth can be corrected and 46% reported that they were not aware of their teeth can be corrected.64% of the people reported that they were aware about the orthodontic treatment available and 36% of the people reported that they were not aware about the orthodontic treatment available.



Graph 5: Represents 36% of the people reported that they were not aware of correcting their teeth, 22% of the people reported that they had fear of correcting their teeth, 10% of the peoplehad some other reason of not correcting their teeth.



Graph 6: Represents 68% of the people feel orthodontic treatment is painful and 32% of the people feel that orthodontic treatment is not painful.



Graph 7: Represents 6% of the people reported the intensity of the pain issevere, 46% of the people reported the intensity of the pain ismoderate, 16% of the people reported the intensity of the pain is mild.

Discussion

The study was performed on 100 people from which 50 people who have undergoing orthodontic treatment and another 50 people who have not undergoing orthodontic treatment.From the results it has been found that 64% of the people had experiencedapainduring orthodontic treatment most probably at day1, 22% of the people had experienced a pain at day3 and 14% of the people had experienced a pain at beyond 5 day.

The people felt the pain has reduced as progress the weeks, no one experienced a pain always till orthodontic treatment completed.Periodontal pain is caused by a10% of the people feel that they had a pain in front teeth region,25% of the people feel that they had a pain in back teeth region, 65 % of the people that they had a pain in both front and back teeth region.Now the reason of this could be that individual's perception of pain varies from person to person.The pain seems to more initially because of the inflammatory reaction andmovement of the tooth and also the pressure were felt maximum on the first day.

The forces applied could start coming down after the day 1 because of fatigueof elastic materials which are used and as the tooth moves the pressure on the tooth also reduce.Theresults have been found from the people who are not undergoing orthodontic treatment.68% of the people felt orthodontic treatment is painful and 32% of the people felt that orthodontic treatment is not painful.68% of the people reported that orthodontic treatment is painful from that 6% of the people reported the intensity of the pain is severe, 46% of the people reported the intensity of the pain ismoderate, 16% of the people reported the intensity of the pain is mild.

Every treatment in the dental specialty has its own set of complications orthodontic therapy being no exception. Dental aesthetics are a key factor in overall physical attractiveness, which also contributes to self-esteem. This is one of the main reasons for patients to undergo Orthodontic treatment.[11-15] Although Orthodontic treatment has many recognized benefits, including improvement in dental health, function, appearance, and self-esteem, nevertheless Orthodontic appliances can cause unwanted complications if adequate care is not taken during the treatment. It is important that the patients are aware of these potential risks, so that they can know their responsibilities and the expectations placed on them during the treatment. This ensures in achieving successful results without any adverse effects during and after completion of orthodontic treatment.[16-20].

Conclusion

This study helps the orthodontist to understand the perception of pain towards the orthodontic treatment and conduct the treatment accordingly to make the treatment as painless as possible.

The study was performed on 100 people from which 50 people who have undergoing orthodontic treatment and another 50 people who have not undergoing orthodontic treatment.From the results it has been found that 64% of the people had experiencedapainduring orthodontic treatment most probably at day1, 22% of the people had experienced a pain at day3 and 14% of the people had experienced a pain at beyond 5 day.

The people felt the pain has reduced as progress the weeks, no one experienced a pain always till orthodontic treatment completed.Periodontal pain is caused by a10% of the people feel that they had a pain in front teeth region,25% of the people feel that they had a pain in back teeth region, 65 % of the people that they had a pain in both front and back teeth region.Now the reason of this could be that individual's perception of pain varies from person to person.The pain seems to more initially because of the inflammatory reaction andmovement of the tooth and also the pressure were felt maximum on the first day.

The forces applied could start coming down after the day 1 because of fatigueof elastic materials which are used and as the tooth moves the pressure on the tooth also reduce.Theresults have been found from the people who are not undergoing orthodontic treatment.68% of the people felt orthodontic treatment is painful and 32% of the people felt that orthodontic treatment is not painful.68% of the people reported that orthodontic treatment is painful from that 6% of the people reported the intensity of the pain is severe, 46% of the people reported the intensity of the pain ismoderate, 16% of the people reported the intensity of the pain is mild.

Every treatment in the dental specialty has its own set of complications orthodontic therapy being no exception. Dental aesthetics are a key factor in overall physical attractiveness, which also contributes to self-esteem. This is one of the main reasons for patients to undergo Orthodontic treatment.[11-15] Although Orthodontic treatment has many recognized benefits, including improvement in dental health, function, appearance, and self-esteem, nevertheless Orthodontic appliances can cause unwanted complications if adequate care is not taken during the treatment. It is important that the patients are aware of these potential risks, so that they can know their responsibilities and the expectations placed on them during the treatment. This ensures in achieving successful results without any adverse effects during and after completion of orthodontic treatment.[16-20].

Conclusion

This study helps the orthodontist to understand the perception of pain towards the orthodontic treatment and conduct the treatment accordingly to make the treatment as painless as possible.

Abstract

Introduction: Tooth loss in patients may cause oral discomfort, mastication problems, displacement of adjacent and opposing teeth in order to cover edentulous spaces and also the alignment of the teeth. Loss of teeth not only adversely affects the body physiology but also disturbs the psychology of the individual**.** The aim of this study is to identify the perception of patients about the impacts and needs of prosthesis at the time and after extraction of the tooth.

Materials and Methods: Teeth play an important role in mastication. Tooth loss can be treated with various types of prosthetics, depending on the severity which aids in maintaining the mastication properly. Most of the patients are not seeking treatment immediately after tooth loss evenwhen it is needed because of unawareness about the treatment. The purpose of this study is to evaluate the patients' perception about the impacts and prosthesis need at the time and after extraction of the tooth. A convenient sample of 101 patients were clinically evaluated and answered for the questionnaire about prosthetic needs. Data were collected at the time of extraction and at the time interval of onemonth. Statistical analysis has been done with the collected data.

Result: This study is designed comparatively to evaluate and analyze the patients' perception about the impacts and needs of prosthesis at the time and after tooth loss. The reason of this study is to aware people about their knowledge on benefits, risk and impact on prosthesis and about impacts on untreated tooth loss.

Conclusion: Self- perception about tooth loss and prosthodontic needs at the time and after an interval of 3 month from extraction didn't have much significant change among patients. Better function and oral discomfort were mentioned as major benefit and risk of prosthesis. Treatment demand was low due to lack of knowledge and awareness, poor interest and motivation.

Key Words: *Perception, prosthesis, treatment, mastication, extraction.*

Introduction

Tooth loss in patients may cause oral discomfort, mastication problems, displacement of adjacent and opposing teeth in order to cover edentulous spaces and also the alignment of the teeth. Loss of teeth not only adversely affects the body physiology but also disturbs the psychology of the individual [1]. Even though the knowledge about the impacts of tooth loss and the importance of tooth loss on general health [2, 3] among the patients is less, the psychological disturbances are directly related to the acceptance of the artificial prostheses by the patient [2]. Prosthodontics is concerned with the replacement of partial or complete loss of teeth and oral function due to tooth or tissue damage [4, 5]. The patient's self- perceived prosthodontic desire is based on number of absent teeth, age, gender, position of the missing tooth, oral discomfort, functional disability and socio-economical status especially when anterior tooth are not involved [6, 7]. If anterior tooth involved, the prosthodontic treatment is indicated to restore the patient aesthetics and self-esteem [5]. In a recent study, most patients gave financial constraints & rumours for not replacing teeth. Cost was the main barrier for obtaining dentures [8, 9]. Another issue is the time taken by the patients between tooth losses and seek for prosthodontic treatment. Some of the patient’s perception might change after a period of time from extraction and may seek prosthodontic treatment or implants. The physical effects and emotional status of the clinical conditions are widely commonly explained for both partially dentate and edentulous individuals [10-13]. Prosthodontic rehabilitation of partially or completely edentulous patients is important, since the definitive treatment can improve oral function, aesthetics and quality of life of most patients [14]. This study is done to assess the patient's self-perceived prosthodontic need at the time of extraction and short interval after tooth loss.

Materials and Methods

A convenient sample of 101 patients were reported to our dental institution Saveetha dental college about tooth loss are examined and interviewed. Data's are collected at two stages: at the time of extraction and 3 month after extraction. Patient's exclusion criteria were third molar surgery (complete dentition), extraction for orthodontic purposes, emergency dental problems with acute symptoms, and patients unable to answer the questionnaire or who refuse to participate. All patients scheduled for elective dental extraction were included. Clinical examination was performed at the time of tooth extraction before surgery. It includes socio-demographic variables and clinical variables such as position, extension and number of previous edentulous areas, and reasons for extraction, location of edentulous spaces and number of teeth indicated for extraction. After 3 months, patients were contacted by phone and/or mail. Patients were questioned if they had replaced the extracted teeth and, if not, the reason why they did not demand for immediate replacement.

Results

A total convenient sample of 101 patients who visited our dental institution with age group range from 16 to 70 years were included in the study (45.5% male; 54.5% female). 43.6% patients are at low educational level and 57.4% patients have completed their basic education.

At the Time of Extraction

Table 1 shows that, at the time of extraction, most patients (91.1%)had prior edentulous spaces. Most of the edentulous spaces were present in both anterior and posteriorly of about 42.6%. There ismultiplenumbers of edentulous spaces of about 50.5% present in both the arches (34.7%). Only 52.4% of patients undergone prosthodonticrehabilitation for previously extracted tooth.86.2% of patients optedfixed partial dentures in both anterior and posterior teeth(37.9%) or only posterior teeth (36.2%), and 34.5% of dentures were inthe both arches or upper arch respectively.

In Table 2 shows that patients' perceptions of impacts associated totooth loss were considered high at the time of extraction (33.7 to61.4%). Although 51.5% of patients felt immediate replacement ofextracted teeth is more important, only 51.5% intended to treat edentulous spaces shortly after extraction. 61.4% patients felt thatprosthodontics replacement is necessary to solve the problems followedby tooth extraction, 51.5% considered that

immediate placement isnecessary and 51.5% of patients intended to seek treatment immediatelyafter extraction. 50.5% of patients believed that prosthesis does not have potential risk. 60.4% of patients concern about their dentalcondition and 52.5% of patients are satisfied with their dentalcondition. The patients felt that loss of teeth does not affect theirgeneral health, appearance and digestion of food of about 66.3%, 55.4% and 55.4% respectively. Only 58.4% of patients felt difficulty to chewthe food after tooth loss.

Table 3 shows frequency of patient's perceptions of benefits and riskof prosthodontic treatment and reason for not treating. 63.6% and53.5% of patients felt better function and aesthetics has a benefitrespectively. 60.4% patients felt oral discomfort as a risk and only 34.4% of patients have poor adaptation to dentures. 32.6% of patientsdon't know the reason and didn't feel necessary to undergone treatmentafter tooth loss.

After Extraction

After 3 months of tooth extraction, all the patients were recalledfor the second evaluation. Table.4 shows only 53 patients had undergone prosthodonticrehabilitation on the second evaluation. 28.7% of patientsrestoredtheir teeth in the posterior region and only 16.8% in their anteriorregion. The demand for treatment was greater in the upper arch(30.7%) with small extension (34.7%) and single (32.7%) edentulousspaces.

After 3 months of interval of extraction, 51.5% of patients donotperceive any difficulty in chewing food. Most of the patientsperceived that tooth loss does not worsen the digestion, generalhealth and appearance of the patient, of about 72.3%, 67.3% and 58.4%respectively. 54.5% of patients perceived that they are not satisfiedwith their dental condition and 57.4% of patients concern about theirdental condition. Hence, 57.4% of people believed that prosthesissolve all the problems caused by tooth loss. Even though 50.5% ofpatients considered immediate replacement is necessary and 61.4% ofpeople believed that prosthesis does not have potential risk, 51.5% ofpatientsdo not seek immediate replacement of teeth.

Table 1. Initial clinical characteristics of patients and edentulous spaces (ES) at the time of teeth extraction.

	n	%
All Patients (n=101)		
Presence of prior ES		
Yes	92	91.1%

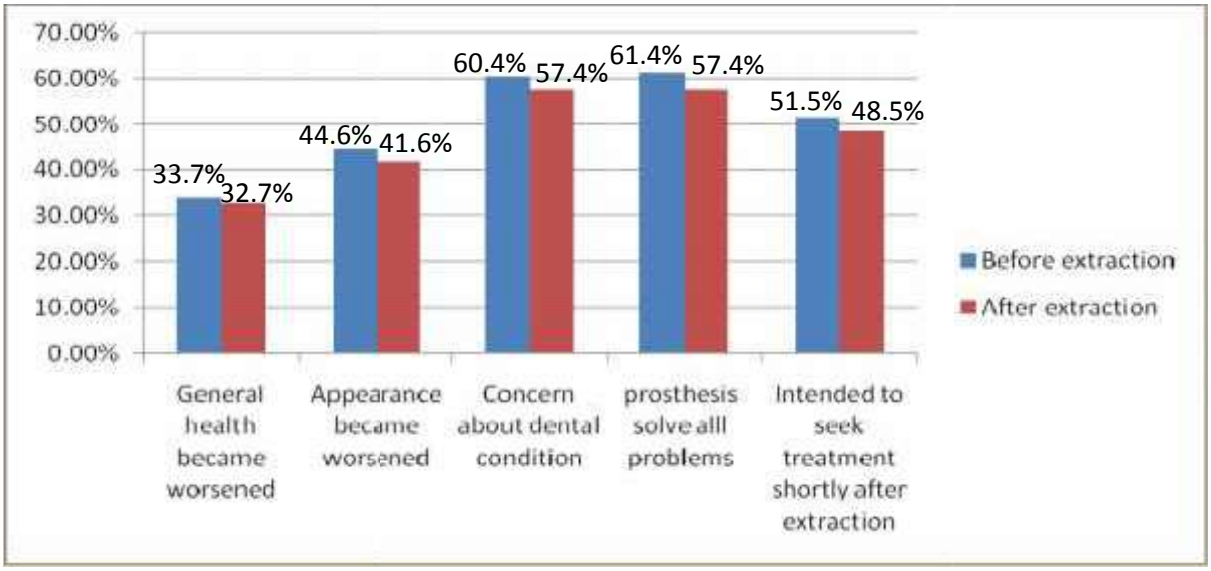
Graph 1: Comparison of self-perception of patients at the time and after teeth extraction.



Discussion

Decrease in self-perceived prosthodontic needs in patients has determined effect on oral health related to quality of life and measures [15, 16]. Hence, patients should understand the potential impacts of tooth loss. This study assess the patients self perception of prosthodontic need during and after extraction. The self perception of patient's impacts was higher at the time of extraction from 33.7% to 61.4% than after 3 months interval of extraction. Almost

half of the patient's undergone prosthodontic treatment of edentulous spaces at the time of extraction and after extraction. Most of the patients preferred fixed prosthodontic treatment. Before extraction, 52% of patients are satisfied with the dental condition and 54% of patients were not satisfied with the dental condition. Most of the patients believed that tooth loss does not affect the digestion, General health and appearance before and after extraction. Their result was in-accordance with the previous studies by Lineia Tavares.et al in 2007 [17]. Even though patients believed that prosthesis solve all problems and does not have potential risk, only half of the patients considered immediate replacement are necessary before and after extraction. Intention of prosthodontic need was greater only at the time of extraction. It is in accordance with the study by Trovik et al [18]. The patients believed that aesthetics and better function as the benefit of prosthodontic treatment whereas oral discomfort and adaptation to dentures as the risk. The patients are more reluctant and don't feel necessary to treat edentulous spaces. This result was not in accordance with the previous study by McGrath and Bedi [19]. It may be because of poor knowledge about the impacts of tooth loss and socio economical status of the patients [20].

Conclusion

Self- perception about tooth loss and prosthodontic needs at the time and after an interval of 3 month from extraction didn't have much significant change among patients. Better function and oral discomfort were mentioned as major benefit and risk of prosthesis. Treatment demand was low due to lack of knowledge and awareness, poor interest and motivation.

Abstract

Introduction: Dental patients with generalised anxiety where treated with nitrous oxide sedation method to reduce the anxiety level. The use of premedication before proceeding nitrous oxide sedation will fasten the onset of sedationDental fear and anxiety is a common problem in pediatric patients. There is considerable variation in techniques used to manage them. Various sedation techniques using many different anesthetic agents have gained considerable popularity over the past few years. Children are not little adults; they differ physically, psychologically, and emotionally. The purpose of this review is to survey recent trends and concerning issues in the rapidly changing field of pediatric sedation. We will study the topic from the perspective of an anesthesiologist. It will also provide information to practitioners on the practice of conscious sedation in dentistry and will also outline the route of administration, pharmacokinetics, and pharmacodynamics of various drugs used.. Knowledge about the post-operative care and management of post-operative complications are needed for the post care of the proper procedure.

Materials and Methods: Questionnaire were framed regarding suggestion of the drug, its usage, preferred route of administration,common complications encountered and circulated among the dentist and postgraduate students.100 dentist and postgraduate students participated in the questionnaire survey and they gave their opinion regarding the premedication and post operative complication of conscious sedation based on their clinical experience.The data collected from these 100 dentist and post graduate students of the same department were then statistically analysed to generate appropriate results regarding the questionnaire study.

Result: Based on the statistical analysis,60% of the dentist assure that premedication is safe for conscious sedation,whereas 20% of the dentist and post graduates state that only after proper history and other have no awareness about premedication for conscious sedation.

Conclusion: Over view of this survey is about the knowledge of premedication and post-operative complication towards dentist,since dentist practise in their clinicare aware about the premedication of conscious sedation and the survey shows that dentist have knowledge about the premedication and post-operative complication of conscious sedation.

Key Words:*Conscious sedation uses, Premedication, Post-op complication, Nitrous oxide and Midazolam.*

Introduction

Current understanding of pediatric oral health includes absence of dental fear and anxiety as well as healthy oral structures with the aim of forming the basis for good oral health throughout life. This implies two main dimensions in pediatric oral care which is to keep the oral environment healthy and to keep the patient capable of, and willing to utilise the dental service.[1]Dental anxiety can be managed either by non-phamacological methods like behavior therapy, desensitization or by pharmacological means that include conscious sedation techniques using inhalation sedation (nitrous oxide/oxygen mixture), oral or intranasal sedation (midazolam), intravenous sedation (midazolam) and general anaesthesia. The goal of conscious sedation is to alleviate fear and anxiety in order to facilitate treatment and it serves only as an adjunct to behavioural shaping techniques, and not a replacement.

It is widely recognised that the level of caries in children of various nations has dropped substantially over the last few decades[2].Unfortunately a significant proportion of these children still have caries which remains untreated.This represents a significant problem, if dentine caries is left it will usually lead to pain and sepsis which can often only be managed by extraction or extensive restoration of the affected teeth[3]Either conscious sedation or pre-medication with pharmacological agents is often recommended to children who are particularly fearful or anxious or for whom a disability prevents their being able to cooperate ,during the dental treatment.[3]The treatment and alleviation of pain is a basic human right

that exists regardless of age and demands treatment for this reason alone. Therefore all children should expect painless, high quality dental care.[4].

Sedation is required for some pediatric patients in order for the dentists to be able to deliver high quality, pain-free dental care. Sedation is used for pain control in form of local anesthesia, and for behaviour management [4]. Sedation is the production of a depressed state involving a lack of total consciousness. In sedation, the protective pharyngeal and laryngeal reflexes are not dulled, so the patient can maintain his or her own airway. In this sedated state, the functional activity of the higher centre of the central nervous system isreduced without distortion of the vital functions. The aim of this study is premedication and post-operativecomplications in conscious sedation.

Result:

Table 1: Premedication is safe for conscious sedation

Agree	After proper history	No	No idea
60%	20%	0.9%	9.1%

Table 2: Choice of drug for premedication

Anti emetics	Sedative	Antibiotic	Anticholinergic
75%	20%	15%	2%

Table 3: Major outcome of premedication

Fast onset of sedation	Post operative easiness	Both	None of the above
60%	23%	15%	2%

Table 4: Route of administration for conscious sedation

Inhalation	Intravenous

98%	2%

Table 5: Drug for conscious sedation

Nitrous oxide	Midazolam	Ketamine
95%	3%	2%

Table 6: Postoperativecomplications

Nausea	Vomiting	Post operative sleepiness	Diffusion hypoxia	Hypersensitivity
55%	25%	15%	3%	2%

Discussion

The majority of studies involved sedation in children less than 6 years of age, because this age range belongs to a 'pre-cooperative' group. Treatment needs and management of children will vary as they grow and develop[5].Overall goal of premedication of conscious sedation in pediatric dentistry is to provide a pain free treatment and to relieve the fear and anxiety of the pediatric patients so that the patient feels comfortable in the dental environment and willingly comes back to the clinic for regular checkups without any reluctance[5].The premedication of conscious sedation could increase the success rate of the treatment with ease of operation for the dentist while performing the dental procedure[6].Based on the statistic analysis,60% of the dentist assure that premedication is safe for conscious sedation,whereas 20% of the dentist and post graduates state that only after proper history and other have no awareness about premedication for conscious sedation.(Table 1), A.L. Halosthane survey 95.6% dentist have said that only after proper history of the patient Premedication can be given but in this survey 60% of the dentist agree with premedication is safe for conscious sedation. Drug of choice for premedication is sedation,anti emetics, antibiotic and anticholinergic among this anti emetics is widely preferred drug for premedication which is of 75%, next choice of drug is sedation which is 20%whereas antibiotic and anticholinergic is of 3% and 2% which is less used drug for premedication(Table 2). In Hosey F.G survey most commonly used drug of choice is nitrous oxide with opioids midazolam to increase the concentration.Based on

statistic analysis of major outcome for premedication among dentist and post graduate is 60% fast onset of sedation,23% post operative easiness,15% both whereas 2% have no awareness about major outcome of premedication(Table 3). The Most prevalent route of administration of the sedative drug used. 98% of the drug was administered by inhalation method whereas 2% of the drug was administered by intravenous route. The dentist also mentioned that during administration of the drug assistance from specialised anesthetist was also taken so that to increase the efficacy of the sedative drug and to maintain thevital signs of the patient in a safer manner(Table 4). Based on the statistical analysis,95% of the dentist and the postgraduate students prefer nitrous oxide for conscious sedation during their dental treatment.It is most commonly used drug and it is preferred by large number of the dentist population. 3% of the dentists prefer Midazolam to control their pediatric patients, whereas 2% of them prefer ketamine for conscious sedation in pediatric patients.(Table 5).Post operative complications in conscious sedation is nausea,vomiting,hypersensitivity,diffusion hypoxia and post operative sleepiness in this 55% nausea is the common post operative complication of conscious sedation next common most complication is vomiting which is 25% and others 15% post operative sleepiness, 3% hypersensitivity,2% diffusion hypoxia is less common post operative complication of conscious sedation(Table 6)

Routes of administration Oral Midazolam is the most commonly used oral agent. It produces earlier sedation, more complete amnesia and improved awakening when compared with diazepam. The onset is 60- 90 seconds and the duration of action for small doses is 10-15 minutes. Oral sedation is easy to administer and monitor, and it costs less. But the level of sedation cannot be easily changed and there is no analgesic effect. Inhalation It is a dependable and simple route of drug administration. As a general rule, the drugs delivered through this route have a very rapid onset and short recovery period[7]. Their effect may be rapidly reversed by lowering the concentration of the agent or discontinuing it entirely and administering only oxygen or room air.Nitrous oxide is the most popular agent used through this route. But it has an inherent disadvantage of being the weakest agent available today. Nitrous oxide administration requires special equipment and training. Although it has a wide safety margin, it could prove dangerous and sometimes even fatal at the hands of an untrained individual. Parenteral administration Intravenous sedation The standard technique is the use of titrated dose of a single benzodiazepine or opiod, like fentanyl, etomidate and propofol. The actions can be reversed by using agents like naloxone, a competitive antagonist of

opiodreceptors and flumazenil, a pure benzodiazepine antagonist[7]. Other routes include intramuscular and subcutaneous administration. But they are not commonly practiced.

Nitrous oxide

It is a gas and used as the inhalational anesthetic agent. It has anxiolytic and sedative properties with varying degree of analgesia and muscle relaxation. Recent studies suggest both gamma-aminobutyric acid type A (GABA A) and N-methyl-D-aspartate (NMDA) receptors are affected[8]. It has a long history of safe use providing moderate sedation for minimally moderately painful procedures. Care must be taken when used in addition to other sedatives where deep sedation can easily result. Currently, available nitrous oxide/oxygen delivery systems are manufactured with oxygen fail-safe devices that stop the flow of nitrous when the flow of oxygen is stopped, thus preventing this catastrophe. It should be the first choice for pediatric dental patients who are unable to tolerate local anesthesia alone and have sufficient understanding to accept the procedure[8]. It may be offered with mild to moderate anxiety to better accept the treatment which may require a series of visits. It can also facilitate the provision of more complex time-consuming procedures and dental extractions particularly for young and anxious patients undergoing orthodontic extractions.

Ketamine

It is a dissociative agent, which makes a state of catalepsy that gives sedation, control of pain and amnesia. Ketamine has advantages over other drugs in its relative cardiovascular steadiness and restricted affect on the respiratory mechanics. Recovery occurs in 30–120 min, which allows for patient discharge in a reasonable time after the procedure. It is a dose-related cardiovascular stimulant. Even in children with congenital heart disease, it caused clinically only minor increases in heart rate and mean pulmonary artery pressure during catheterization. More than 11,000 reported cases of its use in children with no reported fatalities have been described in the literature by Green. The most frequently cited disadvantage is the emergence phenomenon, seen more commonly in adults (5–50%) than children (0–5%)[9]. Ketamine causes an increase in salivary and tracheobronchial mucus gland secretions, so an antisialogog is recommended for use with ketamine for GA.Emesis is the third most common side effect of ketamine. In Green's review, he found that the reported incidence of vomiting in children was 10%, and was associated with dental

procedures..Ketamine can be given intramuscularly at 3–4 mg/kg or intravenously at 1–2 mg/kg.

Benzodiazepine

They provide anxiolysis, sedation/hypnosis, skeletal muscle relaxation, anterograde amnesia, respiratory depression, and an anticonvulsant effect[10].but have no analgesic properties. Mechanism of action is through GABA-mediated opening of chloride channels. Benzodiazepines (BZD) have a wide margin of safety between therapeutic and toxic doses. They have high lipid solubility so have a rapid onset of action[11]. They have been widely used in dentistry. They are usually combined with nitrous oxide/oxygen for conscious sedation as additive effect of nitrous oxide to BZD produces analgesic properties.[12] The most common drug used is midazolam, which is having a short duration of action. It is considered as BZD of choice for conscious sedation during treatment in pediatricdentistry.It is given in the form of sweetened syrup given either via a drinking cup or drawn in a needleless syringe and deposited in the retromolar area or oral tablets[13].

Propofol

It is a water-immiscible oil which is formulated as an emulsion with a soya oil base to facilitate injection[14]. The elimination half-life is between 2 and 24 h. However, its duration of clinical effect is much shorter because Propofol is rapidly distributed into peripheral tissue, and its effects, therefore, wear off considerably within even a half hour of injection. This, together with its rapid effect and the moderate amnesia it induces makes it an ideal drug for IV sedation.Sub-anesthetic doses of propofol used for IV conscious sedation infusion facilitated operative dental treatment in anxious children[15]. IV induction by ketamine or propofol remains a problem because of the difficulty in obtaining vascular access in the awake and frightened child. Potent volatile anesthetic agents are used for induction of anesthesia to avoid the struggle to get IV access before the child is asleep[16]. In a study by Arya and Damle in comparison of propofol with midazolam it was found that propofol exhibit rapid onset while having involuntary movements as side effect while midazolam had an edge over propofol in being good anxiolytic and anticonvulsant. With sevoflurane, dose of propofol used is an initial loading dose, (usually 1 mg/kg body weight) and the maintenance dosage needed to achieve satisfactory sedation, ranging from 0.3 to 4 mg/kg/h[17].

Complications in Conscious Sedation

Surgical Factors

As airway is shared by the anesthesiologist and dentist, it may be soiled with blood or debris and stimulation of trigeminal nerve increases chances of arrhythmia during surgery.

Pediatric Issues

1. They may have enlarged tonsils and adenoids thus increasing chances of respiratory obstruction
2. They are uncooperative and communication may be challenging
3. Many medical conditions can co-exist such as epilepsy, reflux, and cardiac anomalies
4. They are needle phobic and highly anxious
5. High autonomic activity thus increasing chances of arrhythmias and vasovagal response
6. Gastric emptying may be delayed
7. Problems of ambulatory anesthesia.

Keeping all the above factors, one should thoroughly prepare the patient after complete pre-anesthetic check-up and after proper examination of airways, cardiorespiratory system, and any congenital abnormalities. Another one of the most important problems is position in the dental chair[17,18,19]. It becomes very difficult to resuscitate the patient if something unwanted happens suddenly[20]. All types of drugs and resuscitative measures should be there in case of any emergency.

Current Status of Conscious Sedation in Pediatrics

Sedation for dental procedure carries high risks for both patient and anesthesiologists. The sedation techniques offer alternative for patients where the use of general anesthesia (GA) is unavoidable.[21] Oversedation or undersedation is unreasonable or unacceptable in some circumstances.[22] In order to decrease dependency of the patient to sedation other psychological methods can be used, e.g. Cognitive reconstructing, hypnosis, relaxation and distraction techniques, systematic desensitization, and conditioning

Conclusion

Over view of this survey is about the knowledge of premedication and post operative complication towards dentist,since dentist practise in their clinicare aware about the

premedication of conscious sedation and the survey shows that dentist have knowledge about the premedication and post operative complication of conscious sedation.

Abstract

Introduction: Dental anxiety affects a significant proportion of people of all ages from different social classes.It remains to be a serious concern for both dentists and patients for the provision of routine dental care on day to day basis.Anxiety and fear towards dental treatment are common problems frequently experienced by adolescent patients. Occurrence of dental anxiety has attributed to factors like personality characteristics; traumatic dental experiences in childhood, vicarious learning from family members anxious to dental treatment, blood injury fears and pain reactivity.To determine the prevalence and predictive factors of dental anxiety among adolescent patients attending a dental hospital

Materials and Methods: A pretested, interview administrated questionnaire was used among 50 adolescent patients, attending the pedodontic clinic of Saveetha Dental College, Chennai. Descriptive statistics were computed using frequency, inferential statistics were done using Chi square test.

Results: Total of 50 participants completed the questionnaire. Out of 50, 24(48%) were males and 26(52%) were females. Comparing the genders, dental fear was high in female patients 25(50%), and it was high after treatment under local anaesthesia28(56%) and for patients who had appointment within last year 33(66%).

Conclusion: Analysing the results of the study, it can be concluded that factors like, number of previous dental treatments,post traumatic dental experiences, personality, gender, age and education level significantly affected dental anxiety. Dentists attending such young patients should bear all these factors in mind, to provide a quality treatment which will be totally acceptable by the patient.

Keywords: *outpatients, anxiety, phobia, traumatic experience, adolescents*

Introduction

Anxiety can be defined as a state of unpleasantness associated with fear of danger from within or a learned process of one's own environment. It depends on the ability to imagine[1]. Dental anxiety has been mainlyassociated with poor oral health.Avoidance of the dental treatment was high in anxious patients and they also had increased caries rate and DMFS scores. The long-term consequences for the dentition explains about the role of dental anxiety which leads to increased in usageof antibiotics and analgesics[2].

Dental anxiety is defined as state of anxiety as it occurs due to the dental treatment procedure and it is related with negative expectations which are often linked to earlier traumatic experiences, negative attitudes in the family, fear of pain and trauma and perceptions of an painful previous dental treatment. Anxiety is one of the most common problems encountered in the dental operatory and it is a challenge for the Paediatric Dentist, as many children who are extremely anxious totally refuse the dental treatment[3].

Dental anxiety is defined as "an abnormal fear or dread of visiting the dentist for preventive care or therapy and unwarranted anxiety over dental procedures" and may have psychological, cognitive and behavioural consequences. Dental anxiety can prevent patients from cooperating fully during dental treatment[4]. Moreover, anxious people tend to overestimate pain and discomfort caused by dental treatment and may also postpone or miss appointments, with negative consequences for their oral health and often having to incur more complex interventions, thereby entering a vicious cycle that tends to intensify anxiety with regard to treatment[5].

Dental anxiety is a common problem that affects people of all ages and appears to develop mostly in childhood and adolescence. Childhood dental anxiety is not only distressing for the child and family but is also associated with poor oral health outcomes and an increased reliance on costly specialist dental services.Thus, the frequency of dental diseases and unpleasant dental experiences is greater among children with more anxious and uncooperative behaviour in comparison to non-anxious children[6].

Dentists need to understand the anxiety and its repercussions in dental care and need to know how to identify behaviour that indicates anxiety so that a relationship of trust may be established with the patient for the implementation of strategies aimed at minimising the anxiety caused by dental treatment.Questionnaires or scales constitute the most common means of assessing dental anxiety. [7], [8]

Although the aetiology of dental anxiety in children is still not completely understood, it has been a subject of concern for countless researchers over numerous years[9]. Anxiety is “a multi-system response to a supposed threat or danger; it comprises a combination of biochemical changes in the body and aspects of the patient's personal history, memory and the social situation”[10]. “Dental anxiety is associated with symptoms that include at least four of the following: palpitations, sweating, trembling, shortness of breath, sense of choking, chest pain, nausea or other stomach upset, dizziness, a feeling of being detached from the world, being unable to think, fear of dying, numbness or tingling, cold or hot flushes, easily tired, trouble concentrating, irritability, muscle tension, restlessness, and sleep problems”[11].

Dental anxiety is expected to start during childhood and increase over time in the absence of diagnosis and management[12]. This anxiety is relatively common in the dental setting: “the British national children's dental health survey found that the proportion of children who were dentally anxious steadily increased through the primary school years and then levelled off during the secondary school years to about 50% of the population”[13]. “A study of eight European countries found that 35% of 5-year-olds and 21% of 12-year-olds were fearful before visiting the dentist, whereas 48% of children in Dubai were anxious even before visiting the dentist”[14]. Most people feel that their dental fears began in childhood[15].

The disturbing natures of some dental procedures could be considered as the supreme anxiety-provoking stimuli[7]. A study in 2002 found that children with many carious lesions at the age of five years are likely to be dentally anxious at 10 years of age, probably because they have had pain and other negative treatment experiences[15]. Dental anxiety is the basis of avoiding dental visits, as reported by numerous studies[16]. Furthermore, dental anxiety has been reported to decrease with repeated exposure to dental treatment, possibly due to habituation.

Negative thoughts were associated with patients with dental anxiety; anxious and calm patients were found to differ dramatically on a sum of other cognitive reasons[14]. Anxious patients are supposed to be less capable of continuing treatment plans that could help to reduce the anxiety during dental treatment; they expect “dental treatment to be more painful and more traumatic, they expect themselves to be more difficult to treat, and expect to be more nervous and helpless”[13]. Several studies reported that dental anxiety is more prevalent in females than in males[17]. Consequently, the objective of this study was to assess dental anxiety and the potential causative factors in a female population.

The prevalence of dental anxiety among children varies according to the methodology employed and the age of the subjects. A study with Taiwanese children aged 5-8 years found a 20.6% prevalence rate of dental anxiety[9]. Dental anxiety can be considered a common condition, affecting approximately 9% of children and adolescents in Europe and in countries such as Australia, Canada and the United States [10].

In a study by Ost, it was reported that almost 20% of dental phobic were in the age group of 14[18]. similarly, Milgrom reported that 33.3% of the individuals whom he studied, became anxious during adolescence [19]. The nature of dental anxiety is more often related to age of onset; and it is believed that child-onset are more often due to past traumatic dental experiences and the later-onset are more likely to be constitutional vulnerability to the anxiety disorder [20].

Voluminous work has been conducted, correlating fear, anxiety and dental treatment. But the age group between 10 – 17 years has not been studied much in a hospital environment in India. Hence this study was planned to conduct in outpatients attending Pedodontic O.P of Saveetha Dental College in Chennai. Once the prevalence and predictive factors for dental anxiety are listed out, it would help the clinician to execute a tailored intervention and behaviour management for each patient.

Materials and Methods

Study Design: An observational study

Study Area: Pedodontic outpatient clinic, Saveetha Dental College, Chennai, Tamil Nadu.

Study Population: Adolescent patients aged between 10 to 17 years visiting the hospital were included in the study

Inclusion Criteria: Patients attending the O.P during the scheduled days of the study, who were in the designated age group, those who were willing were included in the study

Exclusion Criteria: Patients who had already participated in similar studies. Participants who dint produce a written informed consent were excluded from the study.

Survey instrument: A pretested, interview administrated questionnaire was circulated among 50 adolescentpatients visiting pedodontic outpatient clinic i.e.24 male children and 26 female children, age of 10 to 17 years, who visits saveetha dental hospital. The 7 item questionnaire was designed to elicit the prevalence and predictive factors regarding dental anxiety.

Scheduling: Data collection was scheduled for a period of one week.

Sample and Sampling methodology: Sample size was calculated based on the study by Arshia [22] at 80% power and 5% alpha. A convenience sampling methodology was adopted.

Statistics: Data was entered using micro soft excel. Descriptive statistics (frequency and percentage) were used to project the results

Results

Out of the 50 patients who participated in the study, 26 (52%) were females and 24(48%) were males. 22(44%) belonged to the age group 10 – 13 years and 28(56%) belonged to the age group 14-17 years.

Table– 1- Gender wise predictive factors for causing dental anxiety among study subjects

Factors responsible for Dental anxiety	Yes		No	
	Male n (%)	Female n(%)	Male n(%)	Female n(%)
Fear unrelated to dentistry	1(2)	5(10)	43(86)	1(2)
Previous dental treatment with	32(64)	8(16)	2(4)	8(16)

local anaesthesia				
Present dental treatment with local anaesthesia	20(40)	8(16)	17(34)	5(10)
Dental appointment within last year	20(40)	13(26)	10(20)	7(14)

Table – 2- Degree of Dental Fear among Study Subjects and Their Parents

	High		Low	
Parent's dental fear	40%		20%	
Children's dental fear	Male n(%) 10(20)	Female n(%) 25(50)	Male n(%) 5(10)	Female n(%) 10(20)

Discussion

Current study had totally50 respondents, 24 were males and 26 were females,the response rate was 80%. In our study 30% of the adolescents have high degree of dental anxiety, where as in the study by Krista Baier [21]20% of the children had high dental fear. This discrepancy could be due to the difference in type of and number of invasive procedures undergone by the study subjects in both studies.The children and adolescents were most often accompanied by their mothers during dental care (87%). Maternal dental anxiety is likely to be associated with the avoidance of dental treatment, which could prevent children/adolescents from receiving appropriate dental care[20].This aspect gains further importance when considering the fact that women exhibit higher levels anxiety than men and are generally in charge of accompanying their children in health-related matters.

The tendency toward an association between the need for invasive treatment and the anxiety scores of children and adolescents regarding dental treatment (P = 0.08) demonstrates that, even with the progress gained in minimally invasive dentistry, the use of local anaesthesiaremains closely associated with unpleasant experiences regarding dental treatment and dental anxiety [21],[22].

Fear reported by other family members is one of the factors most often associated with dental fear and anxiety in children. Indeed, negative attitudes and experiences transmitted by mothers and their opinions regarding dental treatment are considered etiological factors of dental fear and anxiety in children.A previous study found that children whose mothers exhibited a moderate or high level of dental anxiety were more likely to have untreated dental caries in comparison to children whose mothers had a low degree of dental anxiety.

When dental anxiety prevalence and gender was taken in to consideration. Our study results were in agreement with other studies [22]. In the current study 12% of the adolescents had phobia unrelated to dentistry, this was in contrast and lower when compared to the study by Corah NL [23]. The difference could be due to the difference in culture, geographical variations and socio demographic factors between the study populations.

In our study, children who received treatment under local anaesthesia behaved negatively 4 times higher than those who dint receive treatment under local anaesthesia. This was twice higher than the study results by Nakai [24]. Children who had painful experience at an early age are an important factor related to the dental anxiety.In our study we found that children with previous dental experience had significantly has dental fear than those without. This result was in accordance with the study byNicolas [25].Dental fear or anxiety may be described as a subjective state of feeling or reaction to a known source of danger which lies in the subconscious mind [14]. The most commonly reported source of fear in the present study was ‘fear of specific stimuli’ mainly pain, while other categories such as fear of catastrophe, fear of reprimand for neglect of oral hygiene and generalized fear cause less concern to the surveyed children. Such fear of pain may be a major obstacle to seeking dental care [15] and appears to be strongly associated with extreme deterioration of oral and dental health [16]. The finding that painful dental experiences and expectations of trauma were identified as the major sources of adverse reactions to dentistry in other reports [12, 17].

Another interesting finding in the current study was that, there was an association between the type of treatment done in the first dental visit and dental fear scores in the second dental visit. This was again in accordance with the study by Nicolas [25].

Despite the results obtained from the current study, it carried few limitations in terms of sample selection and sample size, making the results non generalizable to whole adolescent population. Hence a study on larger sample size with a probability sampling technique will ensure generalizable result, which can be used in evidence based practice.

Conclusion

Despite technological advances in modern Dentistry, anxiety and fear are common among children and adults, constituting a significant barrier to dental care, interfering with regular oral health care.Fear is part of childhood development. It is usually transitory and does not produce major disruptions in child's daily life. Fear can generate anxiety, which, in turn, can be defined as a response to a situation in which the source of a threat to the subject is not clearly defined. Although the ability to experience fear is an innate biological function,fear responses to certain objects and situations are mostly acquired through learning.Fear and anxiety can make it difficult, at different levels, for performing children dental treatment, creating an atmosphere of tension for both the dentist and their patients. It can also result in an unsatisfactory treatment or even prevent its fulfilment. Anxiety and dental fear are considered multifactorial conditions; there are several variables that can influence these conditions, such as family interference, socioeconomic factors, age, child's temper, among others [1,8,13,23]. However, few studies assess, in the same group of people, the relationship between fear and anxiety among children and their caregivers, as well as the caregiver's prediction of fear and anxiety experienced by children during dental treatment.

Based on the results of the study, it can be concluded that females have more dental anxiety than male patients and its occurrence is dependent on so many factors like, personality, traumatic dental experiences in child hood, vicarious learning from dentally anxious family members, pain reactivity and etc.

Abstract

Introduction: Chronic Fatigue Syndrome also known as Myalgia Encephalomyelitis is a neurological illness. It is a condition that presents long term physical and mental fatigue with associated symptoms of pain and sensitivity across a broad range of systems in the body. The etiology is unknown. The aim of this study is to estimate the prevalence of Chronic Fatigue Syndrome(CFS) in students and relate the incidence to various factors such as sleep, rest, relaxation, diet using a questionnaire .

Materials and Methods: Questionnaire will be prepared using the established factors affecting Chronic Fatigue Syndrome in students of age group of 19-24years will be included in this study. Those who are not willing to participate will be excluded.

Result: The survey found that 49 out of 100 participants are not aware of Chronic Fatigue Syndrome. It is important to know about CFS which helps to reduce the prevalence.

Conclusion: Chronic fatigue is one of the most Perplexing conditions in the domain of medical science.People with CFS who have a thorough knowledge of the illness tend to manage their condition better and have a more positive outlook. Whereas, people in general are not aware of this condition and it is important to know about CFS which helps to reduce the prevalence. Several studies have described how living with a chronic invisible illness results in a multiplicity of stressful consequences and considerable impact on daily life

***Key Words**: fatigue, stress, symptoms, health, illness.*

Introduction

The chronic fatigue syndrome is a clinically defined condition characterised by severe disabling fatigue and a combination of symptoms that prominently features self-reported impairments in concentration and short-term memory, sleep disturbances, and musculoskeletal pain. The extent to which the features of the chronic fatigue syndrome are generic features of chronic fatigue and deconditioning due to physical inactivity common to a diverse group of illnesses must also be established[1,2].

The onset of the condition is usually sudden. is means that the main symptom of fatigue (along with other symptoms) may appear only from a particular point of time before which they did not exist. The onset is usually preceded or accompanied by a " u-like" disease, quite similar to a common cold or viral infection. is has promoted the association of virus and viral infection with the etiopathogenesis of the disease with the postulation that such viral infections somehow cause meningoencephalitis resulting in CFS. Both pathogenic as well as nonpathogenic viruses are sought to be associated with the etiopathogenesis of the disease.In some cases, the onset of the disease follows a prolonged period of adverse stress. The period of stress may be of several months duration and this stress can be either physical or mental, or both. Some authorities consider these as precipitating factors whereas some consider them as actiological factors. The main symptom is fatigue or exhaustion. The fatigue is always of new onset which means that it was not present to any significant degree in the past. The duration of the fatigue is prolonged and to qualify as CFS it must be of more than 6 months duration. The fatigue is usually unexplained. It cannot be attributed to any known or immediate cause. It is not directly related to exertion. It is not as a result of physical exertion, but physical exertion always exacerbates it.It is not significantly relieved by rest unlike the usual fatigue that follows exertion. The level of fatigue is such that it causes significant reduction of previous activity levels of the person.Chronic unexplained fatigue unrelieved by rest that incapacitates the patient is the hallmark of CFS.Pathophysiology of CFS is largely unknown at the present moment. ere are no diagnostic laboratory tests for CFS. In fact, no abnormal lab findings characteristic of CFS has been identified so far. There are two hypotheses which explains the Pathogenesis of CFS which includes two categories: a) Biomedical

abnormality, oxidative stress, genetic predisposition, infection by viruses both pathogenic and non-pathogenic, infection by bacteria, immune dysfunction b)Hypothalamic pituitary adrenal axis abnormality, psychological factors, psychosocial factors.

Evidence of viral infection with cause and effect relationship has not been found in CFS so far. Similar is the cause of bacterial infection. But that an inflammatory (may not be infective or postinfective) condition exists along with CFS has been surmised from such findings as arthralgia, myalgia, u-like prodrome and tender lymphadenopathy.The role of oxidative stress in CFS is an emerging focus of research. Although it is uncertain whether oxidative stress is a cause or a result of this illness, recent studies have demonstrated that oxidative stress contributes to the pathology and clinical symptoms of CFS. Theoretically, oxidative stress can be caused by an increase in the generation of reactive oxygen species, of which mitochondrial dysfunction is believed to be a main source, or it can be caused by a decline in the efficiency of antioxidant enzyme systems. Recent studies have examined both of these possibilities by looking for markers of oxidative stress and protective antioxidant systems[3]. To identify theprevalence of chronic fatigue is critically essential andimportant in theprocess of chronicfatiguetargetingstudies andtherapeuticdevelopments.Thisstudy aimed toreviewthecurrentstudiesfortheprevalenceof Chronic Fatigue Syndrome among dental graduates[4].

Methodology

Study Design

In order to compare the features of prevalence of chronic fatigue syndrome, among dental graduates,questionnairewas prepared using the established factors affecting this syndrome in students of age group of 19-24yrs. A total of 100 students (convenience sampling) participated in this research of which 42 were males and 58 were females.

Gender-
Age-
Weight-
Height-

1. What are your views on chronic fatigue syndrome?
A) Complex disorder characterised by profound fatigue that is not improved by bed rest
B) Severe fatigue lasting at least 6 months
C) Significant impairment of short-term memory or concentration
D) All of the above

2. .Have you experienced fatigue or tiredness for a prolonged period of time (6 months or more) despite adequate rest and not working overtly hard?
Yes / No

3. How long ago did your problem with fatigue begin?
Less than 6 months / More than 6months / Not having a problem with fatigue

4. Do you currently have a diagnosis of chronic fatigue syndrome(CFS)?
Yes / No

5. Have any of your family members been diagnosed with CFS?
Yes / No

6. I am prone to pimples.
Yes / No / In between

7. Do you have difficulty in concentrating?
Often / Sometimes / Hardly ever

8. I am unable to work full-time.
True / Uncertain / False

9. I am frequently irritable.
True / Uncertain / False

10. Do you feel unrefreshed after sleep?
Yes / No

11. Do you experience headaches?
Often / Sometimes / Hardly ever

12. Do you experience muscle pain?
Often / Sometimes / Hardly ever

13. How frequently do you get sore throat?
Often / Sometimes / Hardly ever

14. Burning sensations in the face, hands or feet.
Yes / no / uncertain

15. Do you feel dizzy when sitting up or standing?
Frequently / occasionally / hardly ever

16. I react badly to. Many chemicals / few chemicals / hardly any chemical

17. How many hours do you sleep daily?
8hours / more than 8 hours / less than 8 hours

18. Are you currently engaging in any form of exercise?
Yes /no

19. Have you ever consulted a medical doctor about your fatigue/energy problem?
Yes / no

20. Do you currently have a medical doctor overseeing your fatigue problem?
Yes / no

21. Are you currently taking any medications for CFS?
Yes / no. If yes.what medicines are you taking?

Figure 1: Questionnaire

Data Analysis

The main objective of this research was to explore and identify the main experiences of CFS for the individual sufferer. The research aimed to explicate the major experiences and events core to the experience of CFS in order to enable psychologists and counsellors to more richly understand the illness effects. 10% of the people have reported that they have muscle pain or myalgia, because of the similarity of symptoms, fibromyalgia and CFS are considered to be overlapping syndromes. In fact, CFS can affect people of any gender, age, race, or socioeconomic group. Only 12% of them are undergoing diagnosis for this syndrome. CFS is usually diagnosed by evaluating symptoms and eliminating other causes of fatigue. Unexplained continuing or recurring chronic fatigue for at least six months that is of new or definite onset, is not the result of ongoing exertion, and is not mainly relieved by rest, and causes occupational, educational, social, or personal activities to be greatly reduced. The survey found that 10% are suffering from Chronic Fatigue Syndrome with fatigue problem for more than 6months. 5% of the people are undergoing medical treatment and medical doctor overseeing this fatigue problem. For patients with CFS, learning to manage activity levels is a key part of managing the illness. This requires a new way of defining exercise and thinking about daily activities. 25% of them are engaged in doing exercise which can manage the illness. It's important, however, not to avoid activity and exercise altogether. Such avoidance leads to serious deconditioning and can actually worsen other symptoms. Sore throat is one common sign of Chronic Fatigue Syndrome. 26% of them reported that they frequently get sore throat. It is often accompanied by a feeling of tenderness in the lymph nodes in your neck. However, to be diagnosed with Chronic Fatigue Syndrome, symptoms must last for six months or more because sore throat is a symptom for many other illnesses. Headache is associated with many of these symptoms as well. This survey says 15% of the CFS patients reported that they feel less refreshed and restored after sleep than they felt before they became ill. Unrefreshing sleep can be present even though medications may help patients achieve required hours of sleep. A sleep specialist should evaluate patients whose sleep remains non-restorative following standard interventions. Memory and concentration complaints are two of the more distressing symptoms reported by people with CFS. Relaxation and meditation training and memory aids, such as organizers, schedulers, and written resource manuals, can be helpful in addressing cognitive problems. Some patients with CFS may also exhibit symptoms of orthostatic instability, in which symptoms are triggered or made worse by standing upright, in particular frequent dizziness and light-

headedness. The survey found that 10% of them feel dizzy when sitting up or standing. When clinicians judge these symptoms to be severe enough to warrant additional assessment, they should refer patients for evaluation by a cardiologist or neurologist. Specific treatment for orthostatic instability should only be started following confirmed diagnosis and by clinicians experienced in evaluating therapeutic results and managing possible complications.The reported incidence of acne contributes to the CFS which Is caused by inflammation and oxidative stress.

Result

The survey found that 49 out of 100 participants are not aware of Chronic Fatigue Syndrome. It is important to know about CFS which helps to reduce the prevalence.

DIAGNOSIS:

CFS can resemble many other disorders, it's important not to self-diagnose CFS. It's not uncommon for people to mistakenly assume they have chronic fatigue syndrome when they have another illness that will respond to treatment.Diagnosis is established through the exclusion of other diseases causing fatigue. This syndrome is rare in childhood and adolescence, although the fatigue symptom per se is quite commonin paediatric patients. Currently, no curative treatment exists for patients with chronic fatigue syndrome[5,6]. The therapeutic approachto thissyndrome requires a combination of different therapeutic modalities. The specific characteristics of the symptomatology of patients with chronic fatigue require a rapid adaptation of the educational, healthcare and social systems to prevent the problems derived from current systems.Despite the concerns of some medical professionals that diagnosing a patient with CFS could be unhelpful, this study revealed overwhelmingly that receiving a diagnosis was very positive for CFS sufferers[7,8,9].

Prevention and Management of Fatigue

It is important to manage fatigue in the context of each patient suffering with it. Treatment of CFS with its various major clinical and functional impacts, should be associated with a ‘biopsychosocial model’ of management. Educating patients about their diagnosis is crucial. Physicians should emphasise distinction among factors that may have predisposed patients to develop, trigger, or perpetuate the illness. Progressive muscular rehabilitation, combined with

behavioural and cognitive treatment, and appropriate choice of medications are essential parts or therapy.[10]Various treatment of CFS has been subjected to randomised controlled trials. However, recent reviews conclude that only cognitive behavioural therapy (CBT) and graded exercise therapy (GET) have a scientifically proven beneficial effect[11,12].Important components of CBT are explanation of pathophysiologic theories on CFS, challenging of fatigue-related cognitions and gradual increase of physical activity. In this way, simply speaking, the patients learn to acquire control over their symptoms.Management of CFS patients should also include attention to possible complications, like secondary depression and dietary deficiencies in the severely disabled. Further, patients need appropriate assistance on social and economical issues. Treatment modalities for patients with CFS are aimed at relief of symptoms rather than curing the disease[13,14]. Common pharmacologic therapies that may be prescribed by a physician include the administration of non-steroidal anti-inflammatory drugs (NSAIDs) for pain relief, low-dose tricyclic antidepressants to improve sleep and relieve mild pain, and anxiolytic agents to treat anxiety. In some cases, serotonin reuptake inhibitors prescribed to non-depressed patients have been found to be beneficial. Furthermore, evidence-based systematic reviews have illuminated the beneficial role of light exercise[15]. Aims of treatment are to reduce levels of fatigue and associated symptoms, to increase levels of activity, and to improve quality of life[16].

Discussion

Fatigue of the dentist is mainly caused by his forced working posture. Although several studies of the cause of the fatigue and its recovery way have been done, it seems that they are not practically applied to the dental field[17]. In this study authors obtained some basic information for the fatigue of dentists and analysed them in view point of the experience year and working posture of dentists.The chronic fatigue syndrome (CFS) is fundamentally characterized by intense fatigue of unknown cause, which is permanent and limits the patient's functional capacity, producing various degrees of disability. It is advisable to differentiate fatigue from other medical concepts with which the symptom is often confused: first, from asthenia, defined as the lack of strength or feeling of inability to carry out daily tasks, which is more intense at the end of the day, and usually improves after a period of sleep; second, from weakness, which is the reduction or loss of muscular strength, and the key symptom in muscular diseases. In addition to fatigue, CFS is associated to a

wide spectrum of symptoms, including arthralgia, muscle pain, headaches, anxiety, depressive symptoms, cognitive disorders, sleep disorders, or intolerance to physical exertion, among the most frequent[18]. CFS is sometimes seen in members of the same family, but there is no evidence that it is contagious; instead there maybe a familial predisposition or a genetic link.Studies suggest that close to 80 percent of people who are living with chronic fatigue syndrome have never been formally diagnosed and are not getting the treatment they need, but data also implies that getting a diagnosis early in the course of the disease before you've had it for two years gives you the best chance of improving your symptoms through treatment[19].

Research suggests that chronic stress is associated with deregulation of the neuroendocrine and sympathetic nervous systems causing changes in the immune system and consequently resulting in an increased risk of periodontal diseases, recurrent aphthous ulcerations, herpes virus in- fections, etc[20]. Moreover, it is known that chronic stress can mediate the risk of periodontitis through changes in health- related behavior, such as oral hygiene, diet and smoking[21,22]. There could be several explanations why the current study failed to find an association between oral hygiene and stress. First of all, our study did not aim to distinguish short-term stress from chronic stress. It is likely that students experienced short-lived stress related to the examination period. Short-term stress, as opposed to chronic stress, has a stim- ulating effect, possibly resulting in unchanged oral health- related behavior. Secondly, stress is often associated with perfectionist personality type[23]. A perfectionist person, especially in the field of dental studies, is self-conscious about personal oral health status and, therefore, such a person is likely to have sufficient oral hygiene habits.Unrefreshing sleep is extremely common in people with CFS. Patients usually report a longer time to fall asleep, an increased time in bed awake, and a broken and restless sleep pattern. A shift from regular night-time sleep to daytime naps and a late-night to late-morning sleep cycle is some- times noted. It is known that chronic disruption of the normal sleep pattern can induce symptoms in healthy volunteers, including fatigue, musculoskeletal pains, irritability and impairment of concentration.The general goals of sleep management are to establish a regular, unbroken, night-time sleep pattern and to improve perceptions of the quality of sleep.

No medication has yet been shown to provide long term remission or “cure” in people with CFS. However, there is a place for symptomatic treatment for relief of specific symptoms if

they are sufficiently distressing. As such treatments for CFS are empirical, each patient should be monitored carefully to ensure that the symptomatic benefits outweigh any side effects.

Many people with CFS report an increased susceptibility to drug side effects, and it is advisable to begin with small doses when introducing new agents[24].

Although depression is a common symptom in people with CFS, the disorder as a whole cannot be regarded simply as a “somatised” variant of a depressive illness. Overall, clinical trials of antidepressant drugs show no consistent pattern of improvement. However, judicious use of particular agents may provide symptomatic improvement in subjective energy (moclobemide), sleep disturbance (amitryptyline, nefazodone), muscle and joint pain (ami-tryptyline), and depressed mood (sertraline, paroxetine, nefazodone). A reasonable approach is to consider under- taking an “N = 1” therapeutic trial of a selected drug based on this broad pattern of effects on brain function. Given that these drug therapies are increasingly varied and complex, there is an important role for the specialist physician or psychiatrist to guide the choice of drugs and their monitoring[25].In people with the overlapping syndrome of fibromyalgia, the use of symptomatic treatments such as analgesics and NSAIDs, in combination with tricyclic agents, can be effective in reducing pain and improving sleep.

Conclusion

Chronic fatigue is one of the most Perplexing conditions in the domain of medical science.People with CFS who have a thorough knowledge of the illness tend to manage their condition better and have a more positive outlook. Whereas, people in general are not aware of this condition and it is important to know about CFS which helps to reduce the prevalence. Several studies have described how living with a chronic invisible illness results in a multiplicity of stressful consequences and considerable impact on daily life. Some people are thought to be more susceptible to the condition because of their genes, as the condition is more common in some families.More research is needed to confirm exactly what causes the condition.

Abstract

Introduction: Oral health plays an important role in general health of body. Poor oral hygiene can also lead to many systemic diseases. Dental caries is a disease with multifactorial causes. The prevalence and occurrence of dental caries in a population is influenced by many factors such as sex, age, socioeconomic status, dietary patterns and oral hygiene habits. Hence, the present study was designed to assess the prevalence of dental caries in Tiruvallur district Chennai, Tamil Nadu.

Material and Methods: The survey was carried out among school going children of age 6 years and 13 years. 399 healthy subjects including 219 boys and 129 girls from 7 different schools were examined in day light with the help of basic diagnostic instruments like mouth mirror and probe.

Result: In this study it was observed that the 9 and 10 age group of children had high percentage of caries when compared to 11 to 13 years age group of children. The mean dmft score was also high in was also high in 9 and 10 age group of children. In total dental caries was observed in 253(72.21%) study population. Restoration is the most required treatment in both the group.

Conclusion: The result of this study reveals that there are still large amounts of population that lack awareness on the effect of poor oral hygiene and oral health status and also are ignorant on the advantages of having a good health.

Key Words*: oral hygiene, dental caries, school children, prevalence, mouth mirror, probe*

Introduction

Health is a basic human right and oral health is a significant component of general health. Although oral diseases are mostly not life-threatening, they are important public health problems. [1] Dental caries is a multifactorial disease where many risk factors are involved, and it occurs because of an imbalance between the environment and external factors. Accumulation of bacteria especially cariogenic streptococcus mutants, diet, oral hygiene and time play an important role in carious lesion. However, dental caries is not a typical classical infectious disease. [2] Dental caries is specifically increasing in children. 80 to 85% children suffer from this disease and the average number of decayed, missing and filled teeth per child at the age of 12 years is about 4 in rural areas and 5 in urban areas of India with almost no dental restorative help available particularly in the rural areas. [3] Carlos and Gittelsohn (1965) were among the first to group the teeth from most susceptible to least susceptible. According to them the mandibular molars were the most susceptible and the lower incisors were least susceptible. The most frequently affected site is the occlusal surface of first and second molars. Molars are susceptible to dental caries, not only because of their location but also because of their anatomy. [4]

The prevalence of dental caries was of great interest for long and is a principal subject of many epidemiological researches being carried out worldwide. This significant but a preventable public health problem interferes with normal food intake, speech, self–esteem, and routine activities affecting overall health status of the children. [5]The prevention of dental caries has long been considered as an important labor for health profession. The world health organization (WHO) recognizes dental caries as a pandemic and reports that the prevalence of dental caries among school going children is about 60 to 90%. The risk factors for dental caries are many and they can be classified into oral and non-oral risk factors. Oral risk factors include anatomy of the tooth, composition of dental plaque, restoration and oral hygiene status. Non-oral risk factors include age, irregular tooth brushing, dietary habits and medication history. [6]School years cover a period that runs from childhood to adolescence. These are influential stages in people’s lives where lifelong substantial oral health-related behaviors, as well as beliefs and attitudes, are being developed. Children are particularly receptive during this period, and the earlier habits are established, the long-lasting, and the

impact. [7]Children who suffer from poor oral health are 12 times more likely to have more restricted activity days including missing schools than those who do not. [8]

.Studies have reported missed school hours, toothache, and several impairments of daily life activities associated with a high decayed component in both primary and permanent dentition. [9]Similar findings have been reported in Brazilian preschool children and in a school survey of American native children. [10]

Voluminous literature exists on the status of the dental caries in the Indian population. In 1997, 22.7% of Indian population was estimated to be 5 to 14 years. This being such a high proportion of the population, the prevalence of dental caries among this age group needs to be assessed. It has been observed that during 1940 the prevalence of dental caries in India was 55.5%, during 1960 it was reported to be 68%. Overall the general impression is that dental caries has increased in the prevalence severity in urban and cosmopolitan population over the last couple of decades. However there is no definite picture as yet regarding the disease status in rural and backwards areas of the country in the comparison where 80% of the population inhabits. [11]

The “Prevalence” of dental caries in an individual is obtained by calculating DMFT, which is the most common index used and for deciduous dentition dft index is used. An epidemiological study was planned as very few studies have been conducted in Chennai city. Hence, this present study was conducted as a part of the screening, to assess the prevalence among school going children of Tiruvallur district using DMFT index.

Materials and Method

The study received the approval from university review board (STP/SD 12 BDS 103).

A study of prevalence of dental caries among school going children of Tiruvallur district Chennai was undertaken by the Department of Public Health Dentistry, Saveetha Dental College and Hospitals, Chennai to evaluate prevalence of dental caries in relation to various risk factors.

The survey was conducted in 348 school children residing in Tiruvallur district, Chennai. Out 139 government schools in Tiruvallur district 7 schools were selected for the survey. The

sample consisted of 348 individuals of both gender (219 were male and 129 are females); their ages ranged from 9 to 13 years. Age of 12 years has been universally accepted as a global monitoring age for caries since all permanent teeth except third molars would have been erupted by this age. Consent for examining of the children was obtained from the respective head master. The criteria for selection of the study subjects were that the children should be permanent residents of Tiruvallur.

Depending on the physical condition of the school, the exact arrangement for conducting the examination was determined. The school children were examined under daylight with the help of plain mirror and standardized dental probes. Examination of the child was done by only one examiner to avoid interexaminer variability. Recording of data was done by a trained person who assisted throughout the study. Dental caries was evaluated and the DMFT indices were recorded respectively [12]

Result

This study aims to measure the distribution of dental caries among school going children from 9 to 13 years old in Tiruvallur district. The sample size was 348 school children of different age groups.

Table 1 shows the distribution of sample according to source of population, age and gender. The sample is divided into four groups according to age and also was divided into groups according to gender in which each group has both the gender.

Table 2 shows the prevalence of dental caries in which the highest is seen in the age group of 9 with a percentage value of 88.24%. Comparatively the other age group had a percentage value of 85.28%, 74.24%, 52.78%, 60.32%, and 72.21% respectively. Table 2 also shows the mean DMFT for the study subject which was 3.24 while the mean DMFT for different age groups (9-13 years) was 5.03, 4.76, 2.20, 2.18, 2.06, and 3.24 respectively.

Table 3 shows the prevalence of dental caries in different age groups (9-13 years old) for females. The highest percentage of dental caries prevalence was found in the age 10 and the lowest percentage of was found in the age 12.

Table 4 shows the prevalence of dental caries in different age groups (9-13 years old) for males. The highest percentage of dental caries prevalence was found in the age 9 and the lowest percentage of was found in the age 12.

Table 1: Shows the source population according to age and gender.

Age	Female	Male	Total
9 years	51	34	85
10 years	32	29	62
11 years	35	33	66
12 years	32	39	72
13 years	34	29	63

Table 2: Shows the prevalence and severity of dental caries mean DMFT in different age groups (9-13 years) old.

Age Group	Total number	Affected number	Caries prevalence %	DMFT(mean)
9	85	75	88.24	5.03
10	62	53	85.48	4.76
11	66	49	74.24	2.20
12	72	38	52.78	2.18
13	63	38	60.32	2.06
Total	348	253	72.21	3.24

Table 3: The prevalence and severity of dental caries mean dmft in different age groups (9-13 years) old females

Age	Total number	Affected number	Caries prevalence %	Dmft(mean)
9	51	42	82.35	1.53
10	32	30	93.75	2.80
11	35	27	77.14	0.50

12	32	16	50.00	0.91
13	34	22	64.70	0.52

Table 4: The prevalence and severity of dental caries mean DMFT in different age groups (9-13 years) old males

Age	Total number	Affected number	Caries prevalence %	Dmft(mean)
9	34	33	97.05	3.5
10	29	23	79.31	1.96
11	33	22	66.67	1.78
12	39	22	56.41	1.27
13	29	16	76.19	1.54

Discussion

Untreated oral diseases in children frequently lead to serious general health, significant pain, and interference with eating and loss of school time. [13] Despite incredible scientific advances and the fact that caries is preventable the disease continues to be a major health problem. The World Health Organization (WHO) has ranked dental caries, as number three among all chronic noncommunicable diseases that require worldwide attention for prevention and treatment and the fact that caries One of the factors to be considered when planning for the required growth in dental in dental facilities is the prevalence of dental diseases and their treatment need in the population. A Who Health Organization of global DMFT for 12-year-old children reported that in the 188 countries included in their database, that on global basis, 200,335,380 teeth were decayed, filled or missing among just that age group. This was based on the data available in 2004 from the WHO Oral Health Database, Country/Area Profile program (CAPP) [13]. Therefore, WHO continues to advocate that efforts to improve the overall situation are still highly indicated?[14]

The use of DMFT and dft indices has been accepted practice for assessing the prevalence and severity of caries in a population. Hence an attempt has been made in the present study which was conducted as a part of the outreach screening to assess the prevalence of dental caries among primary school going children of Chennai using dft/DMFT index.

In this study, the prevalence of dental caries has increased with age from group 9-13 years. Oral health is an integral part of our health. Lack of awareness and limited access to dental specialist has made the children in Tiruvallur district to be more prone to disease. The 9-13-year age group was chosen for the study as it is the global monitoring age for dental caries, for international comparisons and monitoring of disease trends. [15] In this study it was observed that the caries prevalence of 11 to 13 years old children was lower as compared to 9 and 10 years old age group. This shows that as age advances prevalence of dental caries decreases. This finding corresponds with the study conducted by Misra F.M (1979)[16] among 6-16 year old children in urban area of South Orissa. He observed an increase in caries level between 5 to 12 year (56% to 81%) and a decrease in caries level in 13-15year (41.4%).Similarly in the study conducted by Peterson P.E,et al (1991) [17], Retna Kumari N (1999) [18], Dash J.K (2002) [19], Saravanan S,.et al (2003) .[20]The increased prevalence of caries in boys compared to girls confirms the view that there is a marked preference for sons regardless of the socio-economic class, which manifests itself in the longer feeding of sons compared to daughters .

With the limitation of this study, further studies are required to correlate dental caries prevalence in the target population with parent's literacy level and other socio behavioral factors. Although severity of dental caries is not assessed separately in the present study; the data regarding treatment need gives a glimpse of the severity of dental caries in the study subjects.

Hence oral hygiene education and motivation are the pertaining goal to achieve proper oral hygiene health among school going children. Oral health consciousness programs should be administered by dental college and association to increase consciousness of oral and dental health. The government should provide oral health through primary health-care system and appoint dental surgeons up to primary health center level in this region.

A preventive program including pit and fissure sealant application and topical fluoride application which would be an ideal measure in the prevention of dental caries in the permanent dentition of schoolchildren would aid in protecting the permanent dentition which has to remain lifelong.

Conclusion

1. The prevalence of dental caries was high in 9-11 years of age group with highest prevalence seen in 9 years.
2. Caries prevalence showed variation in relation to sex in which male population had high prevalence of dental caries compared to female population

Abstract

Introduction: The ideal occlusion and spacing in primary dentition acts as mirror for the prevalence of malocclusion in the permanent dentition. The properly placed teeth in dental arch help in maintaining the better health of oral cavity and the supporting structures, but also influence the personality of the children. Malocclusion is a problem affecting a disproportionately large number of Indian children.The objective of the study was to assess spacing (physiological and primate spaces) in anterior region of both maxilla and mandible and to determine the molar and canine relation in Chennai school children.

Materials and Methods: 517 female school students of Velammal Matriculation Higher Secondary School, Ponneri and local schools of Chennai populations aged between 15-19yrs were examined. Prevalence of spacing was assessed by taking photographs.

Result: From the result, it has been proved that out of 517 female students who were included in this study, 51 female students had upper anterior spacing. It involved not only midline diastema but also generalised spacing wasalso considered for this study.

Conclusion: This study provides information of the prevalence of spacing and closed dentition, occlusion relation and its relation to a malocclusion. Hence, determining the malocclusion at its early age and early intervention procedure helps in preventing the problems at later stage.

Key Words: *Malocclusion; Midline Diastema; Early intervention; Preventive Orthodontics; Survey*

Introduction

Malocclusion exhibits itself mainly in three forms, one is crowding and irregularly arranged teeth, another is proclination and third is spacing. The reasons may be due todiscrepancy between arch size and tooth materials or because of habits or any other environmental aetiology. There are various studies conducted to assess prevalence of spacing in various populations.However, no such studies have been conducted in Chennai school populations to assessthe prevalence of spacing within our population. So, we have taken up such studies to examine the prevalence of spacing in school students of our population. This will help the orthodontists to get a better idea of the incidence of upper anterior spacing in our populations and in their clinical practise. study was conducted among female school students of Chennai populations. The occlusal relationship and spacing in deciduous dentition is known to have a vital bearing on the setting up of the normal occlusal relationship in permanent dentition. The ideal occlusion and spacing in primary dentition acts as mirror for the prevalence of malocclusion in the permanent dentition. The properly placed teeth in dental arch help in maintaining the better health of oral cavity and the supporting structures, but also influence the personality of the children. Malocclusion not only compromises maintaining better hygiene and also the health of investing tissue, but can also lead to behavioural (psychological) and social problems[1]. Malocclusion is a problem affecting a disproportionately large number of Indian children. The canine relation in the primarydentition is known to influence the canine relation in permanent dentition because it is thought to be a stable relation in the deciduous period. Dental aesthetics plays a major role in determining facial appearance of a person. Facial appearance of a person contributes to his self- confidence and thereby provides social recognition to a person.

The aesthetic factors are not easily evaluated and are generally determined subjectively. Identification of malocclusion by dental professional is primary factor in motivating individual to seek orthodontic care. The following patient factors appearance improvement, age, gender, environment influence and social class and orthodontist factors appreciation of treatment need, access to services, cost of treatment and treatment priority can be motivating factor to receive orthodontic treatment.The prevalence of malocclusion in India varies from 20% to 43%. Although there is plenty of literature concerning the prevalence and type of malocclusion is quoted in literature, the paucity of information is present on malocclusion in preschool children and its correlation with crowding, spacing, and closed dentition.Hence, the present study was carried out to known the impact of occlusal relationship and spacing on

malocclusion in the primary dentition. Malocclusion may cause unpleasant appearance, impaired oral function, speech problems, temporomandibular disorders, increased susceptibility to trauma and periodontal disease[2]. Identifying occlusal status in particular population provides important information on treatment needs and enables the government to draw the appropriate preventive and treatment programs. Malocclusion is regarded as an irregularity of the teeth or a malrelationship between the dental arches beyond the normal range. The aetiology of malocclusion is multifactorial, including genetic and environmental causes as well as harmful oral habits. Malocclusion represents a developmental disorder of the craniofacial complex that affects the jaws, tongue and facial muscles and is known as one of the three major oral diseases that affect human oral function, aesthetics, social interactions and health-related quality of life.

Face and dentition reflect an individual's most intimate expression such as elaborating speech and communicating; they also play a role in respiratory, masticatory, and swallowing functions. Malocclusions may cause psychosocial problems, especially concerning aesthetics, which is highly valued in current society in both personal and professional levels, lowering self-esteem and triggering a negative impact on the quality of life of children.Identifying the aetiology of malocclusions is essential for the success of any orthodontic procedure. Anthropological studies have shown changes in occlusal patterns of the population, most likely caused by softer foods in their dietary habits, non-nutritivesucking habits such as the use of pacifier and thumb sucking, respiratory problems, and early weaning. Thus, the alleged increase in malocclusion indexes between primary, mixed, and permanent dentition is considered.In addition, extensive untreated caries lesions and premature primary tooth loss contribute to compromising the occlusion of children, ranking malocclusions third in the scale of oral health problem priorities[3].

Considering the changes caused by modern living conditions and the consequent development of certain types of malocclusion, several studies prove the occurrence of malocclusion in the young population. However, data referring to primary dentition are rare in Brazil and originate from studies of distinct focus, making comparability difficult.Understanding the oral health conditions of children through epidemiological studies is fundamental for the development of adequate action proposals that may reduce the incidence of occlusion abnormality. This knowledge may also contribute to an ultimate evaluation of the impact of these actions.Regarding population, prevention is an attractive

and viable alternative for the treatment of occlusal changes, considering there is the possibility of controlling environmental variables that contribute to its occurrence.Moreover, prevention simplifies or even avoids corrective orthodontic treatments which are often inaccessible to the majority of the population. In modern countries, many sophisticated attention are given to various number of dentofacial deformities and treatment of malocclusion at an earlier stage. Treatment usually takes place at an adolescent period when the patients cooperation and motivation are at a high peak. Epidemiological investigation in the permanent dentition have become a difficult job since the significant number of populations cannot be recorded because of orthodontic treatment [4]. The aim of this study is to access spacing in both maxilla and mandible in primary dentition for treatment of malocclusion.

Materials and Methods

The study was approved by the Institutional Review Board of Saveetha Dental College and Hospital. 517 female school students of Velammal Matriculation Higher Secondary School, Ponneri and local schools of Chennai populations aged between 15-19 years were selected and screened for this study.Prevalence of spacing was assessed by taking photographs shown in [Figure 1]. The inclusion criteria were female students with upper anterior spacingand between the age group of 16-20 years. Students who had crowding and proclination without spacing were excluded from the study. Apart frommidline diastema, generalised spacing was also included in theassessment [5].

Results

From the result, it has been proved that out of 517 female students who were included in this study, 51 female students had upper anterior spacing shown in [Figure 2]. It should be noted that only midline diastema but also generalised spacing in the dentition was assessed among these students.

Discussion

This study was conducted among female school children between ages of 16-20years. Oral screening was done to 517school students between ages of 16-20years out of which 51 students has upper anterior spacing. Generalised spacing was assessed for female students apart from midline diastema.Spacing may be due to developmental causes and physiological causes. Developmental causes are spacing in deciduous teeth, ugly duckling stage and

microdontia. Physiological causes are tongue thrusting, thumb sucking, periodontal problems. These spacing can be corrected by wearing orthodontic braces, direct and indirect veneers and crowns and bridges.Spacing is the most common causes in deciduous or milk teeth.Many studies were conducted in various populations to assess prevalence of spacing among school students. According to various studies, Spacing is more common in Caucasians than Africans. Spacing of at least 2mm was found in 9.1-55.8% of the African and 7.1-59.2% of the Caucasian childrenduring different emergence stages of the dentition[6].

Early recognition of conditions predisposing young children to malocclusions is in the hands of primary care providers who for practical purposes are general practitioners and the paediatric dentist. It is important that conditions that predispose to develop a malocclusion of the permanent dentition be detected early in the primary dentition so the early interceptive procedure can be applied to prevent its further consequences. The presence of spacing or crowding and occlusion in the primary dentition and its relation to the developmentof malocclusion has been the long subject of discussion. There are many studies done regarding correlation of spacing or crowding with the malocclusion in pre-school children but still the knowledge of it is scares. The development of malocclusion starts from the primary dentition, so it is very important to know the occlusion in the primary dentition, as well as the changes of occlusal pattern, during the period of deciduous dentition. According to Bishara et al., marked arch width (inter canine and intermolar width) expansion occurs significantly between 3 and 5 years of age in both maxilla and mandible [7]. Therefore, the school children included in current study was limited to 20 years. Joshi and Makhija conducted study on 3-6 years' school children in Gujarat and concluded that non-spaceddentition was less common in school children when compared to spaced dentition.

A significant difference was noticed in which amount of spacing was found to be greater in males.Almost similar results were obtained in various studies [8]. Im et al., concluded that maxilla showed more spacing when compared to mandible irrespective of sex. ElNofely et al., assumed that spacing can be either due to small mesiodistal or wide inter canine width. Leighton's hypothesis suggests that for the proper alignment of permanent teeth in mandibular arch, the amount of spacing in primary dentition should be of 6 mm or more. The study concluded that flush terminal molar relation recorded highest (74%) followed by mesial step (22%) and then distal step (4%) in all the age groups but with increase mesial step molar relation increased to 33% at the age of 6 years[9]. Similar results were obtained by Baume

showed that flush terminal plane (76%) is more commonly seen followed by mesial step (14%) and then distal step molar relation (10%). The study results shown highest bilateral flush terminal plane molar relation in children from Hyderabad (72.5%) and Chennai (74%) as concluded by Sriram et al., On contradictory, several other studies have shown that mesial step relation recorded highest followed by flush terminal plane and distal step. Bahadure et al., shown highest the rarest occurrence of mesial step molar relation (57.3%) followed by flush terminal plane (31.1%) and then the distal step molar relation (11.7%) [10].

The changes in the occlusion can be attributed to a combination of mesial migration of the lower arch and a mesial shift of the mandible, which is probably caused by growth. Considering canine relation, the most common relation found was Class I (90%) canine relation followed by Class II (6.4%) and Class III (3.6%) canine relation at the age of 2-3 years. At the age interval of 5-6 years Class I relation was found to be 82%, Class II relation was 9.8%, and Class III was 7.6%. Baidaset al., concluded that among the canine relation, Class I (90.1%) showed peak value succeeded by Class III(7.4%), and Class II (2.5%) relationship, which are similar to the present study. On the contradictory, Bahadure et al. concluded that among the canine relation, Class I (47.20%) showed highest value followed by Class II (42.83%) and Class III (9.97%) [11]. There were studies done on how spacing and occlusion is related to malocclusion and what were the possible reasons for the malocclusion. Howe concluded that malocclusions were discrepancy in arch length and tooth size.

The major reasons for the malocclusion may be due to the modern diet, which results in decreased inter-proximal wear and jaw growth[12]. According to Profit, oral habits such as mouth breathing, thumb sucking might also be responsible for crowding in the arch.Prevention and early treatment in orthodontics is still the subject of continuous debate and controversy regarding cost effectiveness analysis and functional and psychosocial benefit[13]. In recent articles, Gianelly et al., favoured treatment in the late mixed dentition for 90 percent of the children while Viazis et al., concluded that early orthodontic/orthopaedic treatment would be profitable and desirable in younger patients. In this study, it was observed that malocclusion is actually commonplace in the temporary dentition[14].

Obvious similarities could be seen and also in with other investigations of occlusal traits in the primary dentition. The available documentation also suggests that development of the

occlusion is a continuum for many aspects: most of the major occlusal trends characterizing the adult dentition were detectable at early stages. Lack of space was common, as well as lateral crossbites, excessive overjet or Class II relationships; the striking difference from data concerning the permanent dentition was the high prevalence of open bites which are expected to decrease with maturation. In the absence of longitudinal documentation and with due reservation to the possible biases inherent to cross-comparison of epidemiological data on malocclusion, we are inclined to conclude that, provided the patient'scooperation is established early, consideration may be given to treatment of the malocclusion. This concern should be focused mainly on lateral crossbites and sagittal relationship.

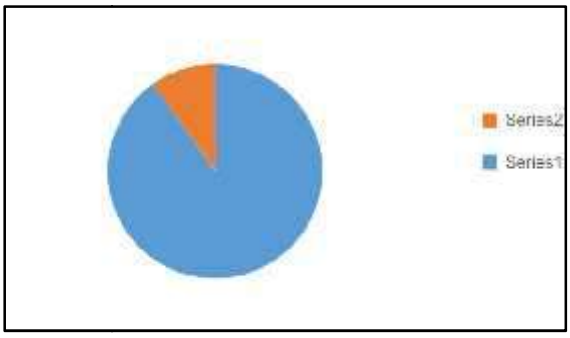
The most common trait of malocclusion was revealed to be a deep overbite (33.66%), which is consistent with a previous study. However, deep bite in primary dentition may be temporary, and spontaneous correction may occur due to vertical growth of the mandibular ramus and the full eruption of permanent molars, as a longitudinal study supported [15]. Scholars have recommended that an increased overbite in primary dentition is rarely treated unless the lower incisors impinge the maxillary palatal mucosa, leading to pain or other clinical symptoms. Physiological spaces, including the developmental spaces and the primate space, were the second most common characteristic in primary dentition, with a prevalence of 27%. Spacing indicates proper alignment of the permanent dentition; thus, early effective treatment is not necessary in such cases. Cross bite (25.29%), mainly associated with genetically inherited characteristics and environmental factors, was observed at a higher prevalence than that reported in India [16]. Self-correction was noted for anterior crossbite, whereas posterior crossbite was transferred from the deciduous to the permanent dentition. Likewise, crossbite warrants increased early check-ups and treatment to decrease the long-term effects on growth and development. Relative to the reported prevalence of increased overjet in the primary dentition in different countries, which ranges from 3% to 16%, the prevalence rate in the present study was moderate, at 10.16%. Because increased overjet was alleviated during the transition from primary to permanent dentition, it was not a precise indicator of a similar increase in the permanent dentition. In addition, a standard of 3 mm is acceptable to clinicians. The prevalence of crowding (8.03%) was much lower than that reported in Colombia (52.1%)[17]. This difference might be the result of a sampling error secondary to the small sample size in the former study.

There are clear indications that crowding in deciduous dentition, mostly due to the modern diet, contributes to the disproportion between the jaw and tooth size in the permanent stage; thus, early interceptive treatment is necessary to enhance the favourable growth and development of the jaw and teeth. Moreover, the discrimination between temporary malocclusion and pathological malocclusion is crucial in this period.Some study revealed a dramatic increasing trend in the prevalence of malocclusion over time among children in mainland China, which suggests the need for the early recognition and treatment of deciduous-dentition malocclusions in further diagnostic and treatment procedures. There are several potential reasons for this observation[18]. First, the rapid development of China's economy has changed lifestyles and diet structures among its inhabitants, and the overconsumption of refined and high-sugar foods has increased the risk of malocclusion. Second, a lack of proper oral hygiene knowledge, attitudes or behaviours among parents has likely contributed to the increasing prevalence of malocclusion among children. For example, there is a general misunderstanding that malocclusion in primary dentition is temporary and should resolve with the eruption of permanent teeth. Additionally, the government's investment in oral health services and resources, as well as health education programmes, is insufficient, especially in rural areas[19].

The present study demonstrated that the majority of children in mainland China had a flush terminal plane (47.10%), followed by a mesial step relationship (43.24%) and a distal step relationship (5.04%). In India, a survey of 1,000 pre-schoolers revealed similar results; the molar relationship prevalence was the flush terminal plane (66.0%), mesial step (12.8%), distal step (2.4%) and bilateral symmetry (18.8%). There was a consensus that the distal surfaces on the second deciduous molars, i.e., the primary molar relationship in the deciduous dentition, predicted the identification of the permanent molar relationship[20]. A previous surveyrevealed that most cases of flush and mesial terminal plane developed into Angle Class I in the permanent dentition due to a combination of forward movement of the mandible and mesial migration of the mandibular arcus. Additionally, a study by Ravn et al., demonstrated that a distal step molar relationship could develop into an Angle Class II molar relationship in permanent dentition. Therefore, additional longitudinal studies are necessary to identify the changes in the molar relationship from primary dentition to permanent dentition[21].

Figure 1: Assessment of midline spacing and generalised spacing

Figure 2: Prevalence of Spacing among Chennai School Children



Series1- 517 female students
Series 2- 51 female students

Conclusion

This study provides information of the prevalence of spacing and closed dentition, occlusion relation and its relation to a malocclusion. In the study, spaced dentition was more frequent the non-spaced dentition. In this study female populations had upper anterior spacing in their early stage which can be corrected by further orthodontic treatment. Hence, determining the malocclusion at its early age and early intervention procedure helps in preventing the problems at later stage.

Abstract

Introduction: The most important causes of this disorder can be awkward postures, repetitive and rapid movements, excessive force, psychological factors, genetic and generally inappropriate body condition. Damage or injury can be defined as a disorder of the musculoskeletal system (muscles, ligaments, tendons, joints, nerves, blood vessels and soft tissues). The symptoms of MSDs increase with the number of years of practice. The prevention and reduction of MSDs among dentists should include their knowledge in dental ergonomics and awareness regarding the importance of work-related risk factors. This study aimed to identify risk factors for musculoskeletal disorders among dentists and identify its effective risk factors, in order to reduce musculoskeletal problems and is designed to improve the work environment.

Materials and Methods: The target population of this investigation was the students of dental school.A sample of 300 questionnaires were distributed.To determine the prevalence of musculoskeletal disorders, questionnaire was prepared.The Questionnaire assessed the musculoskeletal disorders, pain in different organs of the body.Finally the results are evaluated in percentage

Results: Out of 300 questionnaires distributed, the female prevalence was higher.86% of the people don’t do physical exercise daily.71% of the dental students take rest after each patient, 15% take rest once an hour and 13% of the students never take rest at all.95% of the dental students involve frequent bending of elbows and joints.91% of them feel some kind of musculoskeletal discomfort in the body and other 9% are free from it. Most discomfort is felt

in the neck region that is 41% and 23% in one or both elbows,15% in one or both shoulders and 20% in back/spine.66% of the students feel the pain most of the time and 22% always and 11% at times.50% of the students follow periodic stretching and breaks as the pain relief strategy.36% follow postural awareness strategy and 13% follow strengthening exercises.

Conclusion: Therefore dentists should implement right ergonomic designs in their dental clinics along with doing regular exercise and relaxation techniques, which help them to combat stress, thus improving the quality of life and resulting in consistent long-lasting work efficiency of the dentists.

Key Words: *musculoskeletal,dentists,pain, long lasting work,occupational.*

Introduction

Today, work related musculoskeletal disorders (WMSDs) are one of the most common occupational diseases and causes of disability in developing countries.[1]The most important causes of this disorder can be awkward postures, repetitive and rapid movements, excessive force, psychological factors, and genetic and generally inappropriate body condition. Damage or injury can be defined as a disorder of the musculoskeletal system (muscles, ligaments, tendons, joints, nerves, blood vessels and soft tissues)[2].Studies have shown that the best strategy to prevent WMSDs is to reduce exposure to risk factors such as repetitive movements, excessive force, awkward postures, vibration and static work.

This study aimed to identify risk factors for musculoskeletal disorders among dentists and identify its effective risk factors, in order to reduce musculoskeletal problems and is designed to improve the work environment.Musculoskeletal disorders have become increasingly common worldwide during the past decades. It is a common cause of work-related disability among workers with substantial financial consequences due to workers' compensation and medical expenses. Various work-related factors have been established as predisposing the disorders. In dentists, overstrained and awkward back postures for back pain, repetitiveness for neck and shoulder disorders, and psychosocial stressors for back, neck and shoulder complaints. A slight hand neuropathy has also been reported caused by exposure to high frequency vibration tools.In most studies only a few of these risk factors have been taken into account simultaneously.

This makes it difficult to appreciate the impact of specific risk factors since most studies did not control appropriately for concurrent risk factors. In Greece, very few studies have been undertaken in occupational groups with respect to the simultaneous occurrence of different musculoskeletal complaints and their interrelationships .The first aim of this study was to investigate associations between personal characteristics, physical load, psychosocial factors and general health status with complaints of back, neck, shoulder and hand/wrist. The second aim was to analyses interrelations between these musculoskeletal complaints and its effect on associations between work-related risk factors and musculoskeletal complaints.Dental surgeons often cannot avoid prolonged static postures. Even in optimal seated postures, more than one-half of the muscles of the body are contracted statically and there is little movement of the vertebral joints. This may result in damaging physiological changes that can lead to back, neck, or shoulder pain or MSDs.

If regularly occurring pain or discomfort is ignored, the cumulative physiological damage can lead to an injury (macro change) or a career-ending disability.Basic operating posture is considered an important occupational health issue for dental surgeons. It is generally agreed that the physical posture of the operator should be such that all the muscles are in a relaxed, well-balanced, and neutral position. Postures outside of this neutral position are likely to cause musculoskeletal discomfort. A thorough understanding of the underlying physiological mechanism leading to these problems is necessary to develop and implement a comprehensive approach to minimize the risk of work-related injury.[3,4]In dentistry, bad working habits and repetitive tasks such as scaling, root planing, and uncomfortable physical postures contribute greatly to MSDs, stress, and loss of productivity. The key objective for clinicians is to find a position that allows them to achieve optimum access, visibility, comfort, and control at all times.

Materials and Methods

The target population of this investigation was the students of dental school.A sample of 300 questionnaires were distributed.To determine the prevalence of musculoskeletal disorders, questionnaire was prepared.The Questionnaire assessed the musculoskeletal disorders, pain in different organs of the body.Finally the results are evaluated in percentage.These questions addressed items such as tiredness after work, fatigue, lack of concentration, putting interest in

other people, the ability to recover from work, and the influence on work performance.For both general health endpoints subjects with a score above the median value were considered to have a high need for recovery or a moderate/bad general health.Musculoskeletal complaints were measured using the standardized Nordic questionnaire . Four endpoints for each body site were defined: (i) musculoskeletal complaint of back, neck, shoulder or hand/wrist was defined as pain in the past 12 months, which had continued for at least a few hours during the past 12 months, (ii) chronic musculoskeletal pain in the past 12 months, referred to a complaint that was present almost every day in the preceding 12 months with a minimal presence for at least 1 month, (iii) musculoskeletal complaint which led to a period of sickness absence in the past 12 months, and (iv) musculoskeletal complaint which led to medical care seeking in the past 12 months.

Results

Table 1: Mostly followed working position by the practitioners

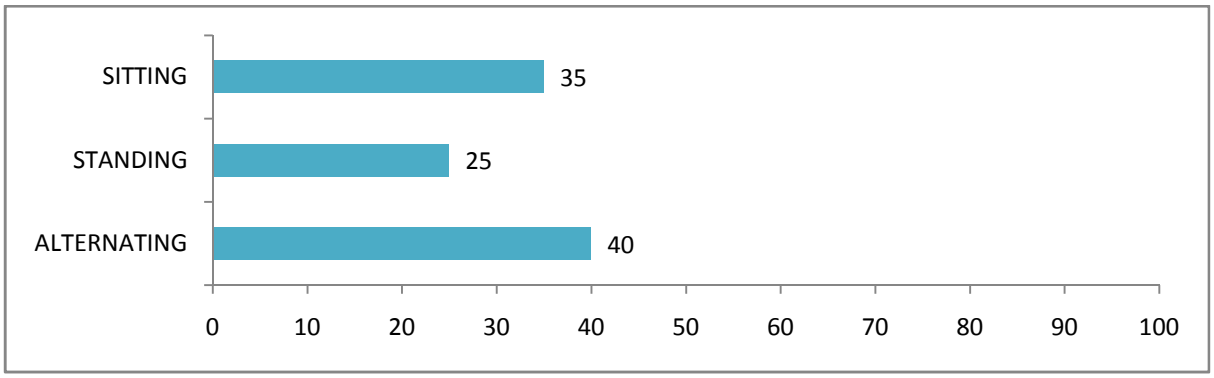

Table 2: The part of the body in which most discomfort is felt

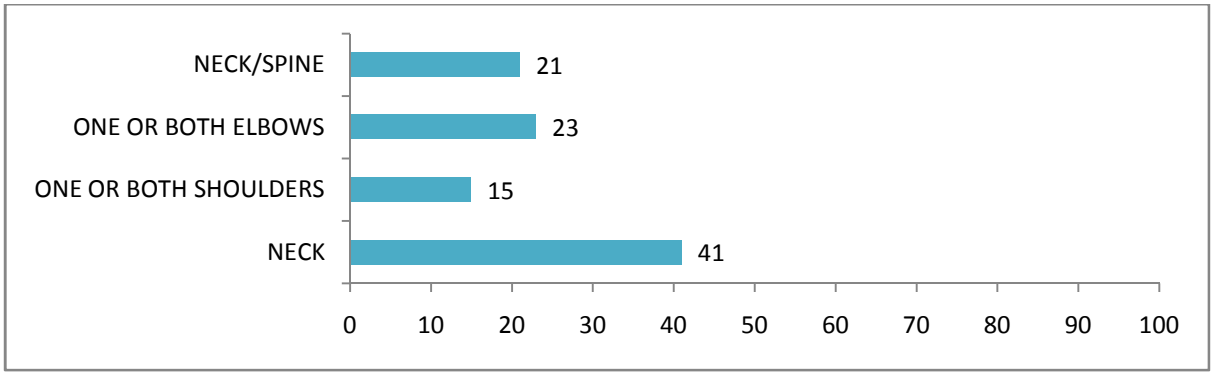

Table-3 Frequency of pain

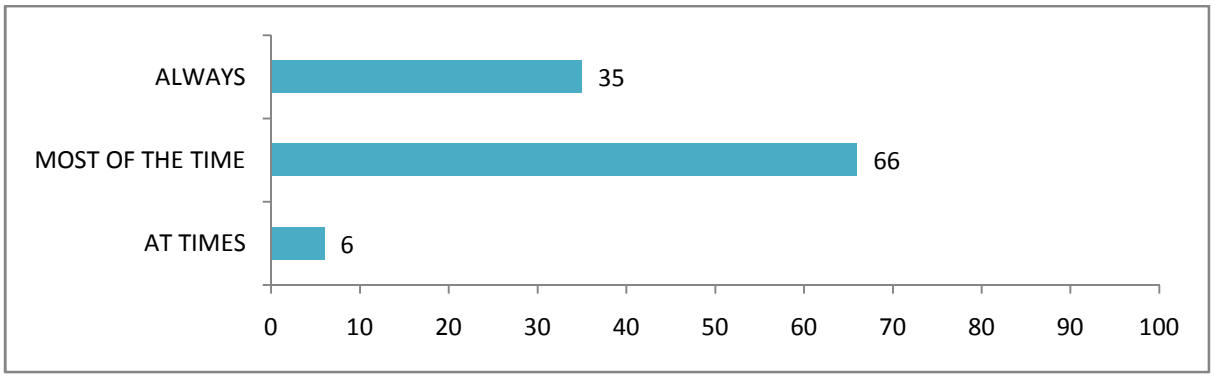

Out of 300 questionnaires distributed, the female prevalence was higher.86% of the people don't do physical exercise daily.71% of the dental students take rest after each patient, 15% take rest once an hour and 13% of the students never take rest at all.95% of the dental students involve frequent bending of elbows and joints.91% of them feel some kind of musculoskeletal discomfort in the body and other 9% are free from it. Most discomfort is felt in the neck region that is 41% and 23% in one or both elbows,15% in one or both shoulders and 20% in back/spine.66% of the students feel the pain most of the time and 22% always and 11% at times.50% of the students follow periodic stretching and breaks as the pain relief strategy.36% follow postural awareness strategy and 13% follow strengthening exercises.

Discussion

The number of years of practice plays an important role in the occurrence of MSDs, although both younger and older dentists report the same symptoms, as confirmed in other studies also.Young general dental practitioners work very intensively in the first years of practice, often over 8 hours a day, which causes an early occurrence of MSDs, even within 3 years. Possibly due to experiencing pain and muscle stiffness they start to keep fit and work less intensively, this is why they do not experience the pain in the next few years.[6,7,8] Findings suggest that by raising awareness of these problems among students, the risk of MSDs can be reduced. It has been recommend that as a preventive measure; students should be taught, from the beginning of their undergraduate studies, about optimal working postures and good work habits. In this cross-sectional study, we found high prevalences for back pain, neck,

shoulder and hand/wrist complaints. Musculoskeletal problem was too high and a proportion of the subjects reported chronic complaints and seeking absenteeism.

Self-reported physical risk factors were important for the occurrence of musculoskeletal complaints whereas age, gender and perceived moderate/bad general health were strongly associated with chronicity of complaints and medical care seeking. Musculoskeletal sickness absence was related to perceived exertion and family situation.Inthis survey self-administered questionnaires were used to collect information about physical and psychosocial load and perceived health.Like most studies significant relations were found between self-reported physical risk factors and the occurrence of musculoskeletal disorders in various body sites. Since our study did control appropriately for concurrent risk factors, it was possible to disentangle the most important risk factors among the strongly interrelated factors of physical load, psychosocial load, and general health. The results demonstrate the importance to separate risk factors for the occurrence of musculoskeletal complaints from factors that determine their aggravation and consequences for disability. The occurrence of musculoskeletal complaints among dentists was associated with which seems to be especially important for hand/wrist complaints. Work-related psychosocial factors played an inconsistent role in the development of chronicity of complaints. The strongest impacts in all outcomes under study i.e. occurrence, chronicity, comorbidity and medical care seeking was held by perceived general health.[5,6,7]

Perceived health partly incorporate psychosocial factors as low control and working without breaks. High job demands increase the need for recovery, which is related to worst perceived health. This might reflect an influence particularly on more severe disease or an effect on people's ability to cope when symptoms occurred. The clear differences between work-related risk factors and general health with respect to the observed associations with different endpoints of musculoskeletal health calls for further exploration of these associations in various occupational groups and national settings.[8,9,10]Dental surgeons are normally included within the group of professionals at risk of suffering from MSDs due to prolonged awkward or forced postures at work and failure to adopt preventive measures.The present study found that most of the dental surgeons had some kind of musculoskeletal pain and stiffness while performing their professional work in the last 6 months.

The mechanism of musculoskeletal pain production has been studied extensively. The onset of modern dentistry, as evidenced by four-handed dentistry, has made the major part of the dentist tasks purely sedentary in nature. This has resulted in dramatic rise in musculoskeletal symptoms.Karwaski*et al*. reported that the symptoms are a product of many risk factors including prolonged static postures, repetitive movements, and poor positioning. Ratzen, on the other hand, linked musculoskeletal pain occurrence in the dentists to the frequent assumption of static postures, which usually requires more than 50% of the body's muscles to contract to hold the body motion less, while resisting gravity.[11,12] The static forces resulting from these postures have been shown to be much more tasking than dynamic forces. Repeated prolonged static postures are thought to initiate a series of events that could account for pain, injuries, or career-ending problems seen in MSDs.Lalumandir*et al*. reported that all dental specialties show a high occurrence of MSDs, but with variations in frequency and locations. In this study, we found that frequency of pain varies with the number of patients treated per day in the area of hip/thigh and with the height of the dentists in case of hip/thigh and knee joints.[13,14,15]

Conclusion

The prevalence of musculoskeletal disorders in young dentists is 41%. Neck is the most common affected region[16,17]. Stress and lack of exercise are the main associated factors for musculoskeletal problems in dentists. In conclusion, it was recognized that limited ergonomics in the work environment of the dentists' results in MSDs, and its prevalence is very high.The symptoms of MSDs increase with the number of years of practice. The prevention and reduction of MSDs among dentists should include their knowledge in dental ergonomics and awareness regarding the importance of work-related risk factors.[18,19,20]The musculoskeletal disorder is one of the disease that most related to the dentist work. Therefore dentists should implement right ergonomic designs in their dental clinics along with doing regular exercise and relaxation techniques, which help them to combat stress, thus improving the quality of life and resulting in consistent long-lasting work efficiency of the dentists.[21,22]

APPENDIX-1:

The Questionnaire Is As Follows

PREVALENCE OF MUSCULOSKELETAL DISORDERS AMONG DENTAL STUDENTS - A QUESTIONNAIRE SURVEY

AGE- YEARS OF CLINICAL PRACTICE- NO OF CASES PER DAY-

1. Gender

a) Male b) Female

2. Will you do physical exercise daily?

a) Yes b) No

3. How long do you take rest while working?

a) Never b) Once in an hour c) Once for every patient

4. Which is your mostly followed working position?

a) Sitting b) Standing c) alternating

5. Does your working position involve frequent bending of elbows and joints?

a) Yes b) No

6. Do you feel any musculoskeletal discomfort in your body?

a) Yes b) No

7. If so, in which part of the body do you feel the most discomfort?

a) Neck b) One or both shoulders c) One or both elbows d) Back/Spine

8. Musculoskeletal symptoms are most felt in which part of the body?

a) Upper limb b) Lower limb c) Both

9. How long is the duration of pain?

a) At times b) Most of the time c) Always

10. Do you follow any pain relief measures?

a) Postural awareness strategy b) Periodic breaks and stretching c) Strengthening exercises

Questionnaire Survey about Knowledge of Incremental Techniques in Composite Placement among Dentists in South India

N.S.Harini[1], Jayalakshmi Somasundaram[2], Sankari M[3]

Graduate Student[1], Senior Lecturer[2], Department of Conservative Dentistry and Endodontics[2], Professor[3], Department of Periodontics.

Abstract

Introduction: Dental composite resins are types of synthetic resins which are used in dentistry as restorative material or adhesives. Synthetic resins evolved as restorative materials since they were insoluble, aesthetic, insensitive to dehydration. Polymerisation shrinkage is one of the major disadvantages in composites due to "c" factor. To reduce this configuration factor incremental techniques have been used. Several incremental techniquesbeing followed by dentists. Incremental techniques is one of the most comfortable and qualitative technique which reduces "c" factor in composites. This is a questionnaire survey which assess the most practiced incremental technique by various dentists.

Material and Method: A questionnaire survey about the most popularly used Incremental techniques being used in composite placement by several dentists have been analysed.

Results:70% of dentists are practicing incremental techniques in composite placement. The rest 30% of dentists are practicing bulk fill techniques. Of the dentists practicing incremental techniques 71.43% are following oblique layering technique, 14.29% are following three site novel matrix and the rest 14.29% are following successive cusp build up technique

Conclusion: Of the three incremental techniques, oblique layering technique has many advantages such as allows easier Class II build-up, with proper proximal contact and proximal smooth surfaces. Another advantage is that there is adequate light exposure for polymerization.

Key Words:*Knowledge, incremental techniques, composite placement, dentists, oblique layering.*

Introduction

We are now living in a era of aesthetic dentistry where tooth coloured restorations matching the shade of natural teeth are the most in demand. Since necessity is the mother of invention, evolution of composite resins has seen a cutting edge over other dental restorative materials.

Composite resins are widely used in dentistry to restore teeth with structural loss due to their aesthetics and physical properties. However, these restoratives have polymerization shrinkage as an inherent problem that may cause residual stresses in the tooth, even when not in function[1,2]. Clinical signs that have been associated with polymerization shrinkage stress include inadequate adaptation at tooth/restoration interface, micro-cracking, postoperative sensitivity, microleakage, and secondary caries[3,4].These issues are often responsible for replacement of composite restorations in posterior teeth[5,6]. Changes in material formulations and filling techniques, aimed at reducing volumetric contraction and shrinkage stress, have been the primary approaches for reducing the development of residual stresses[7,8].Composite restorations also hold other advantages such as they match the shade of the natural teeth, are Mercury- free, thermally non - conductive and bond to the tooth structures with the use of adhesive agents. Placing successful posterior composites is exacting, tedious and time consuming. The process includes achieving the necessary isolation, selecting and placing an appropriate matrix, precise execution of the adhesive steps, the placement of a flowable resin or resin ionomer liner and finally, the incremental placement, adaptation, and light curing of at least two or more layers of composite. Add to this sculpting, adjusting the occlusion and finishing and polishing and have a procedure which just takes too much time. This in turn can produce a profitability problem for dentists who have contracted with insurance companies. Given today's overhead per hour, dentist's need material and technology advancements so that posterior composites can be placed faster, easier, and profitably without taking compromising shortcuts[9,10].In recent years, materials have been introduced in an attempt to reduce some of the time and effort needed for layering and adaptation when placing posterior composites.

However the life of a resin composite restoration is dependent on several factors, including the cavity-composite interface sealing. From this view point factors related to gap formation mechanism are crucial in improving the clinical longevity of resin composite restorations. Although composite resins possess numerous advantages, one predominant disadvantage is polymerization shrinkage. This shrinkage can lead to failure of the restoration because of the "C" factor or Configuration factor. This "C" factor can be minimized by incremental technique. A lot of different incremental techniques have been proposed so far by various authors. Composite resins with high elastic modulus produce more rigid restorations, which increase

the effect of polymerization contraction on residual shrinkage stresses [11]. Filling techniques also influence stress distributions. The potential of incremental composite placement technique to reduce the shrinkage deformation and stress at the adhesive interface is controversial [12-14]. An incremental technique could increase shrinkage stresses due to incremental cuspal deformation by each polymerized increment. The incremental cuspal deformation also leads to a reduction in the volume of the cavity, reducing the amount of composite that is placed in subsequent increments [14].

Material and Method

A questionnaire survey containing 10 questions was taken to assess the knowledge about incremental techniques in composite placement among various dentists in south India for which the sample size was 400

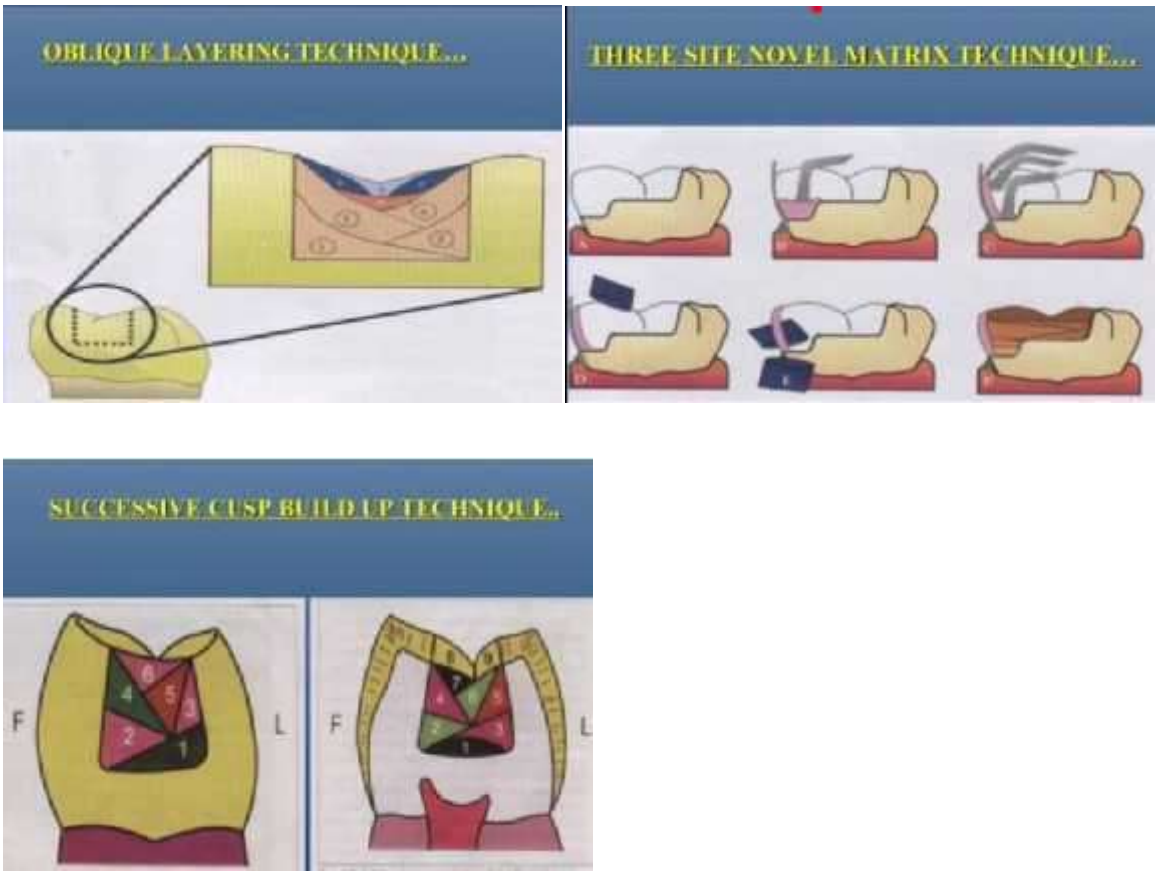

Figure 1: Diagram Showing Various Incremental Techniques in Composite Placement

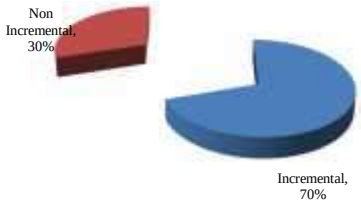
1. Years of Experience in dentistry?	10 years/15 years/> 15 years
2. Have you been trained in composite placement?	Yes/No
3. Do you prefer incremental technique or bulk placement technique?	Incremental/Bulk
4. Which incremental technique do you prefer in composite placement?	
Three site novels matrix/Oblique layering technique/Successive cusp build up	
5. Factors influencing to follow that technique?	
6. Disadvantages of that technique?	Yes/No
7. Overall grade for that technique?	Poor/Good/Excellent
8. Post treatment problems?	Present/Absent
9. Do you use any flowable composites under packable composite?	Yes/No
10. Is the patient satisfied with your composite placement?	Poor/Good/Excellent

Figure 2: Questionnaire

Results

This study is a survey which is aimed to find out the most commonest incremental techniques practiced among dentists. The results of the survey are given below:

70% of dentists are practicing incremental technique in composite placement. The rest 30% of dentists are practicing bulk fill technique. Among the dentists practicing incremental techniques, 71.43% are practicing oblique layering technique, 14.29% are practicing three site novel matrix technique,, and the rest 14.29% are practicing for successive cusp build up technique.



INCREMENTAL TECHNIQUE

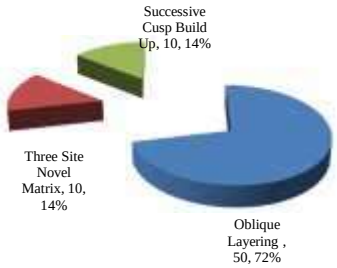


Figure 3: Pie chart showing various techniques used in composite placement among dentists

Discussion

Resin composite restorations have gained popularity because they match the shade of the natural teeth, are mercury-free and thermally non-conductive, and they bond to the tooth structure with the use of adhesive agents.

Direct dental composites can be used for:

- Filling cavity preparations
- Filling gaps which are diastemas between teeth using a shell-like veneer or
- Minor reshaping of teeth
- Partial crowns on single teeth. Although composites are now the material of choice for most restoration, their polymerisation shrinkage remains a problem.

Configuration Factor

Resin composite restorations have gained popularity because they match the shade of the natural teeth, are mercury-free and thermally non-conductive,[15] and they bond to the tooth structure with the use of adhesive agents[16]. Although composites are now the material of choice for most restoration, their polymerization shrinkage remains a problem.

Modern resin composites undergo volumetric contractions of between 2.6 and 7.1%,[17]resulting in shrinkage stress generation at the composite-tooth interface[18]. These stresses may cause the composite to pull away from the cavity margins, resulting in adhesive failure and marginal gap formation [19]. Oral fluids containing bacteria may fill these gaps, causing micro leakage and secondary caries. Other adverse consequences of shrinkage stresses include coronal deformation resulting in postoperative sensitivity, propagation of existing enamel micro cracks, and micro cracks of composite resin due to cohesive failure [20].

In 1987, Feilzer *et al*. postulated that the geometric configuration plays an important role in the adaptation of resin composite restoration [21]. The cavity configuration (C-factor) is defined as the ratio of bonded to unbonded surfaces. A high ratio denotes high polymerization stresses, which are accompanied by increased shrinkage stresses. Among many of the factors contributing to the shrinkage stresses, C-factor is an important one.

Several techniques have been suggested to improve marginal adaptation of high C-factor preparation, including adhesive systems that potentially resist composite shrinkage[22, 23] placement techniques for resin composites,[24,25]protocols for polymerisation and different cavity preparations[26].

Internal stress can be reduced in a restoration subject to potentially reduce high disruptive contraction forces by using:

- "soft-start" polymerization instead of high-intensity light curing
- incremental layering to reduce the effects of polymerization shrinkage; and
- a stress-breaking liner, such as filled adhesive, flowable composite, or resin modified glass ionomers.
- The application of non or low shrinking restorative materials[25,26].

The Incremental Layering Technique

Incremental layering has been advocated for use in large composite restorations to avoid the limitation of depth of cure, to reduce the effects of polymerization shrinkage, and to enhance the aesthetic results from the multilayering of colour. Incremental layering with successive layers of dentin and enamel composite creates high diffusion layers that allow optimal light transmission within the restoration, providing a more realistic depth of color as well as natural surface and optical characteristics. The polychromatic effect is achieved by stratifying variations in shades and opacities of the restorative composite.

Polymerization stresses generated by polymerization shrinkage may compromise the bond integrity, leading to concerns such as micro leakage, postoperative sensitivity, and ultimately secondary caries.If the composite-tooth bond remains intact, stresses transferred to tooth structure may result in cuspal flexure, enamel fracture, or fractured cusps.

Due to the variations in natural teeth, the combinations of different composite shades must be applied in relationship to the anatomy of the tooth, and are specifically adapted to different clinical situations.

In order to minimize micro leakage, different incremental insertion techniques have been suggested as a way to improve composite curing in-depth and minimize the effect of confinement on contraction stress development. Instead of using a bulk technique, layering techniques may have some advantages, that is, the use of a small volume of material, a lower cavity configuration factor and minimal contact with the opposing cavity walls during polymerization[10, 12]

Three Site Novel Matrix Techniques

The technique indicates the use of a metallic matrix band and wood wedges to provide an interproximal contour and contact with the adjacent tooth as well as to provide an adequate cervical adaptation. The first increment of the packable composite resin is applied on the gingival wall of the proximal box, packed cervically near the axial wall and, automatically, the resin climbs up in contact with the inner surface of the matrix band. This increment is sculpted and light-cured and the metallic matrix band is removed. Thus, the Class II cavities are transformed into Class I, with free access for light-curing. Small incremental layers of composite fill the remaining cavities. This technique is faster than conventional techniques and permits appropriate embrasure, better contour, and contact points[13-15].

Oblique Layering Technique

The presence of a high c-factor is a risk for debonding within the resin–dentin interface. For deep Class I cavities, horizontal layering is the most promising way to get a good bond to the cavity floor

Using four horizontal increments, achieved higher bond strengths and to reduce the possibility of cuspal flexure, a composite hybrid with a low volumetric polymerization shrinkage should be used. Opposing enamel walls should not be contacted by the same increment;this will minimize the wall-to-wall shrinkage and thus reduce intercuspal stress. The application of the composite in oblique layers results in fewer contraction gaps at the margins. It is important to continue to condense and shape the composite resin to correspond to cusp development and replacement of dentin[26].

Successive Cusp Build Up Technique

Successive cusp build-up is an improved placement technique for posterior direct resin restorations. By placing successive layers of apicoocclusal wedges of composite, the C-factor for each layer is extremely reduced. This technique gives up a glossy finish and is aesthetically much better than any other restoration.

In this study, 70% of the dentists are practicing incremental technique in composite placement. The rest 30% of dentists are practicing bulk fill technique. Among the dentists practicing incremental techniques, 71.43% are practicing oblique layering technique,14.29% are practicing three site novel matrix technique,, and the rest 14.29% are practicing successive cusp build up technique.[27]

Thus oblique layering technique is the most practiced incremental technique by various dentists in south India.

Reasons to prefer oblique layering technique:

Reduce "c"factor, High strength, Withstand maximum masticatory stress, Rapid and aesthetic, Allows easier Class II build-up, with proper proximal contact and proximal smooth surfaces. Another advantage is that there is adequate light exposure for polymerization[27].

Conclusion

Composite restorations have revolutionized restorative dentistry due to their conservative nature, adhesive bonding and patient appeal. The adhesive bonding, ability makes it unnecessary to remove tooth structure for retention, prevention, and convenience. Successful restorations can be done with less precise preparations [28].There is mercury present in the silver filling material, called amalgam, in the past century there has been no evidence showing that silver fillings are harmful to patients. But nowadays dentists doesn't use amalgam filling because of its various disadvantages like it can corrode over time, amalgam filling does not bond (hold together) with your tooth etc. Composite fillings are primarily a resin which has been" filled" with other inorganic materials. This compound makes a composite filling more resistant to wear, colour adjustable, and easier to polish [29].Composite resin, serves as esthetic alternative to amalgam and cast restorations [30].The marginal integrity of composite restoration refers to its marginal fit and marginal adaptation thereby increasing the longitivity of the restorative material [31].Resin composites have been the pinnacle of direct esthetic restorations ever since its discovery [32]. It is justifiable to speak of future dental practice because it takes many years for nascent technology emerging from scientific research laboratories to be developed and made commercially available for dentists' use. Therefore, some of the current research successes represent future improvements in patient care. The durability, reparability, and quality of the surface texture of composites are matters that are receiving considerable research. Anything which improves the strength and durability of this interaction could lead to restorations that are stronger and more durable. Future improvements in the level of oral hygiene, the use of fluorides, antiseptics, sealants, and protective coatings to prevent decay, together with improvements in composites to repair traumatically damaged or malformed teeth, can lead to better general health because of better oral health.

Abstract

Introduction: The foundation for healthy permanent teeth in children and teenagers is laid during the first years of life. Poor oral hygiene and inadequate tooth brushing habits during the first two years of life can cause dental problems in future according to several studies. This study aims at evaluating the awareness of the need for dental treatment among parents of school going children visiting Saveetha dental college and hospitals.

Materials and Methods: Poor dental health in preschool-aged children can lead to pain [1,2], may affect their growth and quality of life [3-6]and may have a chance of developing future dental problems. Growing children need proper guidance for healthy growth, upkeep and hygiene of their teeth and parents need to be educated on the importance of dental treatment. Parents should receive counselling on appropriate oral hygiene procedures, fluoride supplementation,oral habits and also need for clinical intervention for their children because knowledge regarding risk amongst parents may be variable. A convenient sample of 150 participants who are parents of school going children visited Saveetha Dental College and hospitals for treatment were included.

Results: This study shows that the importance of parental knowledge on their child's dental health. Parents are not fully familiar with oral hygiene techniques and dental treatment methods but more awareness is required for them to instill good oral health in their children.

Key Words: *dental treatment, oral hygiene, fluoride, oral habits, occlusion.*

Introduction

The foundation for healthy permanent teeth in children and teenagers is laid during the first years of life. Poor oral hygiene and inadequate tooth brushing habits during the first two years of life can cause dental problems in future according to several studies[7]. Therefore, it is essential to establish proper oral hygiene early in life to ensure good oral health. Parents have to make their children aware about the importance of oral hygiene. But parents were not proactive in making sure that their children received regular dental care. Dental caries is the most common chronic disease of childhood that interferes with normal nutrition intake, speech, and daily routine activities[8,9].Parents' knowledge and attitudes about the importance of oral health care and their fears about dental treatment influenced their children's dental care [10]. Dental care has been systematically organized to improve dental health attitudes among children and the young [11]. For young children, the influence of parent's belief and behaviour is known to be strong [12-16]. Parents from low social status were found to be less accepting of the more "ultimate" techniques such as general anaesthesia [17]. The purpose of this study is to check the awareness of dental treatment among parents. It is essential for the parents to be aware of the current dental treatment milieu for their child's oral health care.

Material and Methods

This is a questionnaire based study on the awareness of the need for dental treatment for the children administered to the parents visiting Saveetha Dental College and hospitals. The participants include parents having children in both rural as well as urban side in Tamil Nadu. The questionnaire is filled in paper and pen method. After the data collection, statistical measurements are done with SPSS software version. Data is collected from a convenient sample of 150 participants under the supervision of dental students.

The questions mentioned in the Appendix have been asked to the parents through the questionnaire. The answers were marked according to their knowledge. Among 27 questions, seventeen questions are of yes or no type and the others are questions with appropriate answers given as choices.

Results

This study included a total of 150 parents visiting Saveetha dental college and hospitals with their children. Their child's ages ranged from five years to thirteen years with a mean of 8.85(S.D 2.49). The descriptive statistics of child's age of the participants are shown below in the Table 1.

General awareness about both dental and general health among the population is 105 of them are aware that the health of mouth and dentition impact the health of the body with the percentage of 70% and 24 of them felt that the health of mouth and dentition does not impact the general health of the body with percentage of 16%, 21 of them are not aware about this concept with the percentage of 14%. 55 of them are aware that the poor oral health is not good for cardiac health with the percentage of 36.7% and 73 of them felt that the poor oral health does not affect the cardiac health with percentage of 48.7%, 22 of them are not aware about this concept with the percentage of 14.7%. 75 of them are aware that the caries affect their child's dental aesthetics with the percentage of 50% and 38 of them felt that the caries affect your child's dental aesthetics with percentage of 25.3%, 37 of them are not aware about this concept with the percentage of 24.7%. 102 of them are aware that the treatment of toothache is as important as any organ in the body with the percentage of 68% and 32 of them felt that treatment of toothache is not as important as any organ in the body with percentage of 21.3%, 16 of them are not aware about this concept with the percentage of 10.7%. 60 of them care about their teeth than the body parts with the percentage of 40% and 73 of them does not care about their teeth than the body parts with percentage of 48.7%, 17 of them are not aware about this concept with the percentage of 11.3%. 65 of them are aware that the caries will affect their teeth appearance with the percentage of 43.3% and 54 of them felt that the caries will not affect their teeth appearance with percentage of 36.0%, 31 of them are not aware about this concept with the percentage of 20.7%. All data are enclosed as a form of table and graph below as Table 2 and Graph 1 respectively.

Awareness about caries attack among the population is 80 of them felt that the sweets will affects their child's dental health with the percentage of 53.3% and 41 of them felt that the sweets will not affect their child's dental health with percentage of 27.3%, 29 of them are not aware about this concept with the percentage of 19.3%.In case of soft drinks, 64 of them felt that the soft drink will affects their child's dental health with the percentage of 42.7% and 60 of them felt that soft drink will not affect their child's dental health with percentage of 40.0%, 26 of them are not aware about this concept with the percentage of 17.3%. For Ice creams,93 of them felt that ice cream will affects their child's dental health with the percentage of 62.0% and 27 of them felt that ice cream will not affect their child's dental health with percentage of 18.0%, 30 of them are not aware about this concept with the percentage of 20%. All datas are enclosed as a form of table and graph below as Table 3 and Graph 2 respectively.

The meaning of gum bleeding was asked to check their knowledge about the dental problems. In that, 11 of them said that it means a healthy gum with the percentage of 7.3% and 54 of them felt that it is an inflamed gum with percentage of 36.0%, 41 of them said that it means gum recession with the percentage of 27.3% and 44 of them are not aware about that dental term with the percentage of 29.3%. All datas are enclosed as a form of table and graph below as Table 4 and Graph 3 respectively.

The question is about how they will protect themselves from the gum bleeding. In that, 28 of them said that they will use tooth brush,paste and floss to protect themselves from gum bleeding with the percentage of 18.7% and 22 of them said that they will use soft food to protect them from gum bleeding with percentage of 14.7%, 73 of them said that they will consult doctor for gum bleeding with the percentage of 48.7% and 27 of them are not aware about that knowledge of gum bleeding with the percentage of 18.0%. All data’s are enclosed as a form of table and graph below as Table 5 and Graph 4 respectively.

The meaning of dental plaque was asked to check their knowledge about the dental problems. In that, 33 of them said that it means a soft deposit on the tooth surface with the percentage of 22.0% and 34 of them felt that it is an heavy deposit on the tooth surface with the percentage of 22.7%, 40 of them said that it means tooth discolouration with the percentage of 26.7%

and 43 of them are not aware about that dental term with the percentage of 28.7%. All data's are enclosed as a form of table and graph below as Table 6 and Graph 5 respectively.

The question is about what does the dental plaque leads to. In that, 33 of them said that it will leads to inflammation of gum with the percentage of 22.0% and 32 of them said that it will leads to staining of the teeth with percentage of 21.3%, 38 of them said that it will leads to dental caries with the percentage of 25.3% and 47 of them are not aware about that knowledge of dental plaque with the percentage of 31.3%. All data's are enclosed as a form of table and graph below as Table 7 and Graph 6 respectively.

Awareness about the brushing habit and role of parents in their child's oral hygiene among the population is 79 of them said that their children brushes twice a day with the percentage of 52.7% and 60 of them said that their children do not brush their teeth twice a day with the percentage of 40.0%, 11 of them do not care about that with the percentage of 7.3%. The next question is about whether their children are using tooth brush and paste for brushing their teeth to check that they are knowledgeable about their child's dental hygiene. In that, 96 of them said that their children are using tooth brush and paste for brushing with the percentage of 64.0% and 44 of them said that their children are not using tooth brush and paste for brushing with the percentage of 29.3%, 10 of them are not aware about that with the percentage of 6.7%. The question is asked to the participants about does brushing will prevent dental caries. In that, 70 of them said that brushing will prevent dental caries with the percentage of 46.7% and 43 of them said that brushing will not prevent dental caries with percentage of 28.7%, 37 of them are not aware about this concept with the percentage of 24.7%. The most important question is asked to parents that they supervisetheir children while brushing or not. In that, 98 of them said that they are supervising their children while brushing with the percentage of 65.3% and 44 of them said that they are not supervising their children while brushing with the percentage of 29.3%, 8 of them are not aware about this concept with the percentage of 5.3%. 48 of them felt that fluoride will strengthen their teeth with the percentage of 32.0% and 43 of them felt that fluoride will not strengthen their teeth with percentage of 28.7%, 59 of them are not aware about this concept with the percentage of 39.3%. 57 of them felt that they can decide the treatment whatever they need with the percentage of 38.0% and 73 of them felt they cannot decide the treatment whatever they need

with percentage of 48.7%, 20 of them are not aware about this concept with the percentage of 13.3%. All data are enclosed as a form of table and graph below as Table 8 and Graph 7 respectively.

The question is about how long their children are brushing their teeth. In that, 30 of them said that their children are brushing their teeth less than 1 min with the percentage of 20.0% and 56 of them said that their children are brushing their teeth 2 min with percentage of 37.3%, 43 of them said that their children are brushing more than 2 min with the percentage of 28.7% and 21 of them will not supervise their children while they are brushing with the percentage of 14.0%. All data's are enclosed as a form of table and graph below as Table 9 and Graph 8 respectively.

The question is about what their children used for brushing their teeth. In that,101 of them said that their children are using tooth brush and paste along with floss for brushing their teeth with the percentage of 67.3% and 23 of them said that their children are using mouth wash instead of brushing with percentage of 15.3%, 18 of them said that their children are using tooth picks instead of brushing with the percentage of 12.0% and 8 of them will not aware about what their children are using for brushing with the percentage of 5.3%. All data's are enclosed as a form of table and graph below as Table 10 and Graph 9 respectively.

The question is about how often they will change their toothbrush. In that, 44 of them said that they will change their tooth brush in the interval of 3 months with the percentage of 29.3% and 39 of them said that that they will change their tooth brush in the interval of 6 months with percentage of 26.0%, 44 of them said that that they will change their tooth brush only when damage occurs with the percentage of 29.3% and 23 of them will not change their brush at anytime with the percentage of 15.3%. All data's are enclosed as a form of table and graph below as Table 11 and Graph 10 respectively.

The question is about how often they will visit their dentist. In that, 41 of them said that they will regularly visit their dentist with the percentage of 27.3% and 62 of them said that that they will visit their dentist only during pain with percentage of 41.3%, 23 of them said that they will visit their dentist occasionally with the percentage of 15.3% and 24 of them will

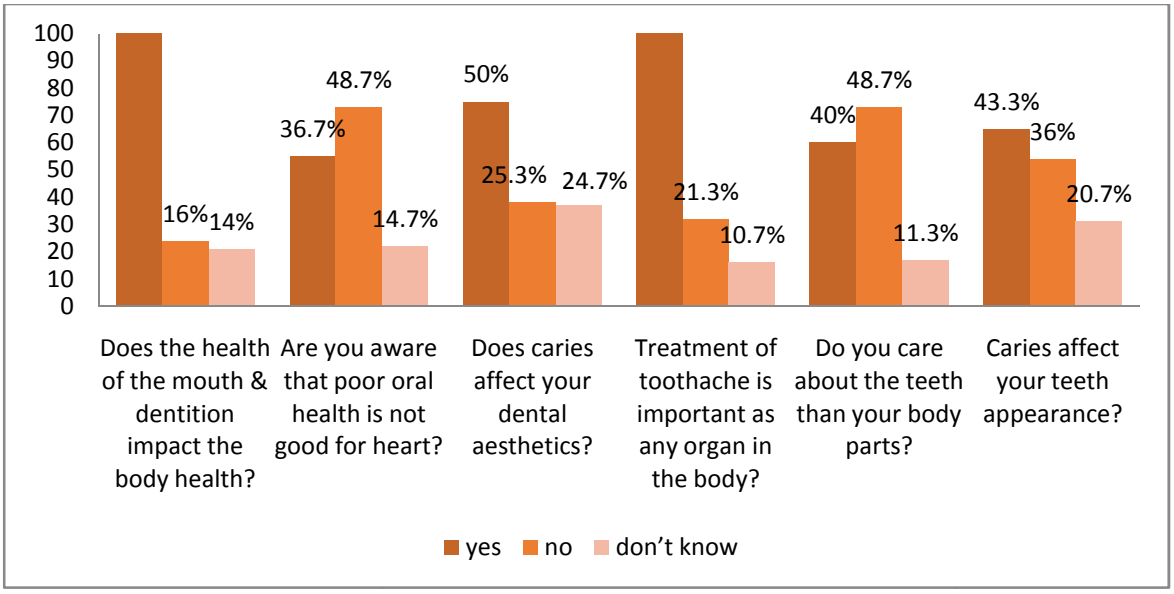
never visit the dentist with the percentage of 16.0%. All data's are enclosed as a form of table and graph below as Table 12 and Graph 11 respectively.

63 of them are aware that regular visit to the dentist is necessary with the percentage of 42.0% and 46 of them felt that regular visit to the dentist is not necessary with percentage of 30.7%, 41 of them are not aware that the regular visit to the dentist is necessary with the percentage of 27.3%. 68 of them said that dentist always explain procedures before treatment with the percentage of 45.3% and 34 of them felt that the dentist will not explain procedures before treatment with percentage of 22.7%, 48 of them are not aware as they will never visit the dentist with the percentage of 32.0%. All data's are enclosed as a form of table and graph below as Table 13 and Graph 12 respectively.

The question is about when they visited the dentist recently. In that, 48 of them said that they have visited the dentist 6 months before with the percentage of 32.0% and 27 of them said that they have visited the dentist 1-2 years before with percentage of 18.0%, 26 of them said that they have visited the dentist more than 2 years before with the percentage of 17.3% and 49 of them will never visit the dentist with the percentage of 32.7%. All data's are enclosed as a form of table and graph below as Table 14 and Graph 13 respectively.

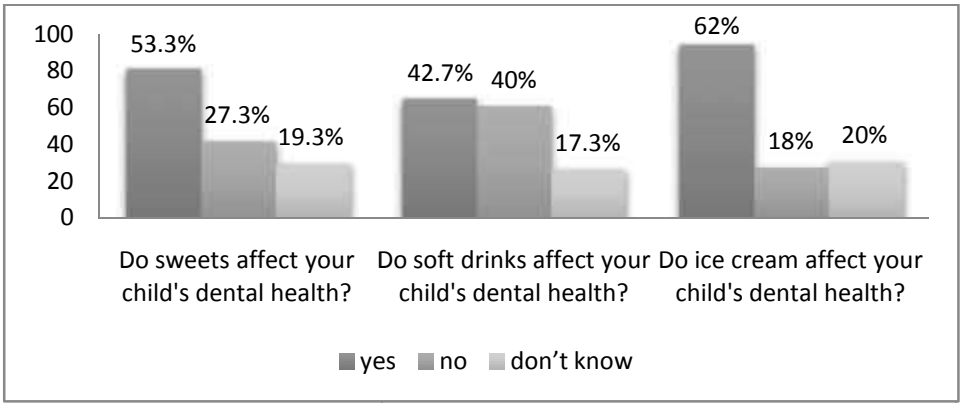
The question is about reason behind not visiting the dentist. In that, 27 of them said that they are afraid of needle with the percentage of 18.0 % and 51 of them said that they have no time to visit the dentist with percentage of 34.0%, 35 of them said that they are not interested to visit the dentist with the percentage of 23.3% and 37 of them are not aware in visiting the dentist with the percentage of 24.7%. All data's are enclosed as a form of table and graph below as Table 15 and Graph 14 respectively.

Graph 1: General awareness about both the dental and general health.



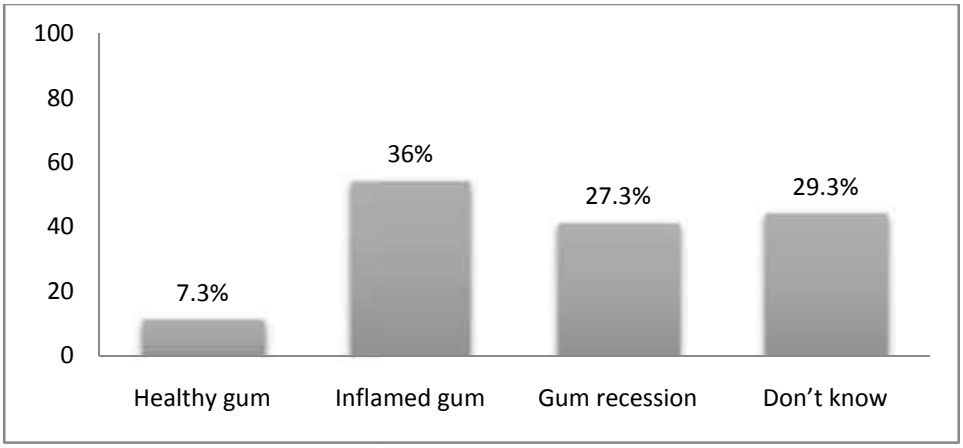
70% parents thought that body health have impact on oral health and dentition, 36.7% parents have an opinion that poor oral health affects the heart, 50% parents thought that caries affects their aesthetics and 68% parents thought that treatment for toothache is important.

Graph2: Awareness about the Caries attack.



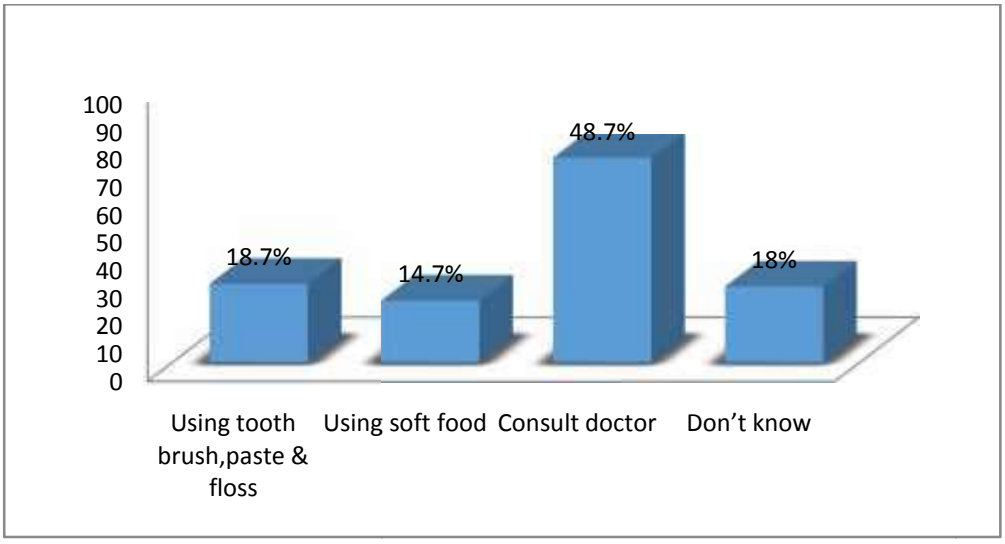
53.3% parents think that sweets, 42.7% parents think that soft drinks, 62% parents think that ice cream affects their child's oral health.

Graph 3: Knowledge about the term Gum bleeding.



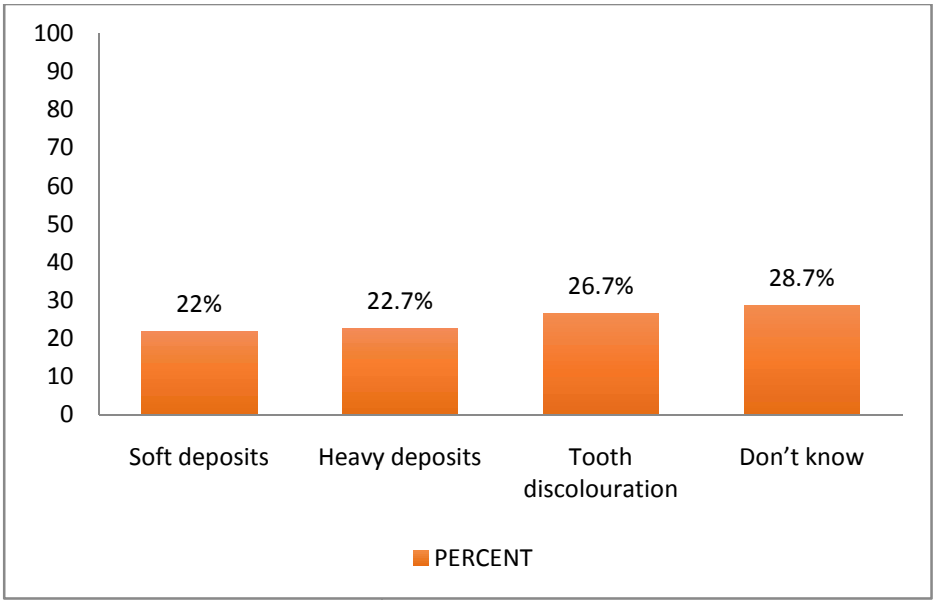
Knowledge about the term gum bleeding was significantly known only by 36% study population.

Graph 4: Knowledge about the Gum bleeding treatment.



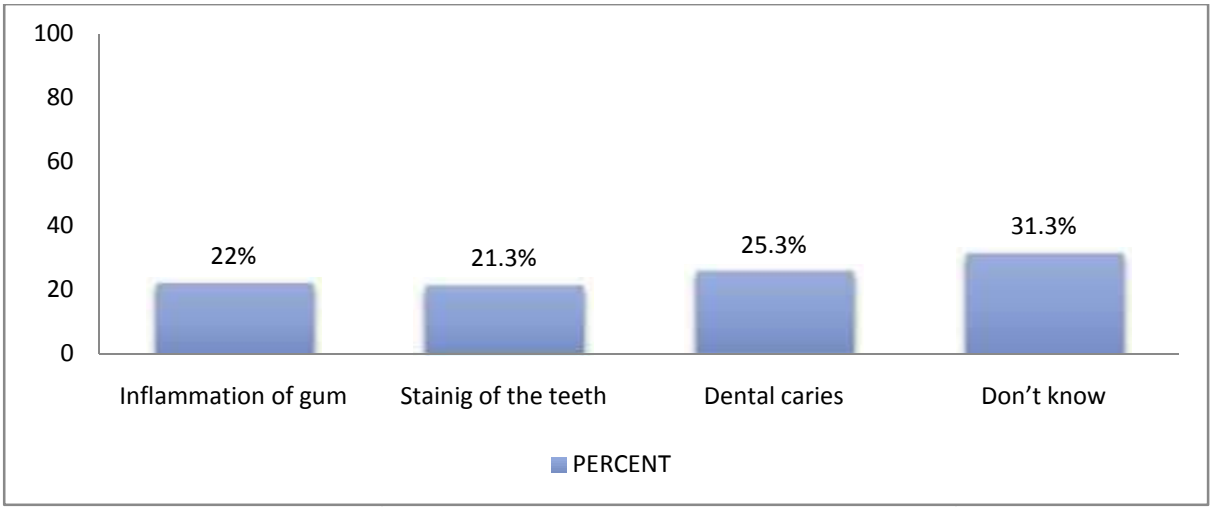
48.7% parents only think that for the treatment of gum bleeding should consult a doctor, 33.4% parents thinks that using tooth brush, paste, floss, soft brush will solve gum bleeding.

Graph 5: Knowledge about the term Plaque.



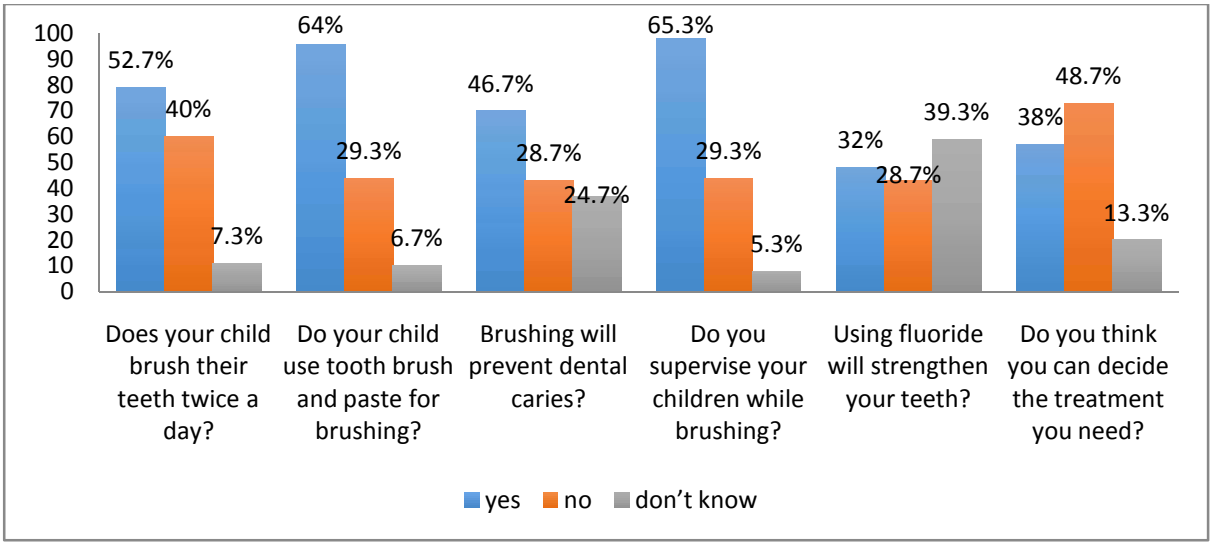
Knowledge about the term plaque was significantly known by 22% as soft deposits.

Graph 6: Knowledge about the Plaque etiology.



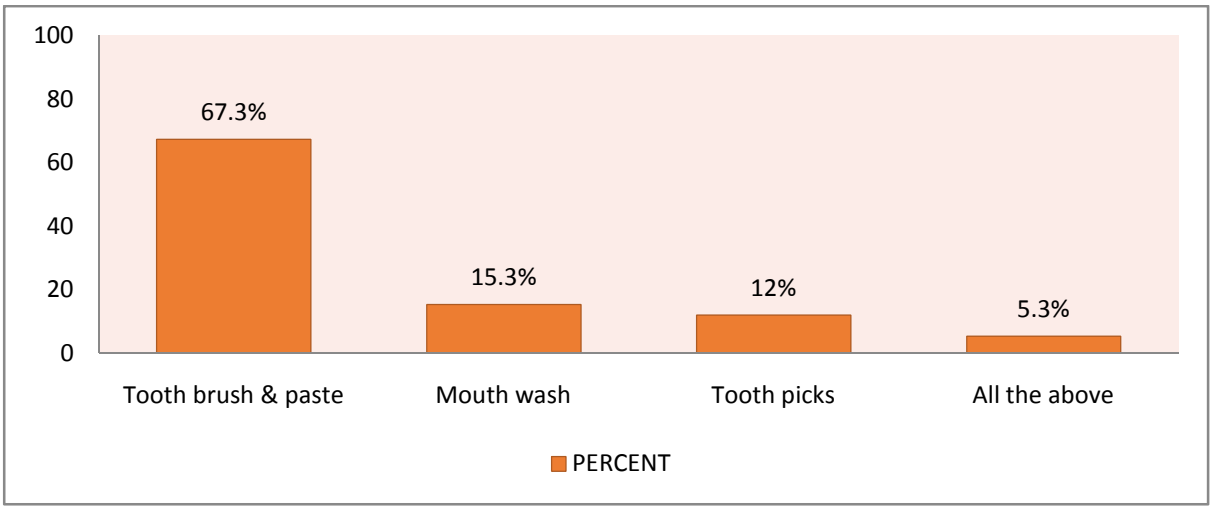
25.3% parents think that plaque causes dental caries and 22% parents think that it causes inflammation of gum and 31.3% parents had no idea about it.

Graph 7: Awareness about the brushing habits and the role of parents in their child's oral hygiene.



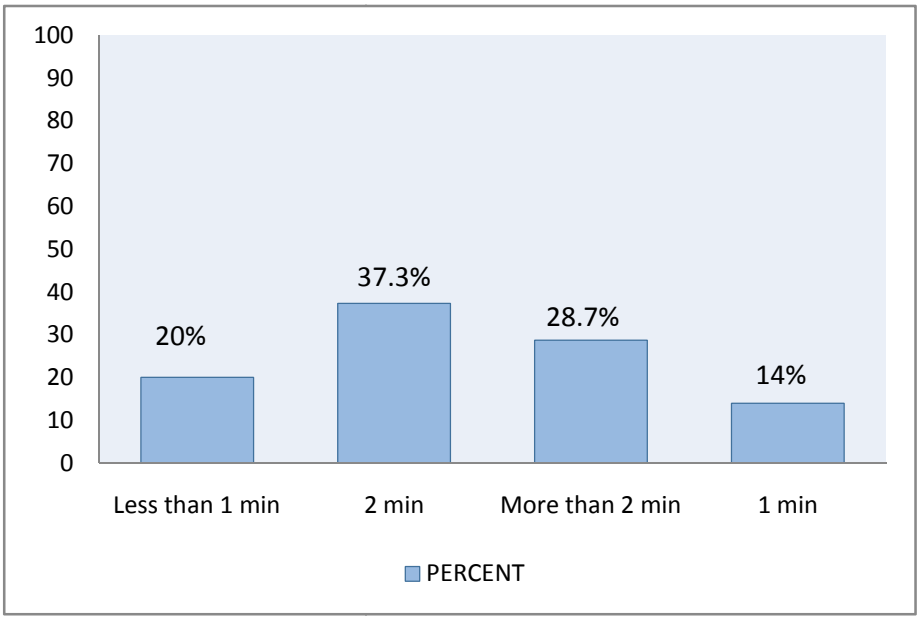
52.7% study population said that their child brushes twice daily and 64% population uses tooth brush and paste for brushing, 46.7% population believe that brushing will prevent caries, 65.3% parents supervise their children during brushing, 32% population believe that fluoride will strengthen the teeth and 48.7% population will never decide their treatment on their own.

Graph 8: Knowledge about the oral habits of their children.



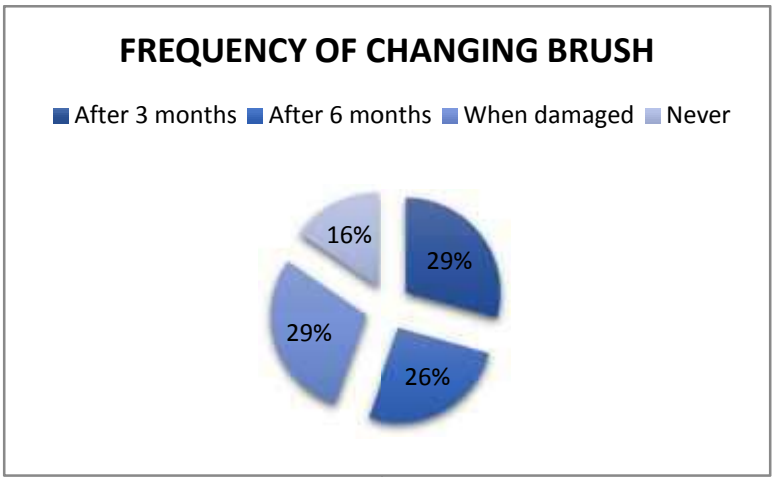
67.3% uses tooth brush and paste to maintain their oral hygiene and 12% uses tooth picks to clean their teeth.

Graph 9: Knowledge about the brushing habits of their children.



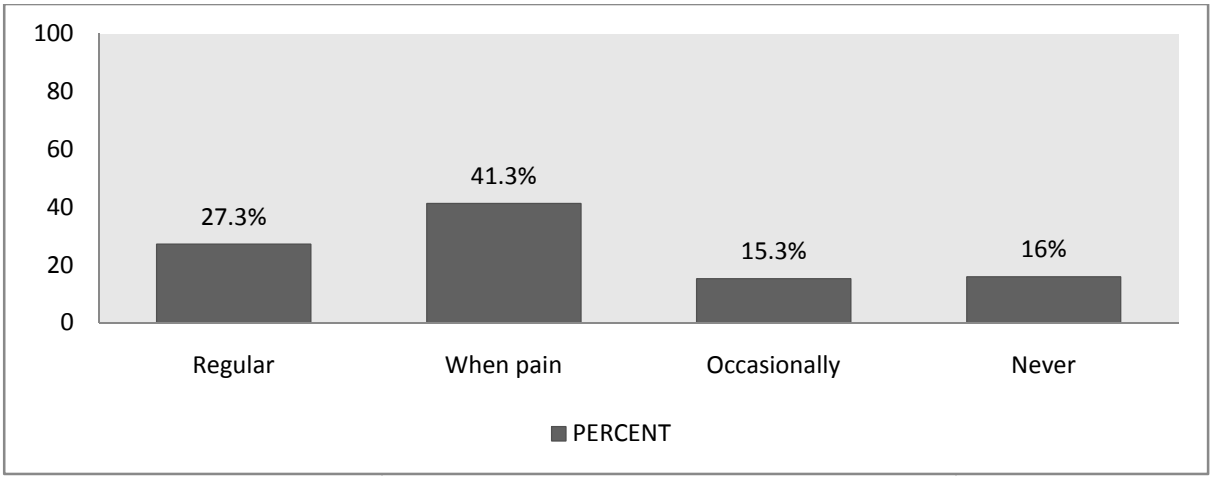
Only 37.3% parents teach their child to brush for 2 minutes.

Graph 10: About the frequency of changing the tooth brush of their child.



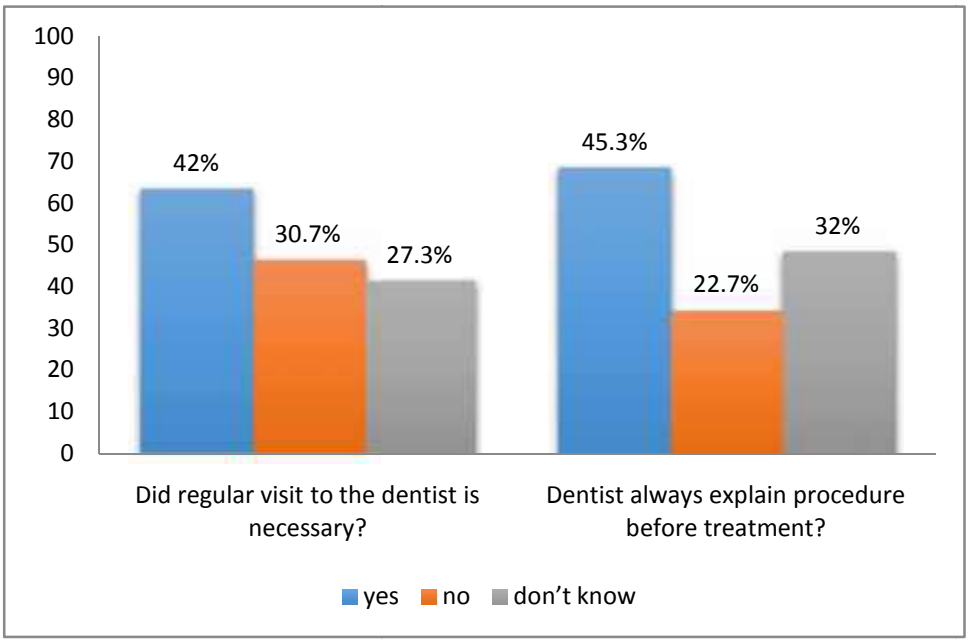
Only 55% study population care on their children dental health at regular intervals.

Graph 11: Knowledge about the dental visit.



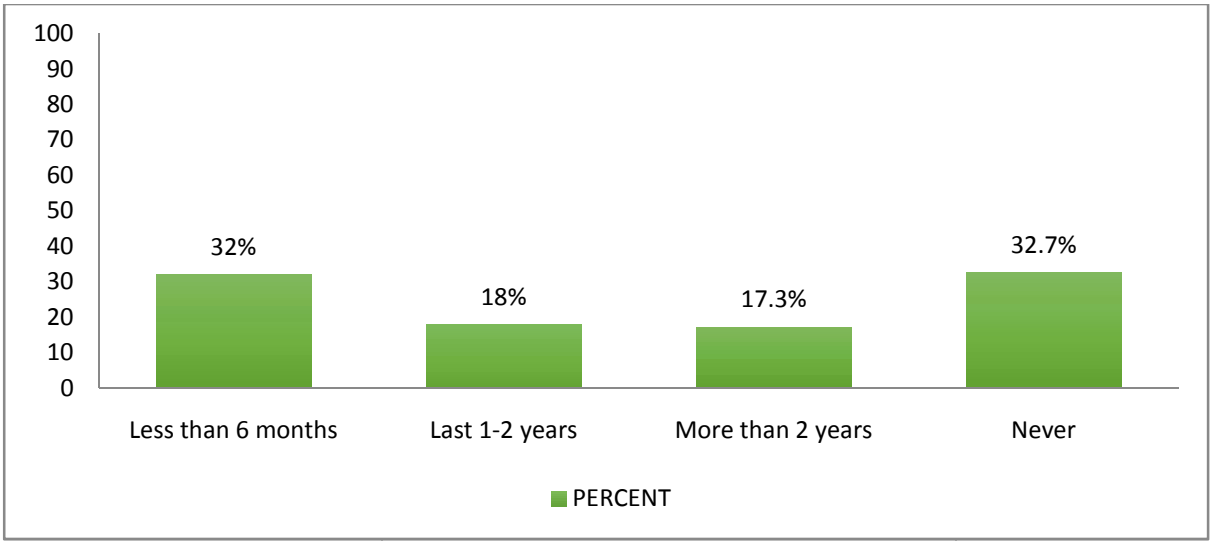
Only 27.3% study population think that regular dental check-up is important for proper oral health.

Graph 12: Knowledge about the importance of dental visit.



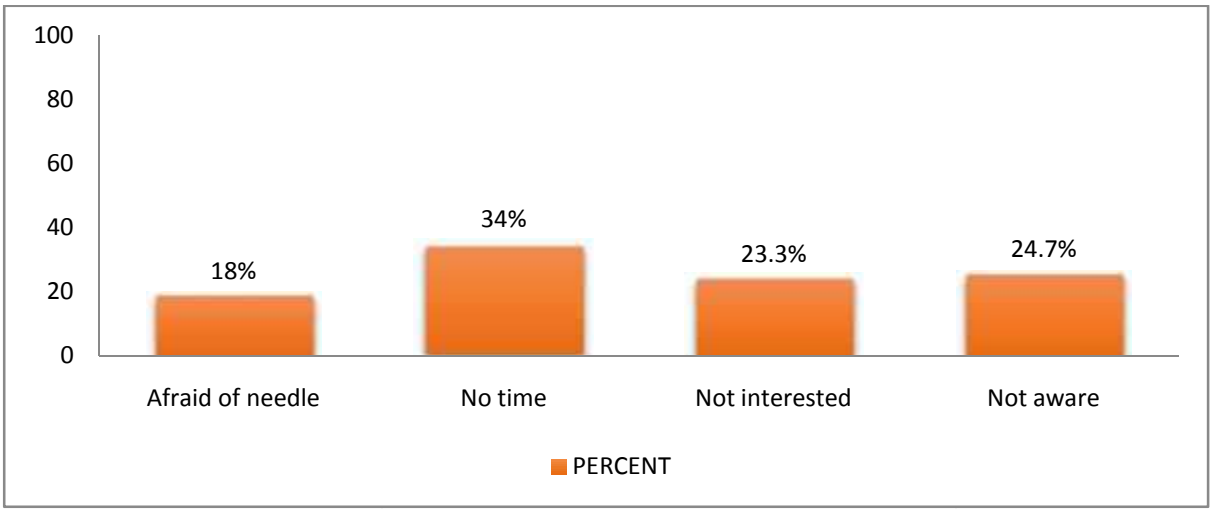
42% parents think that regular visit to dentist is important and 45.3% believe that the dentist will explain the procedure before treatment.

Graph 13: Knowledge about the regular visit to the dentist.



32% study population think that regular dental visit less than months is important.

Graph 14: Reason behind not visiting the dentist.



18% population not visiting the dentist because of needle fear and 34% is because of no time for the visit.

Figure.1: Questionnaire of the Study

Discussion

This study provides the awareness about dental treatment for the children administered to the parents. The result showed that the parents are aware to a certain extent about the dental treatments and their children's oral hygiene. But still the parents seem to be not in touch with the oral symptoms of their children [18]. In another study, they found that parents who did not obtain dental care for themselves were less likely to bring their children for dental care [19]. A recent study states that parental knowledge and awareness are necessary prerequisite for

change in behaviour, including behaviour related to health and disease prevention [20]. Most parents believed that inadequate tooth cleaning and sweets,snacks and drinks are contributed to early child caries [21]. According to this study, 53.37%,42.7% and 62.0% parents are aware about the prevalence of caries due to sweets,ice cream and drinks. 50% and 43.3% people are aware that the caries will affect their child's teeth appearance. 46.7% of the parents believe that brushing will prevent dental caries.

Exposure to fluoride is known to be protective against caries development [22,23]. According to this study, only 32.0% of the parents felt that fluoride will strengthen their teeth. Parents must be aware of the appropriate amounts of toothpaste to apply on the brush or cleaning cloth [21]. In this study, only 64.0% of the children using tooth brush and paste for cleaning their teeth and 15.3% of the children using mouth wash instead of brushing. An another study among Hong Kong children stated that among who had a toothbrush habit, only 49% are reported using toothpaste [27].

A recent survey found that a high percentage of the children in their study brush their teeth at least once daily although this effort was not fully organized or supported by parents [9]. According to this study, 52.7% of the children brush their teeth twice a day and 40.0% of them are not brushing their teeth twice a day.

In this study, 65.3% of the parents supervise their children while brushing. But a finding by Lee, who reported that only 45% of parents helped their children to brush their teeth [26].

Parents' failure to organize or support their children's tooth brushing efforts coincided with findings from previous studies that reported lack of acceptable levels of knowledge and awareness of periodontal problems among Jordanian adults [24,25]. The participants demonstrated positive attitudes towards their dentists and high awareness of the link between oral health and systemic well-being [21]. In this study, 70% of the parents felt that the health of mouth and dentition impact the health of the body and 42.0% of the parents have positive attitudes towards the dental visit and dental treatments.

Lack of parental encouragement and advice to visit the dentist might also contribute to the irregular dental attendance. Lack of parents' regular dental attendance might be reflected in their children [21]. According to this study, 58% of the parents are not aware about regular dental visit. Fear of dental treatments was found to be high among the school children in North Jordan [9]. In this study, 18.0 % of the children are afraid of needle. It can also be a reason for lack of regular dental attendance of the parents and children.

Consequently, dental health education programs that aim to improve oral health practice among the population are very important. Hence, there is a need for educational programs to improve the oral health practice, knowledge, and attitudes of the general population [21].

Conclusion

This study shows that the importance of parental knowledge on their child's dental health. Parents are not fully familiar with oral hygiene techniques and dental treatment methods but more awareness is required for them to instill good oral health in their children. The results of this study will be helpful for the health care providers to conduct more public education programs about oral hygiene in the future. The importance of parental support in managing the oral hygiene of their children is mentioned.

Abstract

Introduction: Most patients particularly dentists who present with neck pain have “non-specific (simple) neck pain, “where symptoms have a postural or mechanical basis. Aetiological factors are usually multifactorial, including poor posture, anxiety, depression, neck strain, and sporting or occupational activities. When mechanical factors are prominent, the condition is often referred to as “cervical spondylosis,” although the term is often applied to all non-specific neck pain. The aim of this study was to find the frequency of neck pain among dentists.

Materials and Methods:A cross sectional survey was carried out by convenience sampling in different dental hospitals of Chennai. A Total of 100 questionnaires were filled by dentists. The data was collected using a questionnaire focusing on back position, travel to clinic, hours of practice, assisting hands during practice, duration of sleep,time spent on electronic gadgets, dizziness or discomfort after work, duration of pain and if any treatment undergoing. Qualitative variables were represented as percentages and bar charts. Descriptive statistics that is mean and standard deviation were used to represent the total score.

Results: Neck pain was the most common complaint. 67% were males, 33% were females. 34% are practising dentistry above 20 years, 32% above 15 years, 26% above 10 years, and 8% above 5 years. The position of practice is that 96% of the dentists practise sitting position and the rest 4% practise standing position. 72% of dentists uses electronic gadgets more than 3 hrs, 18% of dentists uses for 3 hrs and 10 of them uses lesser than 3 hrs. 90% of dentists faces discomfort around neck and shoulder after work whereas the rest10% do not.

Conclusion: The frequency of neck pain and neck disability in dentists seemed to be high and is an area that needs further deliberation. The majority of working dentists have musculo-skeletal symptoms in the neck.

Key Words:*cervical spondylosis, dentists, neck pain, posture, Ergonomics.*

Introduction

Most patients who present with neck pain have “non-specific (simple) neck pain,” where symptoms have a postural or mechanical basis. Aetiological factors are poorly understood [(1)] and are usually multifactorial, including poor posture, anxiety, depression, neck strain, and sporting or occupational activities.[(2)] Neck pain after whiplash injury also fits into this category, provided no bony injury or neurological deficit is present.[(3)] When mechanical factors are prominent, the condition is often referred to as “cervical spondylosis,” although the term is often applied to all non-specific neck pain. Mechanical and degenerative factors are more likely to be present in chronic neck pain.

In cervical spondylosis, degenerative changes start in the intervertebral discs with osteophyte formation and involvement of adjacent soft tissue structures. Many people over 30 show similar abnormalities on plain radiographs of the cervical spine, however, so the boundary between normal ageing and disease is difficult to define.[(4)]

Even severe degenerative changes are often asymptomatic, but can lead to neck pain, stiffness, or neurological complications. Neck pain is an ache or discomfort in anatomical area between occiput and 3rd thoracic vertebra and laterally between middle margin of scapula [(5)]. Neck pain is considered to be chronic if the patient suffered more than 3 months [(6,7)].

The prevalence for neck pain varies between 16.7% and 75.1% in the general population [(8)]. Neck pain may be caused by; spondylosis, spinal stenosis, disc herniation, stress, poor posture, prolonged posture [(9,10)].

Symptoms of neck pain may include; neck soreness and headache, pain around shoulder blades, arm complaints (pain, numbness or weakness). Dental profession is one of the occupational risk factors of neck pain [(5,11)]. Studies showed that neck pain starts early in dental career even during educational training [(12, 13).]

In a recent study, 54.4% of dentists in K.S.A. had neck pain, 21.69% of them drop out of job [(14).] Recently, it was shown that there is a strong relation between work duration and neck pain in the staff of dental school [(15,16).] Another study reported that increasing weekly work hours has little effect on neck pain [(14,17).]

The most common cause of neck pain in dentists is prolonged work posture which makes high load on muscles of neck and shoulder region (trapezius more than splenius)[(16).] The main working posture of dentist is in sitting, with neck flexion, shoulder elevation and upper extremity abduction and his patient supine [(14,15,17,18).]

Materials and Methods

A cross sectional survey was carried out by convenience sampling in different dental hospitals of Chennai. A Total of 100 questionnaires were filled by dentists, in which 67 were males and 33 were females. The data was collected using a questionnaire focusing on socio-demographic data, back position, travel to clinic, consultation per day, hours of practice, assisting hands during practice, specialisation ,duration of sleep, type of mattresses and pillows, time spent on electronic gadgets, dizziness or discomfort after work, duration of pain and if any treatment undergoing. Qualitative variables were represented as percentages and bar charts. Descriptive statistics that is mean and standard deviation were used to represent the total score.

Discussion

67% were males, 33% were females. 30% of people were from 30-35 age group and 40-45 age group each, 25%were from 35-40 age group, 10%were from 45-50 age group, and 5%were >50 age group. 34% are practising dentistry above 20 years, 32% above 15 years, 26% above 10 years, and 8% above 5 years. 50% of dentists use4 wheeler for travel, 45% of dentists use 2 wheeler to travel and 5% uses 3 wheeler for travel. Among these dentists, 55% of dentists works 8hrs, 33% of dentists work more than 8 hrs and 12% of dentists work 4 hrs a day.

World Health Organization defines musculoskeletal disorders (MSD) as problems of muscles, tendons, joints, inter-vertebral discs, peripheral nerves and vascular system. It is not directly a result of acute or prompt incidence but mounting slowly and frequently. During past many years it has been reported that MSD have increased in routine work. [21,22]. MSD are a frequent occurring throughout the globe and are the most common reason of chronic pain as well as disability effecting millions of people. Literature shows prevalence ratio of neck pain is high among dentists. World Health Organization describes work related musculoskeletal diseases being dependent on many factors including but not exclusive to structural, psychosocial and socio-cultural variables.

The second most common MSD in dentistry is neck pain. [23] The symptoms of MSD are categorized by occurrence of uneasiness, disablement and pain for a prolonged time period in the soft tissue structures. [24] Dentistry demands high accuracy and is frequently performed with the cervical spine being rotated and

flexed forward. This produces high static load in the neck region. Extended duration of static load and repetitive movements can result in neck pain, tension neck syndrome, muscle imbalance or cervical instability. [25]. As the oral cavity is narrow, dentists have a constrained visual field and restricted movement of neck and back leading to pain in these regions. [26]. The forward flexion of head and neck leads to cervical spine instability that causes straightening of its curvature. There is an increased risk of disc herniation and prolapse due to the lengthening and shortening of particular muscles, tendons and ligaments. Inflammation of neck muscles ensues due to overload and an unstable neck posture. [25].

As a result of tension neck syndrome (TNS), patients can have some symptoms like rigidity, pain and soreness in the region of trapezius. This is frequently associated with muscular spasm or tenderness or trigger points. It is not necessary that all symptoms must be localized in the region of neck but this can radiate into arms, skull and between shoulder blades. The most common symptoms of TNS is headache. The primary causative factor for TNS is poor posture with forward head position. The associated factors with neck pain include forward head posture or increased working hours. The symptoms of neck pain can be worse in professions where work demands extended head posture and utilization of muscles with reduced endurance that stabilize the neck [26]. Risk factors for this problem include high demands of job, poor job control, minimum social support and some personal characteristics [27]. Age related changes in vertebral column, its shape, weakness of muscles, poor practice posture / techniques of lifting and mechanical pressure are factors that contribute in neck and back pain [28]. Cervico-genic headache is a pain that refers from cervical spine to the head. Physiology of this pain is conjunction between trigeminal afferents and upper three cervical spinal nerves afferents[29].Trapezius pain is the classic stress pain and it is the most common musculoskeletal disorder [31].Neck pain is a common in the general population, with 70% of individuals affected some time in their lives [35]. Many researchers have proven scientifically and has also reported that protracted shoulder might lead to shoulder malposition, which may increase the subacromialimpingement [32]. Low Back Ache (LBA) is the second most common cause of disability [33].

The term work-related musculoskeletal disorders (MSDs) refers to the disorders to which the work environment contributes significantly to musculoskeletal disorders that are made worse or longer lasting by work conditions or workplace risk factors. Some of the examples of such workplace risk factors include jobs requiring repetitive, forceful or prolonged exertions of the hands, frequent or heavy lifting, pushing or pulling, or carrying of heavy objects and prolonged awkward postures. The level of risk depends on the intensity, frequency and duration of the exposure to these conditions. A WMSD can be defined as a condition wherein work-related tasks affect the nerves, tendons, muscles and supporting structures. Conditions can vary from mild recurrent symptoms to severe and incapacitating. Early symptoms of WMSDs include pain, swelling, tenderness, numbness, tingling sensation and loss of strength [30].Grip

strength is a force applied by the hand to pull on or suspend from objects and is a specific part of hand strength. It is the muscle power and force that can be generated by the hand.

Mechanical Neck pain may arise due to muscular tightness in both the neck and upper back. Exercise plus joint mobilization and manipulation has been found to be beneficial in both acute and chronic neck disorders. Neither mobilization nor manipulation without exercise however has been found to be helpful. Mobilization is equivalent to manipulation. Here two varieties of techniques are carried out in treating the neck pain. Recently evidence has begun to emerge for the use of manual therapy, specifically thrust manipulation procedures, directed at the thoracic spine in people with neck pain. Further decrease in the mobility of the thoracic spine has been shown to be related to the presence of neck pain symptoms.[34]

Coming to the consultation, 68% goes for consultation and the rest 32% do not. The most important part of back posture where 70% of the dentists do not use back rest whereas 30% uses back rest. Single handed dentistry is been practised by 25% of dentists, two handed dentistry is been practised by 65% of the dentists, and 10% of the dentists practice four handed dentistry. The position of practice is that 96% of the dentists practise sitting position and the rest 4% practise standing position. Among these dentists, dental surgeons were 20%, 10% periodontists,53% endodontists, 12% were prosthodontists and 5% were pedodontists. 61% of dentists sleep lesser than 7 hrs, 30%of dentists sleep 7 hrs, and the rest 9% sleeps greater than 7 hrs.

11% of dentists prefer hard mattresses and the rest 89% prefers soft type of mattresses. 62% of dentists use only one pillow during sleep and 38% of dentists uses 2 pillows for sleep. 72% of dentists uses electronic gadgets more than 3 hrs, 18% of dentists uses for 3 hrs and 10 of them uses lesser than 3 hrs. 86% of the dentists experiences dizziness during up and down movement of neck and 14% of dentists are comfortable. 90% of dentists face discomfort around neck and shoulder after work whereas the rest10% do not.

Of which 45% of dentists experiences pain >2 hrs, 20% of the dentists experiences pain >4 hrs, 35% of dentists experiences pain <2 hrs. For relief, 10% of dentists take medications, 30% of dentists undergo physiotherapy, 15% of dentists practise yoga, 35% of dentists exercise regularly, and 10% do not undergo any treatment.

Conclusion

Dentists are at the high risk of musculoskeletal symptoms in the neck. The reason for it is the position of work is difficult with cervical spine in flexion and rotation, repetitive procedure which demand accuracy; these problems can be overcome by some preventive measures like dentist’s chair is properly constructed

and the design of work unit should be appropriate, educate the dentist regarding ergonomics and should improve the work organization.[19]. Dentistry is physically and mentally a demanding profession. The physical characteristics include good psychomotor skills, hearing, visual quality, manual skill and ability to maintain good posture during work for an extended period of time. In case the dentist fails to adjust to a particular working environment, he / she can incur injury or disability. Hence dentists are at risk of work-related diseases / injuries e.g. allergies, systemic diseases, loss of hearing and musculoskeletal problems[20].
