Abstract

Introduction: Coronary artery disease plays major role in the European and developing countries. Indian prevalence also shows a high risk of coronary artery disease. Change in the sedentary life style, unhealthy diet, stress etc. leads to high cholesterol levels with added risk factors such as smoking, diabetes mellitus thus making the individuals more prone for coronary artery disease. With the current scenario change in your working habits improper eating habits, decreased physical inactivity, stressful lifestyle have led to early evolution of coronary artery disease. Thus the aim of this article was to retrospectively analyze 50 CAD patients to reassess the risk factors for its development and to calculate the number of vessels involved in blockage through echo cardiogram.

Materials and Methods: The clinical data of 50 CAD Patients who underwent treatment at Saveetha Medical College was used to derive at the number of vessel blockage with gender, age, diabetes, obesity and habit of smoking through Echo Cardiogram.

Results:Our study reveals that out of 50 CAD patients with 31 men and 19 women. 25 patients are affected with single vessel disease, 9 patients are affected with double vessel disease, and 16 patients are affected with triple vessel disease. Smokers are the most affected with 22 in numbers amongst the male. The age group spread across 35 to 60 years(13). In total 45 patients are with diabetics

Conclusion: Cardiovascular diseases and CAD remain the leading cause of mortality in the world. Thus, preventing ourselves from such diseases rather than treating the deadly ones is much better and we have to join hands in abolishing such emerging deadly diseases in the future.

Key Words: *Coronary Artery Disease, atherosclerotic plaque, thrombus, Smoking, , Diabetes Mellitus, Hypertension, Obesity, , Stress, Genetics.*

Introduction

Indian youngsters are on the high risk of Coronary Artery Disease according to various research and articles published in the recent times which was mainly due to factors of Smoking(11), high cholesterol levels, Diabetes Mellitus, Hypertension(16), Obesity, Unhealthy food habits, Physical inactivity(17), Stress, Genetics.(1) This has driven me to choose a study on the above CAD to evaluate the major contributors which can be an eye opener and also help to create an awareness to the prospective CAD patients, which will help them to change their life style to avoid major threat to their life. This article highlights the significance of the Coronary artery disease where we have chosen 50 CAD patients to calculate the number of vessels involved with the aid of Echo Cardiogram.

CAD refers to disease of the coronary arteries. Coronary arteries carry blood and oxygen to the heart; therefore any disease which affects the coronary arteries deprives the heart of oxygen — the extreme form of this deprivation occurs during myocardial infarction (heart attack)(9).Built of fatty material is called as atherosclerotic plaque which transforms in to thrombus which stays in the arteries and blocks the movement of blood platelets (2). The precious asset of our nation is its young population; ironically, it is becoming the most vulnerable to CAD and myocardial infarction (MI).

Four people die of heart attack every minute in India and the age group is mainly between 30 and 50.Twenty-five per cent of heart attack deaths occur in people less than 40.Nine hundred people under 30 die due to heart disease in India every day (2).Lack of awarenessin rural and urban poor are more susceptible because they tend to ignore the disease due to poor access to health care, high cost of treatment, social stigma and illiteracy(6).

Seeking treatment will also mean missing wages and reduced productivity.The statistics in our country may represent only the tip of the iceberg. Because of poor reporting of cases and incomplete collection of statistical data, the actual figures for young Indians suffering from coronary artery disease may be much more than that reported in studies. Several lines of evidenced suggests that clinical depression may be a risk factor for coronary artery disease (12).

Salient Features of the Coronary Artery Disease (CAD) Epidemic in India

- India topped the world with 1 531 534 cardiovascular disease-related deaths in the

year 2002

- Median age of first heart attack in Indians is 53 years.
- Incidence of CAD in young Indians is about 12%–16%, which is higher than any other ethnic group(8).
- About 5%–10% of heart attacks occur in Indian men and women younger than 40 years
- Age-standardized estimates for disability-adjusted life-years lost due to CAD per 1000 population in India are three times higher than in developed countries(1).
- Depression has been found to be an important cause for CAD among women(14).
- The chances of CAD due to genetic is estimated at 50 – 60%(15)
- Dyslipidemia is one of the major contributor in CAD(18)

Materials and Methods

The clinical data of 50 CAD Patients who underwent treatment at Saveetha Medical College was used to derive at the number of vessel blockage with gender, age, diabetes, obesity and habit of smoking through Echo Cardiogram.

The clinical data of 50 CAD patients were taken for this research which comprises patients with background of Smoking, high cholesterol levels, Diabetes Mellitus, Hypertension, Obesity, Unhealthy food habits, Physical inactivity, Stress, Genetics in the age group of 35 – 60 years of both genders. These patients were diagnosed from SaveethaMedical College and Hospitals.

The patients were grouped based on demographic data of age, gender, men with habit of smoking, diabetes, obesity and age group. The vessel blockage identification was done through Echo Cardiogram. Obesity was calculated using body mass index(BMI), the age and gender were estimated through graph and pie chart estimation. The smoking habit and diabetes mellitus risk factors were estimated through pie charts.

Figure 2: Pathophysiology of Atherosclerosis

The heart muscle relies on a steady flow of oxygen-rich blood to nourish it and keep it pumping. During a heart attack, that blood flow is interrupted by a blockage in an artery. Without blood, the area of heart fed by the affected artery begins to die and scar tissue forms in the area.(43) Atherosclerosis is an immuno-inflammatory disease which occurs mainly in the large and medium sized arteries. Endothelial injury is the prime step in the formation of atheroma. After endothelial injury, the surface adhesion molecules are increased and it leads to monocyte adhesion by the expression of monocyte chemoattractant protein-1 (MCP-1).These monocytes are converted into tissue macrophages in the intima layer. The activated macrophages secrete various cytokines. Cytokines in turn stimulate the endothelial cells. Activated macrophages also have the property of capturing low density lipoproteins which undergo progressive oxidation and are no longer available for β oxidation of fatty acids to produce energy. Subsequently, there is a formation of lipid peroxidises and accumulation of cholesterol esters which leads to the formation of foam cells. Further accumulation of these cells by modified LDL leads to the formation of fatty streak which gets calcified to form atherosclerotic plaque. The features of atherosclerotic plaque include a lipid rich core with common focal calcification detected by the coronary calcium score, smooth muscle necrosis, neovascularisation and intra-plaque haemorrhage, vascular remodelling and luminal stenosis(39).

Signs and Symptoms

Chest pain that occurs regularly with activity, after eating, or at other predictable times is termed stable angina and is associated with narrowing of the arteries of the heart. Angina that changes in intensity, character or frequency is termed unstable. Unstable angina may precede myocardial infarction. In adults who go to the emergency department with an unclear cause of pain, about 30% have pain due to coronary artery disease. Cohort studies have shown an increased risk of cerebrovascular disease (stroke) in individuals with signs and symptoms of CAD compared with non affected individuals. Symptoms and signs of cerebrovascular

disease, particularly transient ischemic attack, carotid bruit, and completed stroke also identify individuals with a greater-than-normal likelihood of developing a coronary event(3).

Risk Factors

Coronary artery disease has a number of well determined risk factors. The most common risk factors include smoking, family history, hypertension, obesity, diabetes, lack of exercise, stress, and high blood lipids.Smoking is associated with about 36% of cases and obesity 20%.Lack of exercise has been linked to 7–12% of cases.Exposure to the herbicide Agent orange may increase risk.Both rheumatoid arthritis and systemic lupus erythematous are independent risk factors as well. A plethora of risk factors can predispose to IHD in women, ranging from Diabetes and Hypertension to Dyslipidemia to smoking and Obesity and the Stress of a multi-faceted and simultaneous multitasking personality, typical of a woman(41).

Some of the risk factors of CAD are mentioned below:

1)Cholesterol

2)Hypertension

3)Cigarette smoking

4)Family history

5) Diabetes mellitus where Diabetes imposes lifelong threats on the individuals and their families(40).

Discussion

CAD is a disease which is most common worldwide,with high mortality rate. This mortality rate depends upon the number of vessels involved. Various studiesreveal that single vessel disease has the lowest mortality rate, and triple vessel disease has the highest mortality

rate. Coronary heart disease is the leading cause of death in the US general population. With the obesity pandemic and the expected worsening of cardiovascular risk factors in the general population, the incidence and the prevalence of heart disease is expected to rise. Coronary artery disease (CAD) is the leading cause of death in patients with chronic kidney disease (CKD). Of the more than 320,000 patients with ESRD that requires dialysis or kidney transplantation in the United States, half will die from cardiovascular causes, and patients with milder degrees of CKD are more likely to die of CAD than to develop kidney failure that requires renal replacement therapy (20).

The incidence of coronary artery disease (CAD) is apparent from community surveys. The Bromley Coronary Registry is a contemporary community registry used to identify all symptomatic medical presentations of CAD in one population (21). All incident (first) presentations of exertional angina, acute coronary syndromes, and sudden cardiac death were recorded for the Bromley Health Authority in South East London (population 186 053, in men and women aged 25–74 years) for the period from 1996 to 1998. In the ARIC study in participants aged from 45 to 64 years, the average age-adjusted CAD incidence rates per 1000 person-years were 12.5 in white men and 10.6 in black men.(22)

According to AHA Heart Disease and Stroke statistics, it is estimated that 770 000 Americans had a new coronary attack in 2008, and 430 000 had a recurrent attack. It is estimated that 190 000 additional silent first acute myocardial infarctions (MIs) occur each year. Approximately every 26 s, an American will have a coronary event, and about every minute someone will die of one.(23)

There are marked variations in the epidemic of CAD among regions of the world, nations, and even between regions within a country (24).The age-standardized death rates from CAD are declining in many developed countries, but are increasing in developing and transitional countries, partly as a result of demographic changes, urbanization, and lifestyle changes. Nowadays ~3.8 million men and 3.4 million women worldwide die each year from CAD.(25) According to the Global Burden of Disease Study,(26) the developing countries contributed 3.5 million of the total number of 6.2 million deaths from CAD in 1990. The projections estimate that these countries will account for 7.8 million of the 11.1 million deaths due to CAD in 2020. According to global and regional projections of mortality and burden of disease, CAD will remain the leading cause of death for the next 20 years.(27)

In the USA and in most countries in the European Union, the age-standardized CAD mortality rates have decreased significantly. This may lead paradoxically to an increase in the prevalence of CAD; indeed a better survival of CAD patients and demographic changes result in more elderly people suffering from CAD. Today CAD is the most important major killer of both American men and women, causing approximately one of every five deaths in the USA in 2005.(28) Approximately 37% of the people who have a coronary event in a given year will die of it. In 2005 the overall CAD death rate was 144.4 per 100 000 population.

The death rates were 187.7 for white males and 213.9 for black males; for white females the rate was 110.0 and for black females 140.99. In the European Union, CAD is also the single most common cause of death. One in five to one in seven women die of CAD; in men CAD accounts for one in four to one in six of all deaths. Age-standardized and gender-specific CAD mortality rates have significantly decreased during recent decades in many countries in the north, west and south of Europe.

However, the decline was less apparent or absent in central and eastern Europe. Thus, the Russian Federation, Belarus, Ukraine, and Central Asian republics show the highest CAD mortality rates ever seen, significantly higher even than recognized peaks in the USA, Australia, New Zealand, Finland, and Scotland (29,30). Furthermore, population aging represents a major challenge. Thus, even if age-specific mortality rates continue to decline, the absolute number of cardiovascular disease (CVD) deaths will increase. Predictions up to 2030 suggest that even with an annual decline in mortality rates of about 1%, the absolute number of deaths will increase, attributable solely to population aging (27).

It has been estimated that 30–43% of patients who were asymptomatic after an MI had silent myocardial ischaemia in the initial 30-day period after the infarct, based on stress test data or Holter monitoring.(31,32). A recently published analysis in 937 outpatients with stable CAD from the Heart and Soul Study demonstrated that 14% of outpatients had angina alone, 20% had inducible ischaemia alone, and 4% had both angina and ischaemia. Recurrent CAD events occurred in 7% of participants without angina or inducible ischaemia, 10% of those with angina alone, 21% of those with inducible ischaemia alone, and 23% of those with both angina and inducible ischaemia.(33)

Coronary atherosclerosis most commonly presents in the community as angina pectoris, followed by acute coronary syndromes (MI and unstable angina), and finally as sudden

cardiac death. When the acute manifestations of CAD—sudden cardiac death and MI—are considered together, one in two patients with new or recurrent disease die within 30 days of their acute clinical presentation.(34-37) . About 69% die in the community, 29% die in hospital, and the other 2% die within 30 days of discharge. Congestive heart failure (CHF) is the result of the heart's inability to function effectively as a pump.(42)

The prognosis of patients with chronic CAD is not uniform. It depends on several factors, including the underlying coronary anatomy, left ventricular (LV) function, and comorbidities. The data concerning prognosis in clinical trials are of limited value due to the highly selective nature of populations included in such studies. Large population-based studies could help to increase our understanding of the differences in prognosis between CAD manifestations.

The recently published data on cardiovascular event rates from the REACH (Reduction of Atherothrombosis for Continued Health) registry in stable CAD outpatients (n = 38 602 patients) has confirmed that patients with established stable CAD had the highest non-fatal MI rate and the highest non-fatal stroke rate. The registry reported annual event rates of 15.2% for death, stroke, MI, or hospitalization for an atherothrombotic event, 6.4% for unstable angina, 4.5% for death, acute MI, and stroke, and 3.8% for revascularization by percutaneous coronary intervention (PCI).(38)

Thus, ~3 of 20 patients with established CAD had a major event or had been hospitalized within a year of follow-up. The high event rates observed in the subgroup of patients with established CAD in this large contemporary cohort indicate that continued efforts are needed to improve secondary prevention and clinical outcomes.

Our study reveals that out of 50 CAD patients 25 patients are affected with single vessel disease,, 9 patients are affected with double vessel disease,, and 16 patients are affected with triple vessel disease. The annual mortality rate of single vessel disease is less than 4%. The mortality rate of double vessel disease is 7-10%. The mortality rate of triple vessel disease is 10-12%.

The study results shows that diabetic and obesity amongst the young population as per the trend charts indicates the increase in the CAD. The chart represent the vessel blockage categorizing them in to single, double and triple where single blockage being a major one followed by triple. Gender wise, smokers and non-smokers among the male patients in

numbers and percentage are also represented through pie charts.

From the research study based on the clinical data provided it is evident that the current day life style poses a major threat to the young population being the victim of CAD. To emphasize for a healthy life, counselling on the life style, food habits, the need for exercises are to be carried out in preventing the young victims to CAD.

Conclusion

Cardiovascular diseases and CAD remain the leading cause of mortality in the world. In addition to the lifestyle and pharmacological approaches that are available to prevent and treat CAD, MI is emerging as a potential risk factor for CAD-related outcomes. Ongoing randomized trials are assessing the role of selective HR reduction in improving outcomes in patients with CVDs. Thus, preventing ourselves from such diseases rather than treating the deadly ones is much better and we have to join hands in abolishing such emerging deadly diseases in the future.

Abstract

Introduction: Stroke occurs when the supply of blood to the brain is either interrupted or reduced. When this happens, the brain does not get enough oxygen or nutrients which cause brain cells to die. High blood pressure is a risk factor for stroke recurrence. Mean Arterial pressure is a stronger predictor of cerebrovascular events than systolic or diastolic blood pressure. It is well known that patients with acute stroke, even without the history of previous hypertension, often have a very high blood pressure on arrival at the hospital. Mechanisms and effects of the BP elevation are unclear. On the other hand, high blood pressure may increase edema in areas surrounding a cerebral infarction or haemorrhage. In patients with acute stroke and very high BP, their blood pressure reduction should be gradual in order to preserve cerebral auto regulation to prevent further extension of the injury. So a study of 50 stroke patients and their blood pressure control is observed. The aim of the study is to assess whether hypertension is a risk factor of stroke.

Material and Method:50patients admitted with stroke in the medical wards in Saveetha Medical College from December 2015 till May 2016 was observed for hypertension.

Result: This study reveals that the signs and symptoms of stoke increases with the incidence of hypertension for that particular patient. Here, from the 50 stroke patients examined, 14 patients were reported with accelerated hypertension at the time of report, at Saveetha Medical College.

Conclusion:50 stroke patients were admitted with a complaint of dizziness and unconsciousness in the general ward at Saveetha Medical College have been diagnosed and treated with complete care. Out of which 14 patients have reported with accelerated hypertension at the time of report, which have no history of systemic hypertension. Maximum incidence of intra cerebral bleed was in above 60yrs. Females have highs systolic pressure compared to males which leads to increased intracerebral bleeding or hematoma. Under which their status were constantly monitored and maintained. From the above discussion it is clear that hypertension is a significant risk factor of stroke.

Introduction

Stroke is the third leading cause of death in the world. The incidence of stroke approximately doubles each decade after the age of 45, with a 2% annual risk over 80 years of age and a 3–7% annual risk over 95 years of age. It is the cause of one in eight deaths and constitutes a formidable burden of disability for the patients and their relatives and the wider community [1]. Stroke is defined as an abrupt onset of a neurological deficit that is attributable to a focal vascular cause and lasts more than 24 hours. It is manifested either, as brain infarction or haemorrhage. A variety of causes result in stroke which comes under two sub groups: One, resulting from ischemia and the other from brain haemorrhage. After thrombosis and embolism intracranial haemorrhage is the 3rd most frequent cause of stroke. Acute ischemic stroke, intracerebral hemorrhage and subarachnoid hemorrhage were the three main emergencies regarding stroke [1, 2]. However recent studies were stressing that untreated hypertension is a significant risk factor for hemorrhagic stroke [3, 4].

Materials and Methods

An observational study is carried out with duration of 6 months from December 2015 till May 2016. Fifty patients admitted with stroke in the medical wards, Saveetha Medical College were taken up for this study. A detailed history including symptoms, occupational history, address, history of diabetes mellitus, hypertension, ischaemic heart disease, cerebrovascular accident and family history of hypertension, diabetes mellitus, ischaemic heart disease, and cerebrovascular accident were taken from the conscious patients and from reliable care giver in unconscious patients. The patients had been subjected to detailed clinical examination including blood pressure, complete blood count, computed tomography scan were obtained in all subjects. Patient was constantly checked for blood pressure every 4 hours. Informed consent from the patients and approval from Ethics committee were also obtained.

Inclusion criteria: All stroke patients above the age of 35, with accelerated hypertension at the time of report and no history of systemic hypertension or under anti-hypertensive medications.

Exclusion criteria: All stroke patients below the age of 35 and history of hypertension and who are under anti-hypertensive medications

Results

The eldest stroke patient was 87 years old. Mean age of hypertensive bleed was 60 years. Of 50 stroke patients, 12 were females and 38 were males. 8 patients were Type II Diabetic, 14 patients have accelerated hypertension, 6 patients with the history of cerebrovascular events, 16 patients reported with hemeplegia. Of the 50 stroke patients examined, 14(28%) patients reported with accelerated hypertension at the time of report.

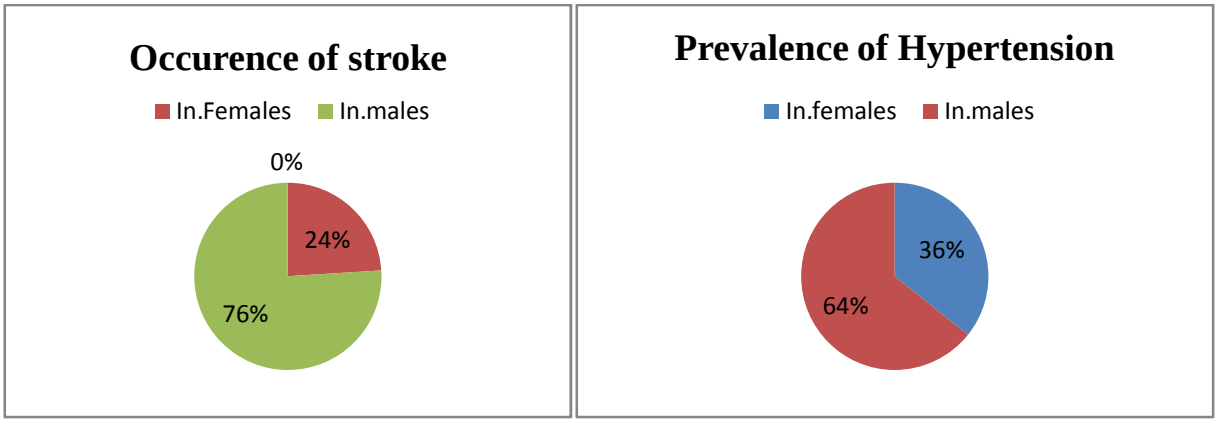

Figure 1 and 2: Shows prevalence of stroke and hypertension

Discussion

In this study, 28% of the patient has a history of hypertension regardless of the sex. CT brain scans of all the patients have been confirmed with stroke. On constant blood pressure check-up at every 4 hours, the initial blood pressure were greater than 190/140mmHg, the highest systolic pressure reaching 220mmHg and the diastolic pressure reaching 140mmHg recorded in a 47 year old female[8]. 47% of the female patients have a history of hypertension and an increased systolic blood pressure ranges between 220-190mmHg and also diastolic blood pressure ranges between 140-100mmHg. 40% of male patients has ischemic stroke. As the duration of hypertension increased the incidence of intra cerebral bleed also increased. High systolic and diastolic blood pressure is associated with increased risk of intra cerebral bleed. The incidence of intra cerebral bleed was found to increase stepwise with elevation of either systolic or diastolic blood pressure [5, 6]. Since the pressure inside the haematoma is equal to the arterial blood pressure, a high BP might be predisposing to large haematoma or re-bleeding. Hence patients with high blood pressure causes increased haematoma [7]. High blood pressure is evident in hypertensive patient; in such case 90%

of the female patients develop increased haematoma [9, 10]. Majority of the female patients with intra cerebral bleed had sedentary life style compared to males [11, 12]. Majority of the males were manual labourers. Even during the treatment hypertensive patients show varied blood pressures with took quite some time to stabilize them. Particularly in resource-limited settings, aside from BP control, stroke prevention efforts should be targeted towards these identified risk factors for stroke among hypertensive patients. Carotid diameter should be further explored as an intermediate risk marker for stroke [13-17].

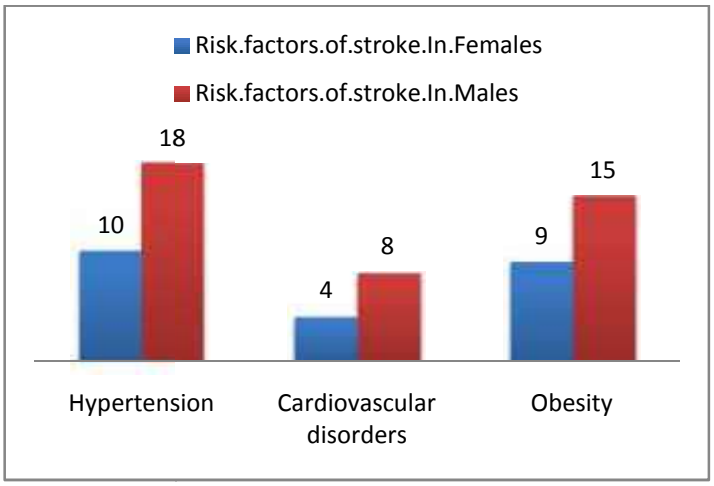

Figure 3: Graph showing percentage of risk factors among males and females

Conclusion

50 stroke patients were admitted in the general ward in Saveetha Medical College have been diagnosed and treated with complete care. Out of which 14 patients have reported with accelerated hypertension at the time of report, which have no history of systemic hypertension. Maximum incidence of intra cerebral bleed was in above 60yrs. Females have highs systolic pressure compared to males which leads to increased intracerebral bleeding or hematoma [18-20]. Under which their status were constantly monitored and maintained. From the above discussion it is clear that hypertension is a significant risk factor of stroke.

Abstract

Introduction: The smile plays an importantrole in facial expression. Facial attractiveness and smile aesthetics arestrongly related toeach other. An attractive, well-balanced smile is a highly regarded treatment objective, along with creating a functional occlusion. The aim is to assess the aesthetics by studying the influence of gingival exposure in the smile of patients.

Materials and Method: The study included 100 individuals. Colour photographofa smilingfemale changed on the computer,displaying thedifferent gingival exposures, from 5mm of gingival exposure to 5mm of upper lip incisor coverage was assessed by laypersons. The individuals were asked to rate the attractiveness of the smiles with altered gingival display. Statistics was done in SPSS software.

Results: 19% of laypersons have chosen 0mm as best smile which is no gingival exposure during smile .18% felt 1mm as best smile which is little amount of gingival exposure. 8% felt,-1mm as best smile which covers some portion of central incisors. 1% felt
-5mm as best smile.Age or gender didn't show any sort of variation.

Conclusion: The perception of laypersons in evaluating gingival display may be different from that of orthodontists.There is influence of gingival exposure in smile and thus contributing to aesthetics. Therefore, it is important for publicto participate inthe decision-making process of orthodontic treatment planning.

Key Words*: smile, gingival exposure,orthodontic treatment, attractiveness of smile, general public.*

Introduction

Smile is what gives beauty to a face. Everybody wants to have a beautiful smile as compliments, the personality, and appearance of a person. So however there is no definition for a beautiful smile. This is because the perception of a beautiful smile varies from person to person. What looks very good for somebody or even for the certain population may not be acceptable for people from different population or even within the same population. So this brings us to a very vital question on. Whether our perception of a good smile actually matches what they actually want.The smile is the most effective means by which people convey their emotions.[1].One smile can make all the difference in the world. One smile has the power to release stress, calm you down, make you attractive, make someone else happy and believe it or not, smiling can actually cause happiness. That is why; Smile at Life has become the personal motto for someday smile is the prettiest thing one can wear. This is absolutely true. Whether you are female or male, a smile is all you need to complete your beauty. There is nothing more attractive than a man with a smile. Besides, smiling also shows people that you are person with positive attitude and easier to get along with.Aesthetics is often the main complaint in the dental office and patients usually evaluate treatment results based on the positive changes in their smile.[2]. Each person has a particular way to self-assess his/her own appearance and the beauty of other persons. [3]. Physical attractiveness is an important social issue in our culture, and the face is one of its key features. [4].The demand for improved dental appearance is one of the major motives of orthodontic treatment.Aesthetic perception varies from person to person and is influenced by each person's experiences and social environment.The search for improved dent facialaesthetics persists in modern society. Thus, pretty faces and beautiful smiles were inspired and patients have sought treatment modalities to improve dent facialaesthetics' and so to the yieldpositive changes in their smile.[5-10].Once we realize the importance of the smile in a facial context, we are able to extrapolate even further. It is determining not only in the perception of facial attractiveness, but also with the perception of one's psychological characteristics.

Gummy smile has a negative effect on the aestheticsof smile. But we can correct the gummy smile easily through various treatment options. An overexposure of gum tissue in upper jaw can result from the abnormal eruption of the teeth. Teeth covered by gum tissue appear short, even though they might actually be the proper length.The manner in which the upper jaw bone grew and developed could cause the appearance of a gummy smile. For example, if

there was an excessive over protrusion of the upper jaw within the gum tissue, one might experience an obvious gummy appearance when they smile causing anaesthetic appearance. Smile analysis is the most important stage as far as diagnosis; treatment planning and treatment prognosis is concerned for any dental treatment involving aesthetics as their objective.

The evaluation of the intrinsic characteristics of the smile is a necessary procedure to achieve consistent form in orthodontic treatments, which in turn makes it necessary to recognise the components and factors that affect these characteristics. Evaluating beauty is always subjective. However, we need adequate tools to overcome the challenge of this subjectivity. In orthodontics, it is not enough only to recognize what is interfering with the smile—it requires a diagnosis of what is not normal, in order to establish a treatment plan.The smile line is the determining factor in the evaluation of mouth aesthetics. The aesthetic results of orthodontic treatments always maintain a strong relationship to smile line. It is not uncommon for the conclusion of orthodontic treatments to be compromised by the smile line. Either high or low smiles aid in compromising the results. This is the great challenge of contemporary orthodontics in its search for its excellence. This study is a attempt to solve this problem and to find out which type of smile is most liked by the patient. So the aim was to assess the aesthetics by studying the influence of gingival exposure in the smile of patients.

Materials and Methods

A set of smile photographs showing well aligned teeth were chosen. The teeth wereexposed at different levels in each picture. There were 11photos that were prepared for the study the teeth alignment were the same in all the pictures.The only difference in these pics was the amount of upper incisor crowns exposure below the lips. The exposure varied from -5 mm below the lip margin to +5mm above the gum margin. That is, The first smile had 5 millimetres of Gingival exposure below the central incisors , second smile picture had 4mm of gingival exposure, the third smile picture had the 3mm of gingival exposure, the fourth picture had to 2mm of gingival exposure, fifth picture had 1mm of gingival exposure ,Sixth picture had no gingival exposure ,Seventh picture had 5mm of only central incisor exposure Eight picture had only 4mm of central incisor exposure ,Ninth picture had only 3mm of central incisor exposure ,Tenth picture had only 2mm of central incisor exposure. Eleventhpicture had only 1mm of central incisor exposure, and the last picture had no central

incisor exposure. The pictures were randomly arranged and were shown to 100 general public. Among the 11 pictures displayed in front of them, the people engaged in the study were asked to select the best picture in their opinion and grade 1for the best smile and 5 being for the worst smile. The results obtained were statistical analysed and the conclusions were derived from the same.

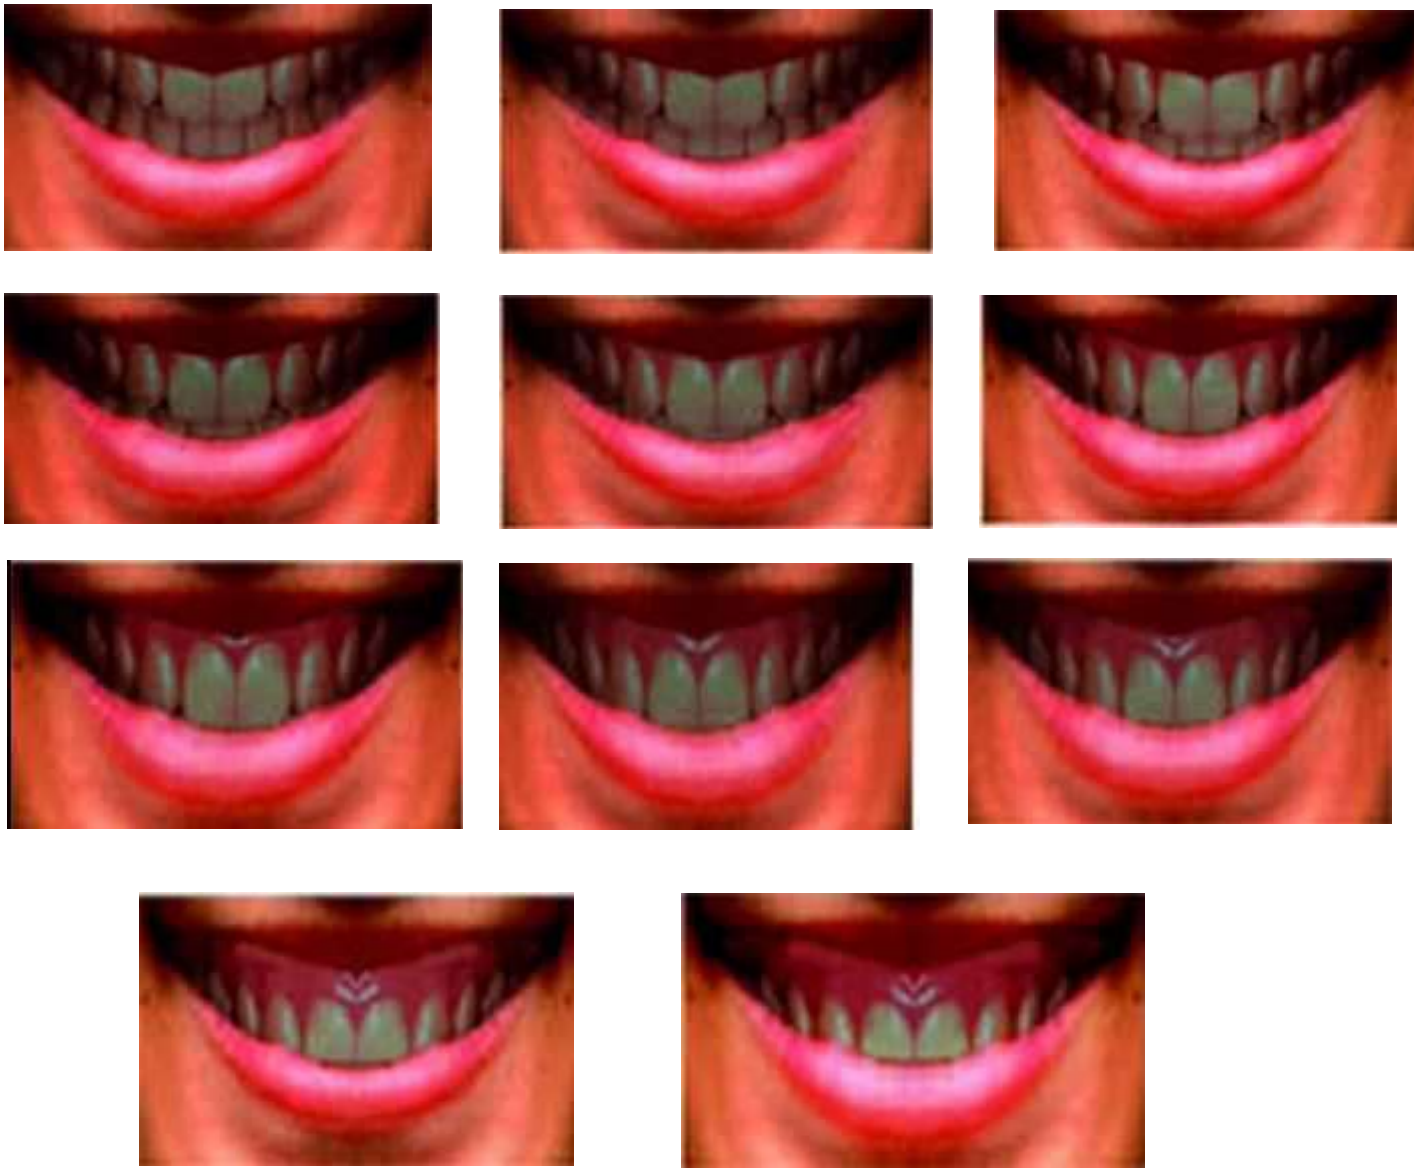

Figure: Photograph Showing Various Smiles with Gingival Exposure from -5mm To +5mm Respectively

Results

Among 200 individuals,19% felt 0mm as best smile which is no gingival exposure during smile. 18% feltt1mm as best smile which is little amount of gingival exposure was Seen. 13% felt 2mm as best smile in which gingival exposure was slightly increased compared to 1mm.12% felt 3mm as best smile which was slightly more exposure compared to 2mm.

11% felt 4mm as best smile which is more compared to 3mm and ,8% felt -1mm as best smile which covers some portion of central incisors. 7% felt -2mm as best smile which was covering more portion of central incisor compared to -1mm and ,5% felt -5mm as best smile,3% felt -3mm as best smile,3% felt -3mm as best smile,1% felt -5mm as best smile. And Age or gender didn't Show any sort of variation. (Table 1)(Fig1)

Table 1: FrequencyOf Gingival Exposures From -5mm To +5mm Influence On Smile Aesthetics

gingival exposure					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	-5.00	1	1.0	1.0	1.0

Discussion

The smile line or the aestheticzone is nothing but teeth which are when we smile is determined by various factors, including: The shape and size of lip, facial muscles, the shape and size of the teeth and the gum tissue. The optimal smile line appearance should reveal the least amount of gum tissue possible. Gum tissue which is visible in the smile line should b balanced, even that are in harmony with the upper lip. It is for this reason that many people with a gummy smile or excessive gingival display feel their smile to be unattractive, oftentimes feeling reluctant to smile at all. However, more serious underlying dental conditions could be present. The disproportionate amount of gum and tooth showing when you smile can be caused by the overactive muscles that control the top lip, which causes the lip to curl up and expose the excess gum tissue above the teeth. Showing ‘too much gum’ when smiling is often noticed when people look at photos of themselves.

A smile demonstrating minimal gingival display has been deemed to be more aesthetic than a smile with excessive gingival display. [11-13]The most important aesthetic goal in orthodontics is to achieve a balance smile which can be achieved by appropriate positioning of the teeth and gingival scaffold within the dynamic display zone. Smile develops when

person seeks happiness, humour or greetings. The amount of gingival display of the patients should be considered as an important parameter as far as aesthetics is concerned. Smile acts as a method of communication. The various etiological factors which have been described for an aesthetic smile is not only determined by tooth position, size, shape, and colour but also by the amount of gingival tissue revealed and the framing of lips [14]. Various conditions like malpositioning of teeth, altered passive eruption, recession, loss of inter proximal papilla leads to an anaestheticappearance. [15].Among the different involved factors, the aesthetics of the smile has an important influence in the perception about the individual appearance and personality [16, 17].

In some studies, post orthodontic treatment, there was different perception among different people. Kokich[18] reported that orthodontists classified smiles as least attractive only when midline shifts reached 4.0 mm. On the contrary, Pinho[19] reported that orthodontists and prosthodontists were less tolerant of dental midline shifts, and rated 1.0 mm and 3.0 mm shifts as less attractive, respectively. Ker [20] also found that laypersons accepted as much as 4 degrees of canting (equivalent to 3.0 mm).Our study as just focused on the best smile among the general public with no age or gender category. And gummy smile showed the least score and 0mm gingival exposure showed the maximum score.

Three important aspects are involved in analyzing smile aesthetics, such as, gingival display, curvature formed by the incisal edge of anterior superior teeth and the upper lip, and width of the buccal corridor [21]. From a strictly orthodontic perspective, dentogingival display and transverse dimension are usually considered the most important factors in smile analysisPreference is given to a smile line where the elevation of the upper lip is close to the gingival margin of maxillary incisors [22-26]. Most of the females were more concerned about their smiles, they were inspired by the patients already benefited by Orthodontic treatment and so they felt that they will look better after Orthodontictreatment [27]. In general the dentists were more critical than the patients as reported in other studies and more patients were satisfied with their appearance than were unsatisfied [28]. Position of lip during smile also influences the clinical and technical procedures required for aesthetic restorations.

Assessment of smile provides information about the relationship between the teeth and surrounding pink tissue, and is a key element of diagnosis and treatment planning in cosmetic

dentistry. The relationship between upper lip and display of gingival tissues and teeth denotesthat periodontal outlook depends on the smile architecture. An imaginary line following the lower margin of the upper lip, with a convex appearance is de Ned as smile line [29,30].

Dental attractiveness plays an important role in seeking orthodontic treatment.[31].Brisman's study [32]he segregated the opinions of patients, dental students and dentist, concluded that all groups preferred teeth of a similar shape, but the dentists preferred relatively longer and thinner teeth than the patients. Mehl (2015) showed a difference between students and dentists and emphasised the need to teach aesthetics at dental school [33]. Prahl-Andersen's study [34] compared the opinions of laypeople, general dentists and orthodontists, finding that the general dentists and orthodontists essentially agreed in their responses but as a combined group, they were much more critical than the laypeople that were more likely to accept increased or reverse overjets and mild crowding [34].Shiyan et al. (2016) stressed the need to be aware of the difference in perception between orthodontists and patient [35]. Others agreed and found orthodontists were found to be more critical than general dentists [36] [37]. Geographic variation in opinions also exists [38].

Conclusion

Gingival display of 0mm and 1mm showed highest score on our study. Knowledge about the intrinsic characteristics of the smile also helps in the aesthetic perception. Being able to evaluate the smile of each patient assures the professional of the possibility of seeing what needs to be done, what can be done, and what should be accepted. Which aids in interpreting the nuances of a smile gives each orthodontist the opportunity to act in a conscious manner in the mouth aesthetic treatment of their patients, allowing the diagnosis to be integrated with the prognosis and giving a realistic outlook of the results than can be obtained. Buccal corridor, number of exposed teeth during smiling, frontal, oblique and profile facial analyses, relationship between resting and speech positions and the smile are the factors that should also be observed in order to achieve a better diagnosis of mouth aesthetics. Theperception of laypersons in evaluating gingival display may be different from that of orthodontists. Importantly, treatment should be discussed with patients so as to individualize treatment planning and, as a result, fulfil their desires. Therefore, it isimportant for public to participate in the decision-making process of orthodontic treatment planning.

Abstract

Introduction: The third molar is the most commonly impacted tooth in the whole dentition because of the eruption timing and decrease in the length of Jaw .The mandibular third molars are the frequently impacted teeth in the human. They are often associated with pericoronitis, periodontitis, cystic lesions, neoplasm, pathologic root resorption and can cause detrimental effects on adjacent tooth. Also, many researches have shown that impacted third molar weakens the angle of mandible. It makes it susceptible to fracture and is implicated in the etiology of crowding of the lower arch. The various types of relationship of Inferior Alveolar Root canal to third Molar root tips are loss of roof of canal,Narrowing, Deflection, and dilaceration of roots.

Materials and Methods In this Observational study, up to 100 orthopantomograms (OPG) of the patients who were referred to the radiology clinics of the Saveetha Dental College were evaluated. Data including the gender, Pattern, the angulation type of mandibular third molar to second molar and its relation of third molar were evaluated by statistical tests.

ResultsOut of the 100 orthopantomograms, the most common type of impaction is the mesioangular(77%) and the least common type of impaction is distoangular. The winters classification was used for determining the type of impaction. The radiographis signs were assessed in this present study. The presence/absence of the four radiographic signs previously mentioned were examined and from the results it is seen that radiographic signs which can lead to nerve damage or associated with nerve damage are present in majority of the radiographs. The most common radiographic sign observed here is Narrowing/diversion of the nerve canal(46.1%) followed by interruption of lamina dura of the nerve canal(45.5%) and outline distortion/deviation of the canal.

Conclusion The absence of radiographic signs associated with a relationship between the LTM and the canal indicates a minimum risk of nerve damage. In this present study, only the presence/absence of the four radiographic signs previously mentioned were examined and from the results it is seen that radiographic signs which can lead to nerve damage or associated with nerve damage is present in majority of the radiographs.

Keywords : *Impaction, third molars, OPG's, angulation, nerve canals.*

Introduction

Tooth impaction is a pathological situation in which a tooth can not or will not erupt into its normal functioning position. This problem can be solved by dental treatment.[1] The removal of the impacted third molars can be simply performed using elevators and/or forceps, but may require surgical intervention. This increases the risk of complications, such as nerve paresthesia, alveolar osteitis, hemorrhage, or even fracture of the jaw.[2]Removal of mandibular impacted third molars are routine surgical procedure performed by maxillofacial surgeons in dental clinics as well as hospital setups. To prevent complications a useful diagnostic tool is needed that can determine the relationship between inferior alveolar nerve and the impacted third molar.Panoramic radiography is suggested as the technique of choice to evaluate impacted third molars as well as to estimate the pre-operative risk for inferior alveolar nerve injury associated with third molar surgery.[3] The mandibular third molars are the most frequently impacted teeth that can be found in human.[4] The prevalence of third molar impaction ranges from 16.7% to 68.6% [1] .Studies have shown that patients with retained impacted third molars are significantly more susceptible to mandibular angle fracture of the mandible,and is implicated in the etiology of lower arch crowding, Temporomandibular Joint (TMJ) disorders, vagueorofacial pain and neuralgias.[5,1]. Teeth which are impacted may cause detrimental effects on the adjacent tooth. They are most commonly associated withfactors like periodontitis, cystic lesions, neoplasm, pericoronitis, root resorption.[6] Patients with the impacted third molars may present with caries, pain, gingivitis and oral infections . [5] Various methods have been used for classification of

impaction, in which impaction is described based on the impaction level,[7] the angulations of the third molars,[8] and the relationship to the anterior border of the ramus of the mandible.

Various classifications have been given on impacted teeth such as Winters classification, Pell and Gregorys classification, Killey and Kay, Archers classification of impacted maxillary teeth, etc. Winter's classification is classified based on the inclination of the impacted tooth to the long axis of the second molar into distoangular, mesioangular, horizontal, vertical and transverse. This classification is used for the study as it is simple and easily understandable [9] Currently, the panoramic radiograph is the technique of choice to evaluate impacted mandibular third molars. It permits an initial evaluation of any problems related to impacted mandibular third molar.[2] The proximity of the lower third molar (LTM) to the inferior alveolar canal in the preoperative radiographic study is considered a risk factor for damage to the inferior alveolar nerve,the incidence of which is approximately 1.1%. [10]The reported frequency of inferior alveolar nerve injury associated with third molar removal ranges from 0.6% to 5.3% but the risk of permanent IAN injury is less than 1% . [3] Injuring the inferior alveolar nerve is rare but typical of specific surgical procedure. The patient’s age along with the experience of the surgeon and how deeply the tooth is impacted are influential factors.[11]

A radiographic examination is an imaging exam is an essential tool for diagnosis and surgical management. So accurate preoperative radiographic examination is therefore considered indispensable before extraction of mandibular third molar. It is one of the conventional diagnostic aids used in impactions. The ramus, distal bone covering the impacted tooth, relation of mandibular canal to the third molars, etc can be assessed.[12]

Thus, the objective of this study is to evaluate the pattern of third molar impaction and its relation to nerve canals using panoramic radiograph in a sample of hundred patients. The presence or absence signs which may cause damage to the canal were assessed in OPG'S (root contacting the nerve canal, narrowing/diversion of the canal, outline distortion, interruption of laminadura with the canal) in the study. The purpose of taking up this observational study is because of the paucity of literature and to throw a light upon the topic.

Materials and methods

Study Design An observational radiographic study.

This study was conducted on 100 patients. One hundred Orthopantomograms (OPG'S) of patients who presented to the outpatient Dental centre were selected for the study. Only the patients with the impacted third molars were included from the records.Third molar was considered impacted if it did not have any functional occlusion and at the same time roots were fully formed.

For the purpose of this study, OPG X-rays were selected randomly which meant that not all patients included in the study had attended the Clinic for the management of impacted wisdom teeth. The gender and the angulation of the lower impacted third molars were determined separately for the 3rd and the 4rth Quadrant from the OPG records and its relationship with the nerve canal is assessed by four questions – Q1)Whether the root contacting the nerve canal, Q2)narrowing/diversion of the canal, Q3) Outline distortion of the canal, Q4) Interruption of lamina dura. The radiographs were taken from the digital panaromic machine. The third molar was considered impacted when it was not fully erupted to the assumed normal functional position in the occlusal plane. The angulation of the impacted third molar was recorded using Winter's classifcation with reference to the angle formed between the intersected longitudinal axes of the second and third molars.

Study Area Saveetha Dental College, Chennai, Tamil Nadu.

Study Population Patients reporting to the radiology department of Saveetha Dental College.

Inclusion Criteria

The criteria for selection of radiographs are

- either unilateral or bilateral lower third molar impaction.
- Clinically asymptomatic or symptomatic patients

Exclusion Criteria

Records of patients aged younger than 17 years, records with any pathological dentoalveolar condition, any craniofacial anomaly or syndrome such as Down syndrome, cleidocranialdysostosis,with the presence of incomplete records and poor quality OPG, incomplete root formation of third molar, or absence of adjacent second molar, were excluded.

Results

The radiographic signs were evaluated using four questions

Q1) Whether the root contacting the nerve canal

Q2) Narrowing/diversion of the canal

Q3) Outline distortion of the canal

Q4) Interruption of lamina dura. The type of impaction was determined.

To compare proportions Chi-Square test is applied, if any expected cell frequency is less than five then Fisher's exact test is used. SPSS version 22.0 is used to analyse the data. Significance level is fixed as 5% ($\alpha = 0.05$). If P-Value is <0.05 then statistically significant.

A total of 100 panoramic radiographs of patients aged not younger than 17 years were examined. In this study, clinical data were collected from the only dental teaching hospital in Saveetha Dental College, which has a policy of using DPT for all new patients. It was seen that the younger years age group had the highest prevalence of tooth impaction but this decreased with increasing age. This may reflect increased dental awareness in this group of patients. However, the relatively high proportion of patients in their third decade may also have increased the overall prevalence of impacted teeth in this study. Of the 100 panoramic radiographs, mandibular third molars were most commonly encountered.The radiograph was analysed based on the angulations using winters classification. Table 1 shows questionwise distribution of the data based on the type of impaction. In this study, more than 50% of impacted mandibular third molars were mesially angulated (Graph 1).

Discussion

The position of the impacted lower third molars have been evaluated from the radiographs. The data were analysed using Pearson chi square test. The significance level is fixed as 5% ($p<0.05$).

In the present study, the most common angulation of impaction in the mandible was Mesioangular(77%) followed by horizontal (58%) and vertical(32%) .The present study is in agreement with those of Queket al,(13) Kramer and Williams,[14] and Moris and Jerman [15]Hemamalinibalaji et al,[3]MP Santosh kumar et al,[9]which says that the mesioangular impaction is the most common angulation in mandible. Linden et al., Hattab et al., Knutsson et al. and Sedaghatfar et al. in their study found maximum number of third molars to be mesioangular. [16,17,18,19]

However, the present study is in contrast to those of Hugoson and Kugelberg,[20] who found the vertical angulation to be the most common. This could be due to the fact that a different method of classification of angulation was used in this study.Hazza'a et al in their study also found highest number of vertically placed third molars followed by mesioangular, distoangular, and horizontal third molars. These variations in angulation of mandibular third molars may be because of the reason that the studied population in each study was quite different from each other.

It appears that mesioangular impactions are probably the commonest type and this may be due to their late development and maturation, path of eruption and lack of space in mandible at later age.[1]

It was mentioned above that the proximity of the mandibular third molar to the mandibular canal is considered a risk factor for damage to the inferior alveolar nerve.

In this present observational study, the third molar root was contacting the nerve canal in 50.2% of the cases. The most common radiographic sign observed here is Narrowing/diversion of the nerve canal(46.1%) followed by interruption of lamina dura of the nerve canal(45.5%) and outline distortion/deviation of the canal. This is in agreement with that of *Costa FWG et al* where the narrowing of the mandibular canal was present in 86 of the 126 studied cases (68.25%).[21] It also agrees withValmaseda-Castellón et al. [22], where diversion of the canal was the only radiographic sign statistically associated with nerve damage. For Blaeser et al. [23], darkening of the root, interruption in the white line of the canal and the diversion of the canal were all statistically related with nerve damage.

This study is also in agreement with that of Hemamalinibalaji et al[3] where the most significant radiological sign noticed was the diversion of the mandibular canal.In the literature review conducted by Leung and Cheung, [24] the incidence of IDN deficit was highest in lower wisdom teeth showing radiographic sign of diversion of ID canal by its root (30%), followed by darkening of root (11.6%) and defected root by the ID canal (4.6%).

For gaikwad PT et al,[25] the radiographic sign most consistently associated with nerve involvement was the interruption of white line of the canal (10%), followed by the diversion of the canal(5%). The presence/absence of risk factors observed in panoramic radiographs is not always accurate, since it is a bidimensional-imaging feature. For better observation of these signs is necessary to obtain an image in three dimensions, such as computed tomography, and thus enable a better and more accurate visualization of anatomical structures related to the third molar.

However, in the present study,only the presence/absence of the four radiographic signs previously mentioned were examined and from the results it is seen that radiographic signs which can lead to nerve damage or associated with nerve damage are present in majority of the radiographs/cases. For Sandhya et al[12]in their study, out of 100 cases of impacted teeth, 82 cases had radiographic findings associated with the impacted teeth.

It can be concluded that the absence of radiographic signs associated between the LTM and the canal indicates a minimum risk of nerve damage and viceversa.

Conclusion

Panaromic radiograph can be used as a valuable predictor of outcome of the impacted mandibular third molars position, as they have quite good cost-information ratio. In the

present study, the area of concentration was on the angulation of the lower third molars to second molars and its relation to nerve canals. Mesioangular type and horizontal type of impaction were observed most common and it should be taken into consideration for high frequency of complications after extraction. More precise studies are necessary to evaluate the impaction of third molars in a randomized sample representative of Indian population as they help to evaluate the pattern of third molars impaction in India. The radiographic signs in the OPG that indicate a relationship between the LTM and the inferior alveolar canal are considered a risk factor for nerve damage. The absence of radiographic signs associated with a relationship between the LTM and the canal indicates a minimum risk of nerve damage. In this present study, only the presence/absence of the four radiographic signs previously mentioned were examined and from the results it is seen that radiographic signs which can lead to nerve damage or associated with nerve damage is present in majority of the radiographs. The absence of radiographic signs associated with a relationship between the LTM and the canal indicates a minimum risk of nerve damage.

Further studies should also be conducted to determine how many patients with impacted third molars are symptomatic or actively seek treatment. Further studies are also needed to assess the pattern of third molar impaction in other regions. More precise studies are necessary to evaluate the impaction of third molars in a randomized sample representative of Indian population as they are required to evaluate the pattern of third molars impaction in India.

Abstract

Introduction: Complementary and alternative medicines such as tea tree oil have become increasingly popular in recent years. This essential oil has been used for several decades in European countries but have now become increasingly popular in a wide array of products. The primary uses of tea tree oil is mainly because of the antibacterial and antiseptic properties of the oil itself. Antibacterial activity of tea tree oil on clinical isolates of Escherichia coli has been reviewed in this study.

Materials and Methods: A total of 20 non repetitive urinary isolates of Escherichia coli were collected followed by qualitative method of Antibiotic Susceptibility testing.

Results: We have observed that, clinical isolates of E. coli were inhibited from 0.03-0.25% of tea tree oil. The MIC of tea tree oil was appeared to be 0.03% for E. coli

Conclusion: Tea tree is found to have antibacterial activity against clinical isolates of E. coli. However, the studies on toxic and irritant properties of essential oils are imperative, especially when considering any new products for human administration. This can be used as alternative and complementary antibacterial agents for controlling the infections.

Keywords: *Antibacterial, Escherichia, Antibiotic, Susceptibility, Infections*

Introduction

Escherichia coli, one of the most common and frequent etiological agents of urinary tract infection (UTI) and is also responsible for wide array of other infections such as bacteremia, pneumonia, soft-tissue infection and neonatal meningitis. Multiple antibiotic resistance exhibited by such E. coli strains is a major concern, as they are showing resistance even to the carbapenems, which are considered to be the last resort of antibiotics for such stubborn E. coli infections. Tea Tree Oil (TTO) or melaleuca oil is known since long for many of its medicinal uses and also for other uses [1]. It is an essential oil obtained from the leaves and terminal branches of M. alternifolia through steam distillation method. It is available all over the world and is used for its antimicrobial properties [2]. It should be handled with care as it is toxic on oral consumption and for injections but can be used for its topical application use [3] studies have shown that TTO is not genotoxic in vitro in mammalian cells [4]. It is incorporated as an active substance in many topical applications used for treatment of cutaneous infections for controlling dandruff, lice, herpes, acne and other skin infections [5]. After a study on Tea tree oil samples [6] about 100 compounds were identified in tea tree oil. Antibacterial activity of Tea tree oil has been noted and has been reported to be broad-spectrum inhibiting bacteria. The minimum inhibitory concentration (MIC) for tea tree oil for most of the susceptible bacteria has been reported ranging from 0.003% for Prevotellaintermedia [7,8] and maximum greater than 8% (v/v) for Enterococcus faecalis strains of bacteria [9]. A recent study on ATCC reference and clinical strains [10] of different bacteria namely, Pseudomonas aeruginosa ,Staphylococcus aureus, E. faecalis, Salmonella Enteritidis, S. Typhimurium and escherichia coli. Tea tree oil is bacteriostatic in low concentration but bactericidal at higher concentrations. Though exact mechanism of action is yet to be understood it is hypothesized and proved to some extent [11,12] that TTO act through increasing permeability of liposomal systems causing lysis and the loss of membrane integrity and manifested by the leakage of ions and the inhibition of respiration and ultimately death of the bacterium [13].In early studies on the antimicrobial activity of TTO, it was hypothesized to be more active against antibiotic-resistant bacteria [14] thus attracted considerable interest. Thereafter, several studies were conducted but only on a limited number of strains specifically using mupirocin resistant and methicillin-resistant strains of *Staphylococcus aureus* (MRSA) and of other bacteria [15,16,17]. Most of the studies concluded an insignificant

difference in TTO sensitivity of antibiotic-resistant and sensitive strains. Resistance to TTO in clinical isolates has not yet been reported and resistance of bacteria to conventional antibiotics has not been correlated with susceptibility to TTO, suggesting that cross resistance does not occur. Tea tree oil is seen as important alternative as a topical antimicrobial for antibiotics. Search for "alternatives to antibiotics" is identified as one of the most important goals to combat the emerging antibiotic resistant pathogens [18]. It is often claimed that TTO can replace antibiotics at least for topical applications [19]. The present study aimed to test the sensitivity of variety and number of the bacterial strain, isolated from clinical cases with the potential to cause a wound or cutaneous infections, to TTO and simultaneously to common use topical antimicrobials. Data, interpreted and was analyzed for contact and association between Tea tree oil sensitivity and antimicrobial sensitivity and multi-drug resistance in different bacteria different origins. Thus the aim of the study was to determine the antibacterial activity of tea tree oil against clinical isolates of E. coli.

Materials and Methods

Bacterial Isolates

A total of 20 non repetitive urinary isolates of Escherichia coli were collected from Saveetha Medical College and Hospitals, Chennai. They were processed for standard biochemical tests and confirmed. Isolates were preserved in semisolid trypticase soy broth stock and were stored at 4 ºC until further use. Antibiotic susceptibility testing was done.

Antibiotic Susceptibility Testing

Antibiotics/antimicrobial agents are the major drugs of choice of the physician's desk to treat the host of various infections. This prescribing pattern may be one of the reasons for the development of resistance for the antibiotics [20]. Therefore, Antibiotics susceptibility testing plays an important role to check the effectiveness and efficacy of a drug against a bacterial strain or several bacterial strains and select the best drug that acts against the strains. The main objectives of the testing are to find out drug resistance in common microorganisms and the susceptibility to drug of choice for a particular infectious

organism or bacterium can be found out and can be assured. Mechanism of antimicrobial resistance: There are number of ways by which microorganisms are resistant to antimicrobial agents. These includes: Bacteria produce enzymes which can destroy the antimicrobial agents before it reaches the targets e.g. Beta lactamase enzyme hydrolyses beta lactam drugs which develop resistance to it. Impermeable cell for antimicrobial drugs e.g. Gram negative bacteria may become resistant to Beta lactam antibiotics by developing a permeability barrier. Mutation develops macrolide resistance. Bacterial efflux pump that expels antimicrobial drugs from cell before they can reach their targets. Specific Metabolic pathways in the bacteria are genetically altered so that antibacterial agents cannot exert an effect [21,22]. Antimicrobial susceptibility testing has several important purposes which can include a) A laboratory test which can determine how effective antibiotic therapy is against a bacterial infection or infections b) Antibiotic Susceptibility testing can control the use of antibiotics in clinical practice. c) Antibiotic susceptibility testing will help the clinicians in choosing the choice of drugs for the treatment of infection or infections d) Antibiotic Susceptibility Testing can help the local sequence of antibiotic prescriptions. e) Antibiotic Susceptibility Testing can be used to reveal the changing trends in local isolates.

Methods of Antimicrobial Susceptibility Testing

There are several methods of antibiotic susceptibility testing. The method followed in this study was the qualitative method of Antibiotic Susceptibility testing.

Qualitative Method: This method is used for testing of isolates from healthy patients with an intact immune defense system, in less serious infections such as Urinary Tract Infection. There are two qualitative methods.

Disk diffusion test : The disk diffusion sensitivity test also known as the Kirby Bauer disk diffusion method. It is a simple and practical test which uses the antibiotic- impregnated wafers or disks to test whether particular bacteria is susceptible to specific antibiotic or not [23,24] The bacterial inoculum was uniformly spread using sterile cotton swab on a sterile Petridish Mueller Hinton agar. The antibiotic disks were placed on top of the previously inoculated Mueller Hinton agar medium surface with the help of sterile instruments like forceps. Each disc must press down on one another to ensure complete contact

with agar surface. The plates were incubated for 18–24 h at 35-37 degree C temperature in bacteriological incubator before an interpretation and arrival of the result. The antibiotic is found to diffuse from the disc into the agar in decreasing amounts, the further it is away from the disk. This states that the antibiotic that is furthest away from the disks has a better permeability in the disks. If the organisms were killed or inhibited by the concentration of the antibiotic, there will be no growth in the immediate area around the disks will be represented as the zone of growth inhibition. The diameter of the zone of inhibition is directly proportional to the sensibility of the isolate and to the diffusion rate of antibiotics through the agar medium. A zone of inhibition was measured in millimeters by either measuring the Radius: Measure half the distance of the zone and then multiply by 2. This method was used when part of the zone is not clear or has grown into another zone. Diameter: Measure the entire length of the zone and subtract the disk diameter . The standard disk size was found to be about 5 to 6 millimeters. The result of the test can be interpreted by using the criteria published by Clinical and Laboratory Standard Institute (CLSA formerly the National Committee for the Clinical Laboratory Standard or NCCLS) [25]. The results of the disk diffusion test are “qualitative” and will be reported out as: Susceptible: ‘The term “susceptible” represent that isolates are inhibited by the usually recommended dosage of an antimicrobial agents. However, this term doesn’t fully assure clinical success in all cases. Predicting clinical outcome based on susceptibility testing and the use of drugs shown to be in the susceptible category is very imprecise. This imprecision is due to the effect of host responses, site of infection, toxin production by bacteria that is independent of antimicrobial susceptibility, the presence of biofilm, drug pharmacodynamics and other factors. As an outcome, there can be two categories, namely Intermediate and resistant categories.

A. **Intermediate:** ‘The “intermediate” category includes isolates with antimicrobial MICs that approach usually attainable blood and tissue levels and for which response rates might be lower than for other susceptible isolates. The intermediate category implies clinical efficacy in body sites where the drugs are physiologically concentrated, quinolones or beta lactams in the urine or when a higher than normal dosage of a drug can be used (e.g. Beta lactams).

B. **Resistant:** 'The category indicates that the isolates are not inhibited or stopped by the usually achievable concentrations of the antibiotics with normal dosage schedules, which demonstrate an existence of the specific microbial resistance mechanisms (e.g. Beta lactamase). The merits of the disk diffusion methods are simplicity in test, most patient cost friendly, a wide variety of disks can be chosen during disk selection, and the result can be easily interpreted by the clinicians. However, the demerits of this can include manual test, lack of automation and all slow growing bacteria cannot be accurately tested by this method. The limitation of this testing show that the microbiologist and clinician both should be cautious and should not forget that the response therapy in vivo may not always reflect the result of testing the sensitivity of patient's pathogen in vitro. A study conducted by Rakesh Kumar to study antimicrobial sensitivity pattern of Escherichia coli from urine samples of UTI patients used the resistant test method [26].

Well diffusion method: In this agar well diffusion method, a suitable agar medium was prepared, once the agar is solidified the medium was fully inoculated and was swabbed with bacterial suspension of approximately 1-2 X 108 CFU/mL using a cotton swab. The wells were prepared by punching with a six millimeters diameter standard sterile cork borer made up of stainless steel . These wells were filled up with 25 – 50 µL of the antimicrobial solution/s to be tested. Well diffusion test has been used for susceptibility testing of antifungals like fluconazole, itraconazole. The plates were incubated at 35 ± 2°C for 18 – 24 h. The antimicrobial activity is calculated in millimeter by using the expression: ZOI = Total Diameter of growth inhibited zone minus diameter of the well, where, ZOI is Zone of inhibition. The factors which may affect the result of AST included Density of an inoculum, Disk application time, Temperature of incubation, Potency of drug, inappropriate storage conditions, pH the agar medium, Moisture on the surface of the medium and effects of Thymidine or Thymine containing agar medium [20]

Results:

Sample wise distribution of clinical isolates of E.coli:

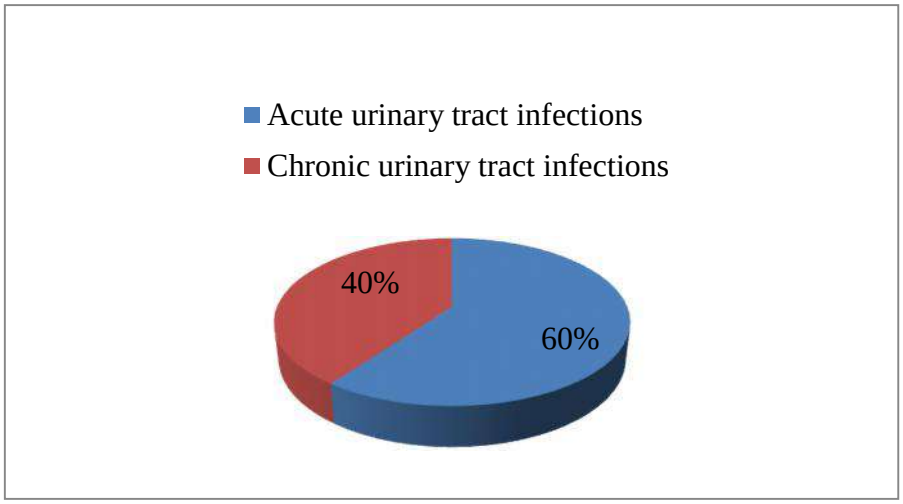

Figure 1: Sample wise distribution of urinary isolates of *E.coli*

Antibiotic Susceptibility Testing

Table 1: Antibiotic sensitivity pattern of E.coli

Antibiotics	Sensitivity(20) (%)	Intermediate (20) (%)	Resistant(20) (%)
Ampicillin	5	0	95
Amoxicillin	5	0	95
Ceftazidime	10	10	80
Cefotaxime	5	5	90
Amikacin	70	10	20
Gentamicin	45	20	35
Norfloxacin	15	15	70
Ciprofloxacin	20	5	75
Imipenem	70	0	30

We have observed that, clinical isolates of E. coli were inhibited from 0.03-0.25% of tea tree oil.

The MIC of tea tree oil was appeared to be 0.03% for E. coli.

Table 2: MIC of Tea Tree Oil

Dilutions of Tea tree oil	0.03%	0.06%	0.125%	0.25%	0.5%	1%	2%
No. of organisms	4 (20)	2 (10)	6 (30)	8 (40)	0	0	0

Discussion

Antibiotic susceptibility test fixed to routinely used antibiotics such as ampicillin, amoxicillin, norfloxacin, ceftazimide, cefotaxime, ciprofloxacin and gentamicin, imipenem by the Kirby Bauer disc diffusion method. Complementary and alternative medicines such as tea tree oil have become increasingly popular in recent decades. This essential oil has been used for almost 100 years in Australia but is now available worldwide both as neat oil and as an active component in an array of products. Tea tree oil have been historically used for their antiseptic and antiinflammatory actions. Food processors, food safety researchers, and regulatory agencies have been increasingly concerned with the growing number of food borne illness outbreaks caused by some pathogens. The increasing antibiotic resistance of some pathogens that are associated with foodborne illness is another concern. Hence, there has been increasing interest in the development of new types of effective and nontoxic antimicrobial compounds. Plant essential oils are a potentially useful source of antimicrobial compounds. Although numerous studies have been published on the antimicrobial activities of plant compounds against many different types of microbes, including food borne pathogens a review of the earlier literature reveals that the results reported for these different studies are difficult to compare, presumably because of the different test methods, bacterial strains, and sources of antimicrobial samples used.

Detection of antibacterial activity of tea tree oil against clinical isolates of E. coli:

Anti-bacterial activity of tea tree oil was tested against E. coli isolates by minimum inhibitory concentration method.

Mueller Hinton broth was supplemented with 0.002% (V/V) tween 80 (HiMedia, Mumbai) to enhance the dispersion of the essential oil. Agar dilution method was performed to attain the different concentrations of essential oil such as 0.03%, 0.06%, 0.125%, 0.25%, 0.5%, 1% and 2% in Mueller Hinton Agar (MHA). Media containing various concentrations of essential oil were poured over the sterile petridishes and allowed to dry. Media without essential oil was served as control plate.

Spot inoculation of 0.5 McFarland standard turbidity adjusted isolates were made on the plates and incubated at 37ºC for overnight.

The lowest concentration of the essential oils that completely inhibited the growth of isolates was considered as MIC. The lowest concentration of the essential oil, here tea tree oil that completely inhibited the growth of the isolates of Escherichia coli was found to be about 0.03 % in this study. This is found to be a much lower MIC when compared to the MIC achieved by other plant essential oils in a similar study which covers a whole spectrum of antibiotics. The MIC achieved in this study conducted in Australia was found to be about 0.23%.[21]. Another study performed confirms that many essential oil plant extracts possess in-vitro antibacterial and antifungal properties. The MIC as per this study was found to be roughly the same as in our study.[22] Another study, aimed at studying the membrane integrity of e coli bacteria when exposed to several different antibiotics upon tea tree oil, found that e coli lost its surface cell membrane integrity when it was exposed to around 0.5 % MIC of the antibiotic. [23]

Conclusion

Tea tree is found to have antibacterial activity against clinical isolates of E. coli. Nevertheless, the studies on toxic and irritant properties of essential oils are imperative, especially when considering any new products for human administration. This can be used as alternative and complementary antibacterial agents for controlling the infections.

Abstract

Introduction: The use of essential oils from herbs and spices is a novel antimicrobial treatment to reduce the initial microorganism loads. In herbs and spices, there are many antimicrobial compounds exhibiting a wide range of activities against bacteria, yeasts and fungi. Essential oils from plants have been suggested as natural preservatives.Thus the aim of the present study is to assess the antifungal activity of ginger oil against clinical isolates of candida species.

MaterialsandMethods:A total of 20 non-repetitive clinical isolates of Candida species were collected from different samples of immunocompromised individuals attending a medical hospital, in Chennai. They were characterized by carbohydrate fermentation and assimilation tests and confirmed. Isolates were preserved in semisolid Sabouraud chloramphenicol semi solid stock and stored at 4˚C until further use. Candida species were further characterized by using Hichrom agar (Himedia, Mumbai).

Results: Clinical isolates of Candida sp. were inhibited from 0.125-1% of ginger oil. The MIC of ginger oil was appeared to be 0.25% for Candida spp**.**

Conclusion: The ginger oil is found to have antifungal activity against Candida spp. Since, any toxic or irritant property of ginger oil has to be under consideration, ginger oil can be used as alternative and complementary agent for controlling fungal infections.

Key Words: *Ginger oil, Candida species, Antifungal, Sabouraud agar, chloramphenicol, Medicinal plants, Cytoprotective*

Introduction

Medicinal plants are used as pharmaceuticals, nutraceuticals, cosmetics and also food supplements [1]. Plant derived products have been used for medicinal purposes for centuries. In traditional Indian medicine or Ayurveda, Zingiber officinale and many other herbs have been used as medicine. One of the most common infectious diseases of humans is urinary tract infections (UTIs), caused by Candida species, which responsible for more than 80% of cases worldwide. [2] About 6 to 20% of the human populations are experiencing asymptomatic bacteriuria (ABU), depending on age and gender and nearly 50% of women suffer from cystitis in their lifetime. Many ABU Candida isolates are phylogenetically associated to virulent uropathogenic Candida (UPEC) strains and some may have evolved from pathogenic strains by virulence attenuation. [3]Epidemiological studies also revealed rise in local fungal infections of chronic wounds (diabetic foot, burn, bed- sore, cancer ulceration), with the involvement of C. albicans biofilm.In the past two decades increased prevalence of fungal infections has been reported. Fungi cause both superficial and internal mycoses. Systemic fungal infections constitute a major community health problem in many parts of the world, both in developed and developing countries. Along with other potential infections, candida affecting oral environment is become common leading to oral thrush, denture stomatitis. Candida species are capable of causing a variety of deep seated and superficial infections. Candida sp are considered as one of the most hospital acquired infection. Due to increase in multi-drug-resistant strains of Candida, it is become necessary to search for new sources of antifungal agents and compounds that inhibit these resistance mechanisms. This has led to a search for therapeutic alternatives, particularly among medicinal plants and compounds isolated from them used for their empirical antifungal properties. The in vitro antimicrobial evaluation of lozenges containing extract of garlic and ginger was carried out. Results indicated that there was inhibition of growth by nystatin tablet but garlic and ginger combination only inhibited growth of laboratory strains of C. albicans.The use of essential oils from herbs and spices is a novel antimicrobial treatment to reduce the initial microorganism loads. In herbs and spices, there are many antimicrobial compounds exhibiting a wide range of activity [4].Hence, there is a great demand for novel antifungals belonging to a wide range of structural classes, selectively acting on new targets with fewer side effects. One approach might be the testing of plants traditionally used for their antifungal activities as potential sources for drug development. Medicinal plants are not only important to the millions of people for whom traditional medicine is the only

opportunity for health care and to those who use plants for various purposes in their daily lives, but also as a source of new pharmaceuticals.[5]

Ginger is an important spice in Thailand. In 2001, Thailand grew more than 30,000 million tons of ginger. It is widely used as an ingredient in the food, pharmaceutical, cosmetic and other industries. Garlic and ginger have been known to possess immunological and cytoprotective effects in the biological host. Ginger contains a unique flavour derived from both non-volatile and volatile oils. The pungent compounds are gingerol and shagaol, while zingiberene is a pre-dominant component of oils. Some volatile compounds having antimicrobial properties present in gingerare α-pinene, borneol, camphene and linalool.[6]The medicinal properties have been mainly used for treating the symptoms of vomiting, diarrhea, light-headedness, blurred vision, dyspepsia, tremors, decrease in body temperature and high blood pressure. Furthermore, 6-gingerol and 6-shagaol can reduce viability of gastric cancer cells.[7].[8] Ginger extracts have been reported to inhibit growth of Listeria monocytogenes, Salmonella typhimurium, Staphylococcus aureus, Bacillus cereus, B. subtilis, F. moniliforme and Mycobacterium sp.[9] The garlic and ginger lozenge demonstrated pronounced antifungal activity against the laboratory isolate of C. albicans but not against the clinical isolates of the same organism while nystatin gave inhibition zone diameter values of 21 to 41 mm. Escherichia coli and Staphylococcus aureus strains were resistant. Ginger oils showed very good inhibition of Salinococcus roceus, H. turkmenicus and Halococcus morrhuae isolated from salt cured fish.[10] Thus, the present study indented to determine the antibacterial activity of ginger oil against clinical isolates of Candida sp.

Materials and Methods

Candida Isolates

A total of 20 non-repetitive clinical isolates of Candida species were collected from different samples of immunocompromised individuals attending a medical college, in Chennai. They were characterized by carbohydrate fermentation and assimilation tests and confirmed. Isolates were preserved in semisolid Sabouraud’s chloramphenicol semi solid stock and stored at 4˚C until further use.

Characterization of Candida Species

Candida species were further characterized by using Hichrome agar (Himedia, Mumbai).

Preparation of Hichrome Agar

CHROM agar Candida (HiMedia, Mumbai) was prepared following manufacturer's instructions. About 21.02 gram of HiChromeCandida differentiation agar base (modified) was suspended in 500 ml of distilled water. It was heated to boiling gently to dissolve the medium completely. Then it was allowed to cool to 50^{o}C and rehydrated (one vial) contents of HichromeCandida selective supplement was added under aseptic precautions. It was mixed well and poured into petri dishes. Isolates were identified on Hichrome agar based upon the characteristic colour of the colony by sub culturing from Sabouraud's chloramphenicol agar plates and the Candida Hichrome plates were incubated at 37oC for 24- 48 hours. [8] Based on colour produced by the isolates speciation have been made.

Table 1: Isolated Candida Species

***Candida* species**	**Color**
C.albicans	Green
C.tropicalis	Blue
C.krusei	Pink dry colonies
C.kefyr	Pale
C.parapsilosis	Pale

Detection of Antifungal Activity of Ginger Oil against Clinical Isolates of Candida Spp

Antifungal activity of ginger oil was tested against Candida isolates by minimum inhibitory concentration method. Mueller Hinton broth was supplemented with 0.002% (V/V) tween 80 (HiMedia, Mumbai) to enhance the dispersion of the essential oil. Agar dilution method was performed to attain the different concentrations of essential oils such as 0.03%, 0.06%, 0.125%, 0.25%, 0.5%, 1% and 2% in Mueller Hinton Agar (MHA).

Viability controls were performed on the fungal strains in the liquid medium under the same assay conditions. The plates were sealed and incubated at 35°C ± 2°C for 24 to 48 h. The MICs of the products used in the biological assays were defined as the lowest concentrations capable of visually inhibiting the fungal growth in the wells, as compared to the growth under control conditions

Media containing various concentrations of essential oils were poured over the sterile petridishes and allowed to dry. Media without essential oil was served as control plate. Spot

inoculation of 0.5 McFarland standard turbidity adjusted isolates were made on the plates and incubated at 37ºC for overnight. The lowest concentration of the essential oils that completely inhibited the growth of isolates was considered as MIC. [11]

Results

Characterization of Candida Species by HichromeCandida Agar

A total of 20 clinical isolates of Candida sp were seeded on to Hichrome Candida agar and results were tabulated based on pigment production.

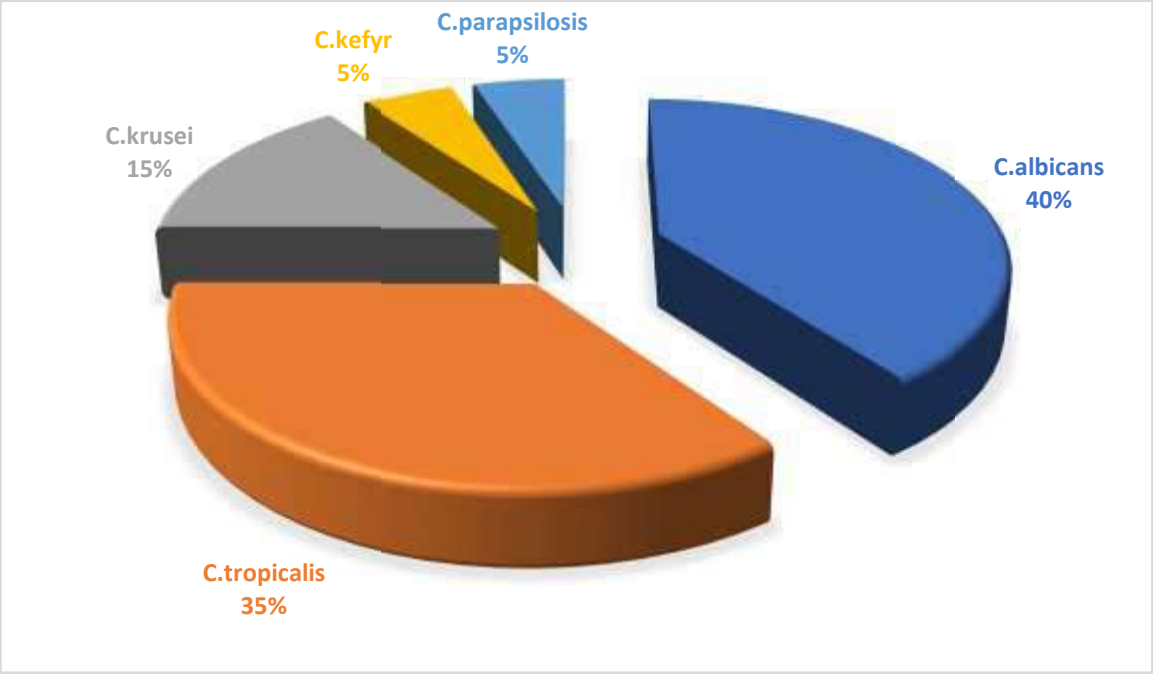

Figure 1: Pie chart showing distribution of Candida species

Figure 2: Representative picture showing Candida species on Hichrome Candida agar

Sample wise Distribution of Candida Species

Of the 20 clinical isolates of Candida sp, 6/20 (30%) were from oral thrush, 5/20 (25%) from urine, 3/20 (15%) from sputum, 3/20 (15%) from vaginal swab, 2/20 (10%) from ear swab and one (5%) from wound swab.

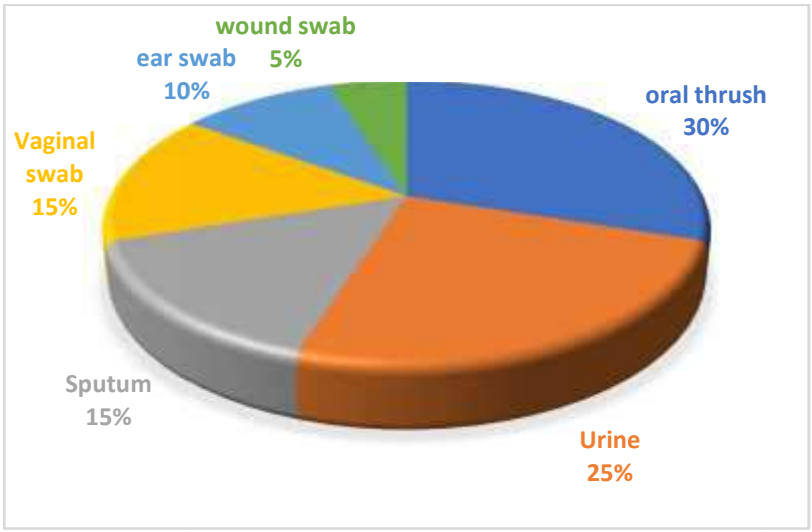

Figure 3: Result of antifungal activity of ginger oil against clinical isolates of Candida species

We have observed that, clinical isolates of Candida sp were inhibited from 0.125-1% of ginger oil.

The MIC of ginger oil was appeared to be 0.25% for Candida spp**.**

Table 2: The MIC of ginger oil against isolated Candida Species

No. of organisms	0	0	3 (15)	2 (10)	9 (45)	6 (30)	0

Discussion

Plant oils used as cooking and flavouring agents are increasingly claimed to have broad spectrum antimicrobial activity. Selected oils have been suggested to have potent antimicrobial activity against skin infections, insect bites, chicken pox, colds, flu, measles, sinus congestion, asthma, bronchitis, pneumonia, tuberculosis and cholera, probably due to their phenolic, alcoholic and terpenoid constituents.

The various therapeutic effects of ginger has been reported which includes anti-emetic activity, anti- ulcer, antiplatelet, antipyretic, anti-inflammatory and antioxidant activity[11]. The antifungal activity of ginger has been attributed to gingerol and shagelol derived from the ethanolic extracts of ginger [12]

The study results are comparable with other studies suggesting that different antifungal agents are present in the Ginger extract. In the ginger rhizome there are several components which have antibacterial and anti-fungal effects.(13] The study done by Supreetha.S on antifungal therapy has shown that ethanol itself has antifungal activity against candida albicans. However, there was an increased inhibition zone when ethanolic extract of ginger was used when compared to ethanol alone and this was statistically significant.(14)

According to the study by Anupama N. Devkatte Gajanan B. Zore S. Mohan Karuppayil, these oils required more than 1.0% to exert fungicidal effect. MFC of these oils ranged from 1.0% to 3% except in the case of Jasmine, Ginger and Juniper oil, which were not fungicidal up to the 3% concentration.[15]

The higher content of geranial and other oxygenated compounds makes fresh ginger oil more potent than dry ginger oil. The content of hydrocarbon compounds are more in dry ginger oil compared to fresh ginger oil. [16] Earlier studies have reported that monoterpene compounds are more active than sesquiterpene compounds. Dry ginger oil hadhigher content of sesquiterpene hydrocarbons.Especially when this is compared to the results obtained for the standard nystatin tablet where the C. albicans strains showed susceptibility. It is worthy to note that in most cases of infection, a combination of antimicrobial activity and

one or more other biological effects, such as immunomodulation, could be responsible for overall effect of a natural product [17]

Study conducted by Prakasam et al from Chennai in 2014 demonstrated that, Acinetobacter strains were inhibited from 0.06 to 0.25%, 0.25-1% and 0.125-1% for clove, peppermint and eucalyptus oils respectively. In clove oil, 14/50 (28%) isolates were inhibited at 0.06%, 25/50 (50%) at 0.125% and 11/50 (22%) at 0.25% of clove oil. In peppermint oil, 34/50 (68%) isolates were inhibited at 0.25%, 12/50 (24%) and 4/50 (8%) were at 0.5% and 1% concentrations of peppermint oil respectively. In eucalyptus oils, 10/50 (20%) isolates were inhibited at 0.125%, 18/50 (36%) at 0.25%, 16/50 (32%) and 6/50 (12%) were at 0.5% and 1% respectively. Thus, the MIC of clove oil was found to be 0.06%, 0.25% for peppermint oil and 0.125% for eucalyptus oil. [19,18] In contrast, in our study, we used ginger oil against Candida sp isolates. 15% of isolates were inhibited at 0.125%, 10% were at 0.25%, 45% were at 0.5% and 30% were at 1% of essential oil.

Thus, the MIC of ginger oil against Candida sp was found to be 0.125%.The resistance of clinical strains of C. albicans isolated from prosthesis users to the antifungal standard nystatin, which is used for the treatment of Candida-associated denture stomatitis, demonstrates the importance of investigating the efficacy and mode of action of novel products on this clinically relevant pathogen. Such research will facilitate the discovery of new antifungal agents. [20]

In some essential oils such as eucalyptus and clove oils, there has been much research and documented some toxic and irritant properties. In spite of this, most of these oils are available as whole oils or as part of pharmaceutical and cosmetic products. However, the studies on toxic and irritant properties of essential oils are imperative, especially when considering any new products for human administration.[21]

The addition of citral to the growth medium at a sub-inhibitory concentration of 4 µg/mL (MIC/8) did not alter the resistance of the clinical strains or the standard to nystatin, as assessed by proliferation. Furthermore, there are no studies in the literature investigating the ability of citral to modulate nystatin activity. The ability of unconventional compounds to increase the antimicrobial activity or reverse the resistance of microorganisms to drugs classifies the compounds as modifiers of antifungal activity [22].

It is therefore likely that a combination of these biological effects of garlic and ginger and the demonstrated antimicrobial effect may explain its usefulness in the management of oropharyngeal infections, especially those of fungal origin in folklore medicine.

Conclusion

The ginger oil is found to have antifungal activity against Candida spp. However, the studies on toxic and irritant properties of essential oils are imperative, especially when considering any new products for human administration. This can be used as alternative and complementary agent for controlling the infections.Nowadays, the indiscriminate use of commercial antimicrobial drugs has caused multiple drug resistance in human pathogenic microorganisms. The resistance strains of C. albicans have become a cause of major health concerns and require novel antifungal agents to tackle this problem.

Abstract

Introduction: Teeth are the structures which are highly resistant to higher temperatures, fragmentation and destruction. These characters make it possible to be used in various forensic and anthropological studies. In this study we use the mesiobuccal-distolingual (MBDL) and distobuccal-mesiolingual (DBML) crown diameters of maxillary canine and maxillary molar teeth on the study models measured using digital Vernier calipers.

Aim and objective: To study degree of sexual dimorphism in teeth of using crown diagonal diameters.

Materials and Method: Mesiobuccal-distolingual (MBDL) and distobuccal-mesiolingual (DBML) measurements of the crown and cervix of maxillary canine and maxillary molar were taken using digital vernier callipers in 120 upper dental casts obtained from 60 males and 60 females of the age group of 17-30 years.

Results: The stepwise discriminant functional analysis showed percentageof sexual dimorphism maximum for left canine crown MBDL, right canine crown MBDL and left canine crown DBML. Accuracy rate of gender determination is 68.3% in males and 65.0% in females.

Conclusion: Sex identification of a person with teeth remains is an inexpensive and easy method which is useful in forensic odontology. Diagonal measurements are preferred over linear measurements in case of attrition, crowding, malposition of teeth.

Key Words: *Sexual dimorphism, Diagonal measurements, Canine, Molar, Forensic odontology*

Introduction

Identification of sex of unrecognised skeletons is an important step in building the biological profile in forensics which helps in establishing identity of the individual [1] and one of the oldest approaches in forensic anthropology and medico-legal examinations [2]. Sexual dimorphism refers to a group of characteristics that differentiate male and female[3]. These are the differences in size, stature and appearance between male and female that can be applied to dental identification because no two mouths are alike[4].In massive disasters, even when other structures of body are destroyed, teeth are most often preserved[5].The unique pattern of tooth enables antemortem and postmortem analysis of dental variables.They provide higher degree of resistance to damage such as bacterial decomposition, fracture, fire etc. [6]

They are used in genetic, anthropological, forensic and odontologicalinvestigations as they are the hardest and chemically stable tissue in the body[7,8].

Tooth size has been evaluated in various populations in forensic and anthropological applications[3]. They show some differences in sexes and population[9] and is determined by cultural, environmental, genetic and racial factors[10].

Traditionally gender determination using tooth dimensions are determined using mesiodistal and buccolingual crown diameters of teeth. These dimensions get affected by attrition, cervical abrasion, crowding and presence of dental calculus in cervical third[11,12].As a result alternative dental measurements were developed to overcome these problems. Hilson et al., proposed diagonal diameters Mesiobuccal-distolingual crown diameter, Mesiolingual-distobuccal crown diameter, Mesiobuccal-distolingual cervical diameter and Mesiolingual-distobuccalcervical dimeters[13].

In this study diagonal measurements of maxillary canines and first molars are used. Canines are least affected than any other teeth by periodontal disease and are last teeth to be extracted. They have been found to be recovered from hurricanes and air disasters and withstand extreme conditions[14].

Molars are the first teeth to erupt in oral cavity. Hence they are available for sex assessment at an early age when compared to other permanent teeth[15].

The aim of this study is to determine the degree of sexual dimorphism using upper canines and first molars using diagonal measurements.

Materials and Methods

Study samples included 120 upper dental casts obtainedafter informed consent from 60 males and 60 females of the age group of 17-30 years in Chennai population.

Selection criteria: It included fully erupted right and left permanent maxillary canine and first molar, healthy state of periodontium, caries free teeth and with no history of orthodontic treatment. Any fillings, extractions, crowns, orthodontic anomalies that could affect the odontometric measurements were excluded from the study.

After taking informed consent, alginate (irreversible hydrocolloid) impressionsof the upper and lower jaws were taken followed by immediate preparation of their models with dental stone to prevent dimensional change.

Using the casts, Mesiobuccal-distolingual and Distobuccal-mesiolingual measurements were taken in dental casts using digital Vernier calliper of 0.01mm resolution.

Two crown and two cervical diagonal measurements of upper canine and first molar of right and left sides were taken. Each dimension was measured twice at different time interval by the same observer. After placing the calliper parallel to the occlusal surface, the following points were taken as guide during measurements[13,16].

Mesiobuccal-distolingual crown diameter: Defined as maximum distance from the mesiobuccal corner of the crown to the distolingual corner.

Mesiolingual-distobuccal crown diameter: Defined as maximum distance from the mesiolingual corner of the crown to the distobuccal corner

Mesiobuccal-distolingual cervical diameter: Defined as maximum distance from the mesiobuccal corner of cemento-enamel junction to the distolingual corner.

Mesiolingual-distobuccal cervical diameter: Defined as maximum distance from the mesiolingualcorner of cemento-enamel junction to the distobuccal corner.

The measurements were taken by one person. All values were rounded to two decimal places. All samples were analysed using student T test. Data obtained were further analysed using stepwise discriminant functional analysis.

Results

A total of 16 measurements of each cast was taken in this study. Four diagonal measurements of each tooth was taken with two cervical and two crown measurements of both the sides.

Each measurement was taken twice by the same observer at different intervals of time to check for inter observer error. There was no statistically significant difference between the first and second observations.

An independent two sample t-test was done to test whether males were significantly different from females.

Table 1 shows percentage of sexual dimorphism, P values, t values for MBDL and DBML crown and cervical diameters for all the teeth of both males and females included in the study. In MesiobuccalDistolingualdiameter,right canine crown, right molar crown, right molarcrown cervix, left canine crown, left molar crown, left molar crown cervix were statistically significant between males and females ($P < 0.05$)

In DistobuccalMesiolingualdiameter right canine crown,left canine crown, left molar crown and left molar crown cervix were statistically significant between males and females ($P < 0.05$).

Percentage of sexual dimorphism was maximum for left canine crown MBDL, followed by right canine crown MBDL, left canine crown DBML, and right canine crown DBML.

Accuracy of classification results was 68.3% for males and 65% females and the overall was 66.7% (Table 2)

Stepwise Discriminant Function Analysis

Discriminant functional analysis is used to determine which continues variables discriminate between two or more naturally occurring groups.

Discriminant function score (Z) for gender assessment = 0.084(RtCanCrMBDL) + 0.458(RtCanCrDBML) + 0.062(RtCanCerMBDL) – 1.230(RtCanCerDBML) + 0.493(RtMolCrMBDL) + 0.018(RtMolCrMBDL) – 0.279(RtMolCerMBDL) – 0.501(RtMolCerDBML) + 1.353(LtCanCrMBDL) + 0.282(LtCanCrDBML) – 1.135(LtCanCerMBDL) + 0.364(LtCanCerDBML) + 0.064(LtMolCrMBDL) + 0.202(LtMolCrDBML) + 0.603(LtMolCerMBDL) + 0.210(LtMolCerDBML) – 11.229

If the discriminant score is (Z) is below the sectioning point, individual is classified as female and if the score is above sectioning point, individual is classified as male.

Discriminant function analysis (Table 3) provides coefficients and sectioning points for each function to determine sex. The group centroids provides the average discriminant scores for each sex. Sectioning point is the average of male and female group centroids. The sectioning point for male and female was calculated to be 0.0. Raw coefficients are the discriminant function coefficients used to calculate the discriminant score.

Discussion

Sex determination is one of the important steps in building the biological profile of the skeletal remains [16].It is of significance in mass fatality cases where bodies are damaged beyond recognition. In situations where only jawbone fragments with teeth are found, sex determination is possible only with the help of teeth [17]. Teeth being resistant to postmortemdestruction,can be used as a tool of reconstructive identification particularly in cases of major calamity [10].

Even though DNA profile gives accurate results, measurement of linear and diagonal dimensions such as anthropometric or odontometric parameters can be used for sex determination in a large population because they are simple, reliable, inexpensive, and easy to measure [14].As most teeth complete development before skeletal maturation, dentition makes a valuable sex indicator especially in young individuals [18].

Teeth are the most durable structures and highly resistant to post-mortem insults in the body which make them to be used in various forensic odontological studies for sex determination. Since the other skeletal parameters like pelvis and skull used as an indicator of sex are destroyed or fragmented, dentition is used in gender determination[12,19,20].

It is known that differences in odontometric features are seen in specific populations and also within the same population. So it is necessary to determine specific population values to make identification possible based on dental measurements[21]. In the present study maxillary canine and first molar are used in the assessment of sex in Chennai population.

Linear measurements have been routinely used in forensics for gender determination. Previous study done with linear measurement showed mandibular canine more dimorphic, followed by maxillary canine and maxillary central incisors in all the three dimensions[22].Since linear measurements are affected by conditions like attrition, crowding, tooth rotations, any mesio-occlusal, disto-occlusal fillings, this prevents one from taking accurate linear measurements. In these situations diagonal measurements can be used in determining gender[13].It was proposed that one of the advantages of diagonal measurementsof molars is that the diagonal axes do not conincide the contact points of the crown [12].

In this study, the diagonal tooth measurements were higher in males than females. The results were in accordance with previous studies by Prabhu S et al[16], JL Anderson et al[23], MA Hashim et al[24].In mesiodistal dimensions Khangura *et al*. [25] and Howe *et al.*[26]found that of male dentition are greater than those of females.This could be because males typically have larger dentine and pulp dimensions than females, while marginal enamel thickness was similar in both sexes [27].

The canine crown measurement was found to be more sexually dimorphic than the other measurements taken in this study. In a study conducted by Hashim HA, Murshid ZA where they evaluated 720 teeth in Saudi population they found that canines were the only teeth to exhibit dimorphism[24]. In another study conducted in Japanese population Minzuno reported that maxillary canine showed a higher degree of sexual dimorphism compared to the mandibular canine [28].Otuyemi and Noarshowed dimorphism in maxillary canine bilaterally [29].

In a study done in Turkish population, diagonal measurements of canine showed greater accuracy rate with MBDL measurements being more reliable[30]. The percentage of sexual

dimorphism was maximum for MBDL crown diameter of left canine (5.08%) followed by MBDL crown diameter of right canine (4.28%) and least for DBML cervical dimeter of right canine (0.77). The results were different in previous studies which showed Cervical diagonal diameters of molars to be more sexually dimorphic than crown diagonal diameters [12,15].

After analysing with discriminant functional analysis it is seen that the accuracy rate of gender determination in this study was higher in males (68.3%) than females (65%). And the overall accuracy rate of this study is 66.7%. In a study by Rao *et al*. 88% accuracy of sex identification was reported [31].

It's always seen that tooth size or odontometricsis under considerable influence of the environment. Such measurements are, therefore, population specific, and do not apply to the world at large [32].

Conclusion

Forensic odontology is an inexpensive and easy way of identification of persons from dental remains. Teeth are considered as supplement and adjunct in sex identification and is not recommended as the sole indicator of sex.

Diagonal measurements can be taken in situations where linear measurements cannot be taken as in attrition, crowding and orthodontic anomalies.

To conclude MBDL and DBML crown and cervical diameters are reliable indicators and can be used in sex determination. In future studies, larger samples from diverse populations should be analysed to enhance the reliability of this parameter.

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Background: Mandibular fracture is the most common site of fracture involved in facial bones following nasal bone. Despite many reports, about the incidence, diagnosis and treatment of mandibular fractures there is limited knowledge about the specific type or pattern of mandibular fractures in India. This study aims to evaluatethe percentage of fractures occurring in various regions of mandible and to examine the etiology of mandibular fractures using Orthopantomogram (OPG).

Objective: The etiology and pattern of mandibular fractures vary considerably among different study population. This study presents to delineate the etiology and predictable patterns of mandible using orthopantomogram. The reason for the present study is to correlate the etiology of mandibular fractures with anatomic location of fracture and to gain knowledge to guide surgeons for timely management of mandibular fractures.

Materials and methods: This study comprised radiographic evaluation of 70 mandibular fractured OPGS were taken for routine investigation. The type of mandibular fracture present in each OPG was identified and the cause for the fracture was retrospectively analysed. The results obtained were tabulated and recorded.

Result: The present study is done to evaluate the probability of occurrence of mandibular fractures in different anatomic location and identifying the type of mandibular fracture with proper history taking. Out of 70 fractured OPGs assessed, the most commonest site of fracture in mandible is parasymphysis region(34%) followed by body(15%),sub condylar(10%) and angle(2%) respectively. On tracking the medical history of patient, it was

found that most mandibular fractures occurred due to road traffic accidents(50%) and fall(35%). Condylar fractures are common due to physical force of injury.

Conclusion: In centres where OPG or extra oral radiograph facility is unavailable, a proper history taking with clinical examination could assist the clinicians for effective diagnosis and timely management of orofacial fractures.

Introduction

Injuries of the maxillofacial region represent one of the most arising health issue throughout India[1]. Maxillofacial injuries include soft tissue injuries, maxillary fractures, mandibular fractures and zygomatic fractures which are the common group of injuries treated by oral and maxillofacial surgeons [2]. The mandible is one of the most unique bone having a complex role in aesthetics of face and functional occlusion[3]. Because of the most prominent position of lower jaw in face, mandibular fractures tend to be the most common fractures of facial skeleton.[4] . In general, mandibular fractures have a higher adolescent and young adult age distribution and male predilection of occurrence which is attributed due to work in outdoor occupation thus becoming exposed to more Road Traffic Accidents(RTA)[5].The other causes of mandibular fractures include assaults, falls and the other miscellaneous causes include attack by animals, sporting injuries and industrial accidents[6]. Mandibular fractures can involve only one site or can often involve multiple regions simultaneously [7].

Therefore for each patient the combination of above mentioned factors determine the possibility of a mandibular fracture. Hence a clear understanding of different patterns and etiology of mandibular fractures is necessary for maxilla facial surgeons to plan the treatment for these kind of maxillofacial injuries.

This study aims to delineate the aetiology, frequency of anatomic distribution and the correlation between aetiology and anatomic location of fracture as an retrospective analysis.

Materials and methods

This study involves a retrospective analysis of medical records of patients who reported to Saveetha Dental College with the history of trauma wherein they are advised to take an OPG to detect the intensity and anatomic location of mandibular fracture. The medical records and

OPGs of these patients with facial trauma were retrieved and reviewed over the last two years. A total of 70 fractured OPGs were identified to have some form of mandibular fracture out of 1200 OPGs taken over a period of two years. The complete medical records of these 70 patients who had mandibular fractures were obtained that included case history, radiographs taken, photographs and if any surgical procedures performed were noted. Then data was analysed based on parameters of age, sex, mechanism of trauma, number and anatomic location of fractures.

Results

70 patients included in the present study were divided into groups based on age (1-10 years;11-20 years;31-40 years;41-50 years and 51-60 years) and according to sex male and female. Mechanism of trauma was recorded and classified as Road Traffic Accidents(RTA); fall; assault and miscellaneous. Anatomically the mandibular fractures were classified into Condylar; Coronoid; Sub condylar; Body ; Angle and Parasymphysis regions.

Out of 70 patient's OPGs assessed 50 were males(71.4%) and 20 were females(28.57%) with a male : female ratio of 20:1. The age of the patients ranged from 1 to 57 years with the mean of 27.09 years. The mean age formales was 26.39 years and for females it was 32.5years.

We found a peak occurrence of mandibular fractures in younger adults of age 21-30 years which was followed by 31-40 years,11-20 y3ears,41-50 years and 1-10 years of age group. Amongst the males the most common age of occurrence was 21-30 years while in females it was 31-40 years.

Incase of aetiology, RTAs were most common(34%) followed by fall(25%) which is in turn followed by assault(9%) which is followed by miscellaneous causes of(2%) respectively that included attack due to animals, industrial accidents etc. The data for causes of fractures categorized by gender showed that RTA(65% in males and 70% in females) was the most favourable etiological factor irrespective of gender. The second most commonest cause of fracture in males was fall(25%) and assault(9%) while in females the second most commonest cause was fall(30%) alone.

Amongst the anatomic location of mandible,the most frequently involved site is Parasymphysis region with(34%) of total mandibular fractures. This was followed by Body(15%);Sub condylar(10%);Angle (9%) and Condylar(2%) fractures respectively. The coronoid fractures are least common to occur which accounts for 0% of total mandibular fractures.

Out of patients with RTA, the parasymphysis fracture was predominant combination of fracture site involvement, followed by body. In case of fall patients the most common part of fracture in mandible was body followed by angle region whereas in case of patients with assault the most common region of fracture involved was Condylar and Sub Condylar region respectively.

Discussion

Regardless of the geographic areas, injuries of body are more common to occur [9]. Maxillofacial injury occurs in approximately in 5-33% of patients experiencing severe trauma which is often associated with loss of function, disfigurement, severe morbidity and significant financial cost for management [10].

Amongst the facial bone injuries the second most common fractures tend to occur in mandible following nasal bone [11]. The mandible is the only facial bone that has mobility amongst the other facial bones [12]. Hence the fracture in this region is never left unnoticed because it is very painful, pain that worsens with masticatory and phonation movements [13]. The patient may also complain of facial asymmetry that may lead to deformation of face whichis caused by displacement of dental occulusion or Tempero Mandibular Joint [14]. If not identified and treated these lesions may lead to severe aesthetic and functional dysfunction [14].

Mandibular fractures occur in all ages and all races in a wide range of geographic boundaries [15]. This result of present study of patients with mandibular fractures, who were treated in Saveetha Dental College are largely in agreement with those previous reports, particularly with regard to age and gender of the patient.

The finding was that the age group 21-30 years constituted the highest frequency of mandibular jaw fractures. Trauma is considered as the most common cause of fracture in these age group as their aggressive nature and careless driving on roads(Figure No 8). It has been also estimated that there is a male predilection of mandibular fractures than compared to the females. This is due to the fact that this group is more prone to road traffic accidents since they drive vehicle carelessly and more likely to be involved in violence.

In present study, the most commonest site of fracture is parasymphysis region (Figure1) which is generally due to Road Traffic Accidents .They are followed by Body, Sub condylar fractures , Angle, Condylar fractures and coronoid fractures respectively. It is found that Condylar fractures are common due to physical force of injury. In addition to that Condylar fractures occurs in combination with parasymphysis fractures. In case of fall patients the most commonly involved site of fracture was parasymphsis followed by body and angle of mandible.

Mandibular fractures are common in all races and all age groups of people. It is hoped that such assessments as the one presented here will give a valuable piece of information to government agencies and healthcare professionals involved in planning future prevention of these kind of injuries.

Conclusion

On correlating the etiology with the anatomic site of mandible, a clear history taking is necessary by clinician for immediate management to elicit the area of fracture in mandibular region before an Orthopantomogram could be taken where in the patient is pshycologically affected by pain. Furthermore etiology also aids in planning of surgical treatment.

Since the main cause of these fractures proved to be Road Traffic Accidents, any efforts made to enforce traffic and safety rule in roads and improve traffic culture can be made effective to promote the present situation.

Abstract

Introduction: To determine the incidence of Neurosensory disturbances of lingual nerve following surgical removal of impacted lower third molar and compare the type of impaction to the incidence and duration of Neurosensory disturbances.

Materials and Methods: 20 patients were selected and surgical removal of impacted lower third molar was done using Conventional Ward's incision and elevating the buccal flap. Neurosensory disturbances of lingual nerve were recorded periodically over telephonic conversations with the patients.

Result: Out of 20 patients, two patients were diagnosed having prolonged Neurosensory disturbances in lingual nerve. It was found that one patient had recovered while another is still under follow up. Hence, the overall incidence rate was found to be 5%.

Conclusion: It can be concluded that neurosensory disturbances of lingual never mainly depends upon the anatomical variations of lingual nerve, surgeon's inexperience and the type of impaction.

Key Words: *Mucoperiosteal flap, Odontomy, Ward's incision, Paraesthesia, Lingual nerve*

Introduction

Impacted teeth can be defined as those teeth whose normal eruption is prevented by adjacent tooth, overlying bone or soft tissue, malpositioning and lack of space in the arch, or other impediments. Impacted mandibular 3rd molar is one of the most common findings which are detected on routine dental checkup. However the patient seeks treatment whenever there is pain, swellings or another discomfort [1].Although the overall complication rate is low and most complications are minor, third molar removal being most common procedure that those minor complications may be significant. Therefore, efforts made to minimise intraoperative or postoperative complications will have a significant effect in terms of enhancing patient Outcome [2].Mandibularthird molar is situated at the distal end of the body of the mandible where is connection with relatively thin ramus. In mandible, there is a weak region where the fracture can occur if the applied force exceeds the limit during impacted wisdom tooth elevation without preliminary and adequate removing of surrounding bone.Impacted mandibular third molar teeth are in close proximity to the lingual, inferior alveolar, mylohyoid, and buccal nerves. During surgical removal of impacted lower third molar, both lingual nerve and inferior alveolar nerve are at great risk of damage [3]. If the damage occurs it may result in serious complications. Majority of these injuries result in transient sensory disturbances. In some cases, permanent paraesthesia (abnormal sensation), hypoesthesia (reduced sensation), dysesthesia (unpleasant abnormal sensation) can occur. These sensory disturbances as a result of injury can cause irritation for the patient, may result in speech and mastication and thus adversely affect the patient’s quality of life. They also constitute as one of the most frequent causes of complaints and litigation [4].Surgical removal of impacted lower third molar is one of the most common procedures performed in maxillofacial surgery clinics. The surgical removal of impacted third molar is often associated with some complications like pain; swelling, bruising and trismus.These complications are usually unexpected and unacceptable for the patients who weren't warned before the procedure. Hence, incidences of neurosensory disturbances in Inferior alveolar nerve and lingual nerve are also noted commonly [5].The lingual nerve is morphologically very different from the inferior alveolar nerve. The lingual nerve being a posterior division of the mandibular nerve provides somatosensory innervation of the lingual mucosa through its wide range of mechanosensitive, nociceptive and thermosensitive afferent fibres. Jointly with the chorda tympani nerve fibres, a branch of the facial nerve, it provides information to the anterior two

thirds of the dorsum of the tongue and preganglionic parasympathetic innervation of submandibular and sublingual secretory glands [6]. Its location is medial and anterior to the inferior alveolar nerve in its passage between the medial pterygoid muscle and the ramus of the mandible, where the fibres meet the chorda tympani nerve. Lingual nerve then goes via the gingival sulcus of the lingual mucosa superficially to the surface of the gland and submandibular ganglion. It finally ends as a sublingual nerve located immediately below the mucosa of the tongue. During surgical removal of impacted lower third molar oral and maxillofacial surgeons should consider the following factors such as the lingual nerve's proximity to the third molar lingual cortical plate, separated from the cortex only by the periosteum and its variable anatomy [7]. The exact mechanism of lingual nerve damage during third molar surgery is controversial and amongst the most studies causes are lingual plate perforation and lingual flap trauma during ostectomy or tooth sectioning, usage of lingual flap retractor and supra-crestal incision because the nerve can be located in this region in some cases and may be sectioned.During surgical removal of impacted lower third molar the nerve is covered with a thin layer of soft tissue whereas inferior alveolar nerve runs within a bony canal[8]. When sectioned and seen the cut nerve ends retract apart, adjacent soft tissue is distorted and the nerve ends may become malaligned and trapped. Regeneration of axons across a gap will be less successful than if the nerve ends remain in apposition[9].Neurosensory disturbances in lingual nerve usually occurs because of depth of impaction, position of tooth, age of the patient, duration of procedure, surgeon's inexperience and raising lingual and distal Mucoperiosteal flap. Incidence of lingual nerve damage was found to be 0.9% in a study conducted by Carmichael FA et al and McGowan DA et al[10] and 1.1%, a study conducted by Jeevan Lata and Arunesh K. Tiwari[11]. This article aims at emphasising the importance of relation between the type of impaction, duration of procedure and neurosensory disturbances in the lingual nerve.

Materials and Methods

20 patients were selected from Oral and Maxillofacial Surgery Department of Saveetha Dental College. Healthypatients of age group between 18 and 50 were included and those who are medically compromised are excluded from our study.

The surgical removal of impacted lower third molar was done using conventional Ward's incision. To minimise the risk of neurosensory disturbances, only buccal flap was raised and

gutter in the distobuccal bone for maximum exposure of the tooth was performed. The bone removal was done with the help of motor-driven surgical bur under the constant irrigation of normal saline. Odontotomy procedure was done depending on the type of impaction and the path of removal of impacted tooth[12].Patient's discomfort was assessed by telephonic conversations after 6hours, 24 hours and 7days following surgical removal of impacted lower third molar. Patients complaining neurosensory disturbances were advised for regular follow up and observed until paraesthesia was resolved.

Results

Out of 20 patients, 6 patients were found to have neurosensory disturbances for more than 24 hours and 2 patients had it for more than 7days on postoperative evaluation. The overall incidence rate is 5% since a patient is still under follow up for recovery of neurosensory disturbances. However other factors may influence neurosensory disturbances the level and the type of impaction play a major role in determining the duration of neurosensory disturbances [13].

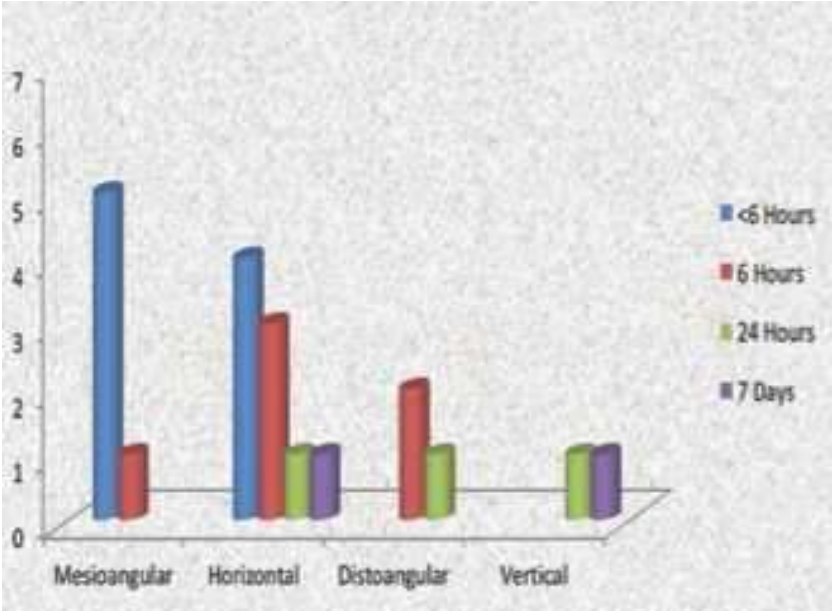
Table 1: Comparison of type of impaction and duration of neurosensory disturbances

Sl No	Age (Years)	Sex	Tooth Number	Type of Impaction	Duration of procedure (minutes)	Incidence & Duration of Neurosensory disturbances		
						6 Hours	24 Hours	7 Days
1	29	M	38	Mesioangular	14	Present	Absent	Absent
2	23	M	38	Mesioangular	11	Absent	Absent	Absent
3	29	F	48	Horizontal	16	Present	Absent	Absent
4	26	F	38	Horizontal	19	Absent	Absent	Absent
5	36	F	38	Vertical	22	Present	Present	Present
6	38	F	38	Horizontal	11	Absent	Absent	Absent
7	43	F	38	Mesioangular	10	Absent	Absent	Absent
8	39	M	38	Mesioangular	22	Absent	Absent	Absent
9	24	F	38	Distoangular	13	Present	Present	Absent
10	52	F	48	Horizontal at Root Apices of adjacent molar	45	Present	Present	Present
11	34	M	38	Horizontal	11	Present	Absent	Absent
12	21	M	38	Horizontal	9	Absent	Absent	Absent
13	45	M	48	Mesioangular	15	Absent	Absent	Absent
14	25	F	38	Distoangular	25	Present	Absent	Absent
15	20	M	48	Horizontal	15	Present	Absent	Absent
16	26	M	38	Distoangular	16	Present	Absent	Absent
17	26	M	38	Vertical	17	Present	Present	Absent
18	30	M	38	Horizontal	11	Present	Present	Absent
19	30	M	48	Mesioangular	9	Absent	Absent	Absent
20	45	M	38	Horizontal	8	Absent	Absent	Absent

Distribution of Type of Impaction

Out of 20 patients, most common type of impaction was horizontal(9) and mesioangular(6) impactions while vertical(2) and distoangular(3) cases have been recorded.

Graph 1: Comparison of type of impaction and duration of neurosensory disturbances



Discussion

The surgical removal of impacted mandibular third molars is the most commonprocedure performed by oral and maxillofacial surgeons. Sometimes surgeons may face various complications associated with the surgical removal of impacted mandibular 3rd molars. Among these complications most common postoperative complication is neurosensory deficit. It may affect either the inferior alveolar nerve or more commonly the lingual nerve that leads to numbness of the ipsilateral anterior two-thirds of the tongue and taste disturbance [14].

Neurosensory disturbances in lingual nerve are one of the most common complications experienced by dental surgeons in surgical removal of impacted lower third molar. They can have many serious psychological and legal implications [15]. The factors that contribute to these complications are type of impaction, depth of impaction, duration of procedure, sex and age of the patient.In our study, patient's age ranged from 20 to 55 years. Out of 20 patients, 60% of them were male and 40% were female. It had been found that more difficult the type of impaction more is the neurosensory disturbance. The overall incidence rate was found to

be 5% which is higher when compared to other studies. Initially Rood (1983) reported an initial incidence of 6.6%of neurosensory disturbances in lingual nerve[16]. In another study by Zuniga, the incidence of permanent injury to the IAN and LN has been mentioned to fall in the range between 0.4% and 25% and 0.04% and 0.6%, respectively [17]. In 2004, Tay and Go carried out a research study to determine the incidence of inferior alveolar nerve paraesthesia patients. In that study, an exposed inferior alveolar nerve bundle wasseen during third molar surgery and they concluded that such a situation indicates a high probability of an intimate relationship of the nerve with the tooth and thus carried a 20% risk of paraesthesia with a 70% chance of recovery by one year from surgery [18].Recently Cheung et al. carried out a study in which it was seen that of all the lower third molar extractions performed by various grades of operators, 0.35% developed IAN deficit and 0.69% developed LN deficit[19]. On comparing with radiological studies it has been concluded that mesioangular impactions are most common type and on surgical removal of those molars seldom causes paraesthesia [20]. It concluded that distoangular impaction was found to increase the risk of LN deficit significantly, wherein the depth of impaction was related to the risk of IAN deficit. It was also found that sex, age, raising of a lingual flap, protection of LN with a retractor, removal ofdistolingual cortex, tooth sectioning, and difficulty in tooth elevation were significantly related to IAN or LN injury.

Conclusion

Mandibular third molar extraction is a very commonly carried out procedure in day-to-day dental practice and is undoubtedly associated with few risks especially neural injuries and therefore in the light of the existing evidence, adequate preoperative evaluation of the patient and meticulous surgical technique with minimum handling of the lingual flap are of paramount importance to diminish the incidence of nerve injury. Although third molar surgery is a secure and low morbidity procedure, the risk of complications will always exist and it increases with increased surgical difficulty; hence, the patient should always be educated about the risks and benefits of surgery in order to ensure adequate surgical management of impacted mandibular third molar.

The lingual nerve injury after third molar removal is an important complication to consider before subjecting the patient to the intervention due to its remarkable incidence, its unpredictable cause and the significant discomfort it can generate. Depending on the severity

or chronicity of the injury, everyday life can be altered considerably. It is therefore vital to know the different risk factors involved in order to minimize the possible damage and report in detail to the patient before surgery to avoid medico-legal issues.

From our study and review of literature, it can be concluded that lingual nerve paraesthesia can occur with or without reflection of lingual flap and in spite of all the measures taken to protect it. It may be contributed to the fact of anatomical variations of lingual nerve. However if on clinical examination or radiographic presentation, it is pre-assessed that lingual nerve can be injured during surgical procedure, it should be well explained to the patient to avoid any legal litigation.

Association between Serum TriglyceridesLevel and Type 2 Diabetes

Vidhya.T.K[1],Naufal Rizwan[2],Saravana Pandian[3],

Graduate Student[1],Senior Lecturer[2], Department of General Medicine,Senior Lecturer[3], Department of Orthodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: The association between changes in triglycerides concentration over time and diabetics is unknown. The aim of this work is to find out an association between serum triglycerides level and type 2 diabetics.

Material and Methods: 50 type 2 diabetic patients are examined at saveetha medical college and serum triglyceride is measured in these patients.Triglycerides are bundle of fat found in bloodstream. The normal triglyceride level is around 100 to 150mg/dl. In diabetic patients triglyceride level was found to be elevated. The presence of hyperglycaemia stimulates the production of triglycerides and hence triglycerides levels are usually high in type 2 diabetes. The combination of high triglycerides, low HDL and central obesity are the hallmarks of the metabolic syndrome, which occurs in 80 percent of people with type 2 diabetes.

Result: Of the 50 patients examined, 41(82%) patients were found to have high serum triglyceride level. Lifestyle interventions such as diet, physical activity, weight loss, and smoking cessation are the integral part of diabetic management plan. There are several classes of medications used in the treatment of lipid and lipoprotein abnormalities associated with insulin resistance and type 2 diabetics.

Conclusion: In this study, there is a significant correlation between glycemic control and triglyceride levels in patients with type 2 diabetes in this population. Familiarity with this concept helps to diagnose lipid abnormalities in patients with poor glycemic control and preventing cardiovascular events in the high-risk patient.The raised TG levels leads to increased blood viscosity and altered fibrinolytic activity which leads to formation of hard exudates.

Key Words:*Triglycerides, Diabetic, Blood, Viscosity,Glycemia.*

Introduction

Type 2 diabetes mellitus is one of the prevalent diseases increasing health burden in both developed and underdeveloped countries. Prevalence of diabetes is noted to be higher in Asians (people from Pakistan, India, and China) as compared to Caucasians [1-2]. The significant factors responsible for this outstanding prevalence in Asians as compared to Caucasians are the sedentary lifestyle changes, rapid urbanization & adoption of industrialized food culture which leads to obesity and insulin resistance. In Pakistan, a recent study showed that the prevalence of non-communicable diseases like type 2 diabetes mellitus has doubled as compared to data collected in 2004. The health burden of diabetes in some of the semi urban area was found to be 14.6% [3]. Diabetes Mellitus is an array of metabolic dysfunction secondary to decreased insulin secretion or insulin resistance. The common threat of this disease is poor glycemic control predisposing to micro- and macro-vascular complications. Micro vascular complications include neuropathy, retinopathy, and nephropathy. Macro vascular complications are coronary artery and peripheral artery disease. Type 2 diabetes is linked with high cardiovascular morbidity and mortality. Cardiovascular risk in diabetes is determined by dyslipidemia and hypertension [4-5]. Dyslipidemia is one of the common condition associated with a poor glycemic control in type 2 DM. The pathogenesis of dyslipidemia in type 2 DM is a decrease in activity of lipoprotein lipase due to insulin deficiency or resistance. Under the action of insulin, enzyme lipoprotein lipase metabolizes lipids in a healthy individual. In type 2 DM, the relative insulin deficiency and decreased adiponectin causes decrease lipoprotein lipase activity resulting in high levels of low-density lipoprotein (LDL), triglyceride and low levels of high-density lipoprotein (HDL). Qualitative defects in LDL are also seen in type 2 diabetes including atherogenic, glycated or oxidized LDL further amplifying the risk of atherogenesis. [6-7]. Dyslipidemias is one of the modifiable risk factors for coronary artery disease in type 2 diabetes. Atherogenic or diabetic dyslipidemia is defined by a profile of low- and high-density lipoprotein and high triglycerides. It is an independent predictor of coronary artery disease or silent myocardial ischemia [3,8]. High triglycerides can be dictated by many factors including genetic or acquired [9]. To rule out other causes, we only include patients without any familial dyslipidemia or history of alcohol intake. As these two factors also play a role in increasing triglycerides as compared to polygenic etiologic like obesity, insulin resistance or diabetes mellitus [10-11]. The literature review was evident that hypertriglyceridemia is linked to high

glucose levels and increased risk of type 2 diabetes [12-13]. In our study, correlation of HbA1c with high triglycerides signifies HbA1c as a direct marker of hypertriglyceridemia and an indirect marker of risk assessment of coronary artery disease. It is important to understand the concept of insulin resistance and dyslipidemia predisposing to atherosclerosis [14-15]. Cholesterol lowering through secondary prevention by lifestyle changes or statin therapy has tremendously improved cardiac outcome in diabetes [5].

Type 2 Diabetes

Diabetes is a problem with your body that causes blood glucose (sugar) levels to rise higher than normal. This is also called hyperglycemia. Type 2 diabetes is the most common form of diabetes. If you have type 2 diabetes your body does not use insulin properly. This is called insulin resistance. Diabetes mellitus type 2 (also known as type 2 diabetes) is a long-term metabolic disorder that is characterized by high blood sugar, insulin resistance, and relative lack of insulin.[6] Common symptoms include increased thirst, frequent urination, and unexplained weight loss. Symptoms may also include increased hunger, feeling tired, and sores that do not heal. Often symptoms come on slowly. Long-term complications from high blood sugar include heart disease, strokes, diabetic retinopathy which can result in blindness, kidney failure, and poor blood flow in the limbs which may lead to amputations. The sudden onset of hyperosmolar hyperglycemic state may occur; however, ketoacidosis is uncommon. Type 2 diabetes primarily occurs as a result of obesity and lack of exercise. Some people are more genetically at risk than others. Type 2 diabetes makes up about 90% of cases of diabetes, with the other 10% due primarily to diabetes mellitus type 1 and gestational diabetes. In diabetes mellitus type 1 there is a lower total level of insulin to control blood glucose, due to an autoimmune induced loss of insulin-producing beta cells in the pancreas. Diagnosis of diabetes is by blood tests such as fasting plasma glucose, oral glucose tolerance test, or glycated haemoglobin (A1C). Type 2 diabetes is partly preventable by staying a normal weight, exercising regularly, and eating properly. Treatment involves exercise and dietary changes. If blood sugar levels are not adequately lowered, the medication metformin is typically recommended. Many people may eventually also require insulin injections. In those on insulin, routinely checking blood sugar levels is advised; however, this may not be needed in those taking pills. Bariatric surgery often improves diabetes in those who are

obese.Rates of type 2 diabetes have increased markedly since 1960 in parallel with obesity. As of 2015 there were approximately 392 million people diagnosed with the disease compared to around 30 million in 1985.(7,8)Typically it begins in middle or older age, although rates of type 2 diabetes are increasing in young people. Type 2 diabetes is associated with a ten-year-shorter life expectancy. Diabetes was one of the first diseases described. The importance of insulin in the disease was determined in the 1920s. The development of type 2 diabetes is caused by a combination of lifestyle and genetic factors. While some of these factors are under personal control, such as diet and obesity, other factors are not, such as increasing age, female gender, and genetics. (9,10) Management of type 2 diabetes focuses on lifestyle interventions, lowering other cardiovascular risk factors, and maintaining blood glucose levels in the normal range.

Serum Triglyceride

Triglycerides are a type of fat in your blood that is formed when you consume more calories than you need. Our body uses these fats for energy in between meals, storing them in your fat cells until they are needed. Normal triglyceride levels are less than 150 milligrams per decilitre. High triglycerides tend to show up along with other problems, like high blood pressure, diabetes, obesity, high levels of "bad" LDL cholesterol, and low levels of "good" HDL cholesterol (11,12). So it’s hard to know for sure which problems are caused by high triglycerides alone. Triglycerides are important organic compounds. Most of the fat we consume in our diet is triglyceride and so too is most of the fat we store in our body. Fatty acids contained in triglycerides are an essential source of energy for our cells. Triglyceride concentration can be measured in blood and may provide valuable information about metabolism and general health.(13) High levels may reflect underlying metabolic disorders and evidence shows that high blood triglycerides are associated with increased risk of heart disease. Making changes to our lifestyle can have a dramatic benefit. Some suggestions: Get more physical activity. Exercise can have a big impact on triglyceride levels. Experts recommend that everybody get at least 30 minutes of exercise at least five times a week. If you're out of shape, start slowly. Begin with a quick walk three times a week and then build up from there. Lose some weight. If you're heavy, shed a few pounds and try to maintain an ideal body weight. Exercise will help, but you also need to focus on diet. The key is to eat

fewer calories -- whether they come from fats, carbs, or protein. Focus on a diet that's high in fruits, vegetables, lean proteins, and low-fat dairy products. Cutting down on sugary foods -- like sodas -- could really help, too.Choose better fats. Pay more attention to the fats you eat. Eat fewer foods with unhealthy fats (found in meat, butter, and cheese) and trans fats (in processed foods and margarines), as well as cholesterol. Boost your intake of healthy monounsaturated and polyunsaturated fats, which are found in olive oil, nuts, and some fish. Studies have found that the omega-3s in fatty fish - like tuna, salmon, mackerel, and sardines -- are particularly good at lowering triglyceride levels. Because even healthy fats are high in calories, you still need to eat these foods in moderation.Cut down on alcohol. Even small amounts of alcohol seem to cause big spikes in triglyceride levels. Limit alcohol intake to one drink a day.(15) Triglycerides are a type of fat (lipid) found in your blood. Your liver makes triglycerides. You also get them through many of the foods you eat. In fact, after you eat, any extra calories that your body doesn't need right away are converted into triglycerides. These fatty substances are stored in fat cells. They are later released and circulate the bloodstream to be used as energy by cells. But as with LDL cholesterol, too much can be harmful. Most dietary fats are triglycerides. (14)

Material and Methodology

In this cross-sectional analytical study, we included 50 consenting patients of either gender from outpatient diabetes clinic Medical Unit(Saveetha Medical College), suffering from type 2 diabetes. Our age limit was 45 and above. Demographic information was collected from all patients included age, gender, body mass index (BMI), active tobacco use, active alcohol use, hypertension status, employment status and marital status. Relevant medical history including the presence of the type of diabetes, hypertension, pulmonary comorbidities, cardiac comorbidities (i.e. arrhythmia, myocardial infarction and coronary artery disease), thyroid abnormalities and the presence of familial dyslipidemia was also obtained. Our exclusion criteria were patients with missing data, taking statins or suffering from renal, hepatic, cardiac or thyroid diseases, and familial hypercholesterolemia.

Results

Of the 50 patients examined, 41(82%) patients were found to have high serum triglyceride level. Lifestyle interventions such as diet, physical activity, weight loss, and smoking cessation are the integral part of diabetic management plan. There are several classes of medications used in the treatment of lipid and lipoprotein abnormalities associated with insulin resistance and type 2 diabetics.

Discussion

Diabetes is a multifactorial disorder having a wide range of lipid abnormalities. In type 2 diabetes mellitus, there is an increased incidence of hypertriglyceridemia as compared to other lipid abnormalities [16-17]. This study evaluated the correlation between glycated hemoglobin (HbA1c) and triglycerides level and the results showed that there is a significant correlation between high HbA1c and high triglyceride. This may in turn help in predicting the triglyceride status of type 2 diabetics from the degree of glycemic control and therefore identifying patients at increased risk from cardiovascular events [18]. Diabetic dyslipidemia is associated with microvascular and macrovascular complications of diabetes, as has been shown in the studies conducted past few decades. High TG/HDL ratio in diabetic state is a significant risk factor for arterial stiffness and carotid atherosclerosis. Hence, atherosclerosis (due to high Triglycerides or TG/HDL) may contribute to the development of DKD. Hence, clinical efforts should be done to reduce triglycerides and to elevate HDL-C to reduce diabetic related complications contributed by dyslipidemia. Excretion of albumin (or microalbumin) in the urine is an early marker of renal dysfunction or damage in diabetes, causing proteinuria or nephropathy, which may lead to stage renal disease (ESRD) with high incidence .

Lebovitz suggested that there is a lipotoxic mechanism by triglyceride which interferes with gastric or neural pathway which regulates glycemic control [19]. In most of the studies, there is a correlation found between glycemic control and dyslipidemia [20]. In a recent study, it was evident that there was a positive correlation between HbA1c and high triglycerides and HbA1c can be used as a potent marker for dyslipidemia and mitigate the macro- and micro-vascular complications of disease [21]. Diabetes is an independent risk factor for developing

cardiovascular risk. Cardiovascular events are also the most common cause of death in diabetes [22-23]. Gluco-centric medications might help in improving glycemic control but their role in preventing cardiovascular disease is limited. According to the records mandated by American Association of Clinical Endocrinology (AACE). In 2016, approximately 660,000 United States residents will have a new coronary event as myocardial infarction or atherosclerotic cardiovascular event (ASCVD). It further mentions dyslipidemia as major risk factor for ASCVD. The contribution of triglycerides to CVD risk has been much debated in the past, with many important prospective studies observing an association between elevated triglycerides levels and CVD risk (in particular coronary risk), but also risk for microangiopathy, nevertheless, more recent studies gave different results, suggesting that this association might be weakened when adjustment for other risk factors was made. The pathogenetic mechanism undergoing these findings remains uncertain, and could be mainly related to triglycerides induced endothelial dysfunction through oxidative stress. By Cox analysis we demonstrated a direct association between long-term mortality risk and triglycerides levels; the association was strong and significant even after multivariate adjustment for traditional CVD risk factors including BMI, HbA1c, LDL-C, and medication use. This independent association with long term all-cause mortality support the idea that serum triglycerides could play a role in type 2 diabetic patients mortality risk.

Chronic complications of DM includes macro vascular complications like coronary artery disease, cerebrovascular disease and peripheral vascular disease along with micro vascular complications like retinopathy, nephropathy and neuropathy. Risk factors like duration of diabetes, glycaemic control (HbA1c),systolic blood pressure, dyslipedemias, smoking and microalbuminurias have been linked with complications of DM. Various studies have shown a positive correlation between elevated serum lipids (TG, LDL,TC) and macro vascular complications like ischemic heart disease. However, studies of association of elevated serum lipids with micro vascular complications like diabetic retinopathy (DR) have shown varying results. Serum lipids were measured in the fasting blood sample. Serum triglycerides (TG) and cholesterol were measured by enzymatic methods, Glycerol 3 phosphate oxidase N-ethyl sulphopropyl anisidine and cholesterol oxidase-peroxidase end point methods respectively. Serum high density lipoprotein (HDL) was estimated by precipitation method Polyethylene glycol precipitation method. Serum low density lipoprotein (LDL) was calculated using Fried

Wald's formula (LDL=TC-HDL-TG/5). TG is associated with the increased incidence of diabetic retinopathy.

Conclusion

In this study, there is a significant correlation between glycemic control and triglyceride levels in patients with type 2 diabetes in this population. Familiarity with this concept help to diagnose lipid abnormalities in patients with poor glycemic control and preventing cardiovascular events in the high-risk patient.The raised TG levels leads to increased blood viscosity and altered fibrinolytic activity which leads to formation of hard exudates. Also, TG incorporates into the cell membrane, altering its fluidity and permeability which leads to haemorrhage and oedema. This also leads to endothelial cell dysfunction and local inflammatory response releasing cytokines and growth factors which are responsible for neovascularisation in retina. So this article relates the risk of increased triglyceride level in diabetic patients.

Abstract

Introduction: Dental anxiety results in undesirable effects like turning away of dental treatment and increase stress among doctors that consequently have an effect on the treatment quality.Several studies have shown that, in medical practice audio-distraction was commonly usedto reduce the patients' pain and anxiety for short invasive procedures.Hence the aim of this study was to evaluate the effectiveness of listening to music using headphones as an audio distraction technique on behavior and anxiety management in children receiving dental treatment.

Materials and Method: The presentinterventional prospective study comprised of 60 subjects within the age group of6-12 who were advised for dental procedures. The patients were selected from the outpatient department and grouped randomly into group A and group B with 30 subjects in each group. The study group Acomprised of 30 pediatric patients who were given audio distraction aids. In the control group B, the treatment procedure were carried out without any distraction aids .The anxiety level was measured before and after the treatment for both the studyand control group using Wong Baker's anxiety rating scale and statistical analysis were made.

Result: Intergroup comparison showed highly significant difference in anxiety levels after the treatment.Intragroup comparison showed significant decrease of anxiety level from pre-operative and post-operative in both control and study group but it was more significant in study group. The statistical analysis showed significant decrease in anxiety level after the treatment in study group than in control group.

Conclusion: Within the limitations of the study, it was found that audio distraction technique proved to distract and reduce anxiety during dental procedures in pediatric patients.

Key Words: *Pediatric patients, Anxiety, White noise, Head Phones,Wong baker's anxiety rating scale, Distraction technique.*

Introduction

Dental anxiety among pediatric patients is a great challenge faced by every dentists in everyday dental practice. The child's uncooperative behavior may restrain the effective delivery of dental care which in turn may compromise the quality of treatment provided [1,2]. Behavior management techniques are meant to reduce the need for excessive and unsafe use of medications. Dentists have a wide variety of techniques available to them to assist in management of child with anxiety [3], such as tell-show-do, relaxation, distraction, systemic desensitization, modeling, audio analgesia, hypnosis and behavioral rehearsal[4]. Among this, traditional management such as papooseboard and hand over mouth technique can be successful. Management of children in the dental clinic is complex balancing act involving the child, parent and the dentist. To provide dental care for children good communication skills are necessary. A considerable percentage of children do not co-operate in the dental chair, causing an obstruction to delivery of quality dental care. This gives rise to behavior management techniques or alternatives to communicative management. Behavior management of the child patient is an intrinsic component of pediatric dental practice. Parents and care takers also play an important part in reducing the child's anxiety, allowing the dentist to perform the treatment and manage them [5,6]. Now no aversive techniques such as distraction are more popular. The success of distraction technique in medical setting and in adult patients is well organized, but literature reports limited data to assess the efficacy of distraction methodology in pediatric dental patients [1].Hence the aim of this study was to evaluate the effectiveness of listening to music using headphones as an audio distraction technique on behavior and anxiety management in children receiving dental treatment.

Materials and Method

Study Population

The present interventional prospective study comprised of 60 subjects within the age group of 6-12 years selected from the outpatient department and grouped randomly into group A as study group and group B as control group with 30 subjects in each group.

Inclusion Criteria

No previous dental treatment experience.

No systemic disease.

No learning disability.

Exclusion Criteria

Uncooperative patients.

Childrenwith any mental and physical disability.

Children with any trauma.

Materials

Wong baker's anxiety rating scale

Headphones

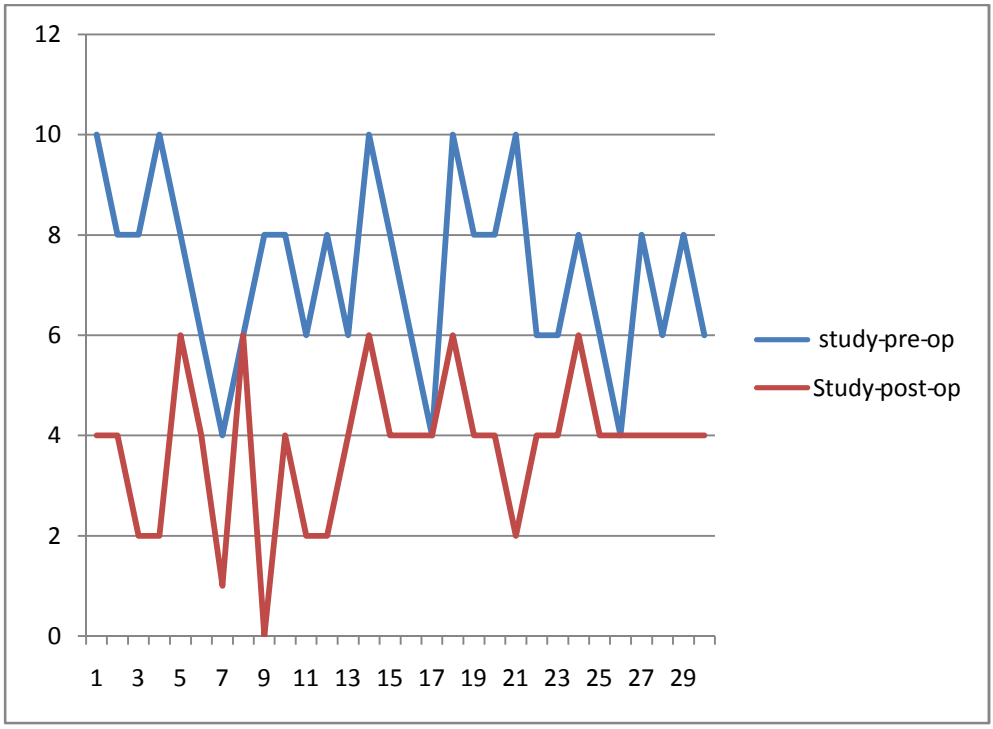
MP3 player

Method

The study was approved by the ethical committee of the institution and informed consent was obtained from the patients and their parents/guardians before the commencement of the study. The study group Acomprised of 30 pediatric patientswho were given audio distraction aidsi.e. Headphones with white noise a few minutes before the commencement of treatment.In the control group B, the treatment procedure were carried out without any distraction aids.

The volume of the music was maintained at 75 db to reduce the audible sound of hand piece to the patient. Whenever there was a need to communicate with the patient the volume was reduced. The anxiety score was measured before and after the treatment using Wong Baker's anxiety rating scale. Statistical analysis were made with unpaired t-test for intergroup comparison of anxiety scores and paired t-test for intragroup comparison of anxiety scores.

Graph 1: Anxiety score using audio distraction technique measured by Wong Baker's anxiety scale before and after the treatment



Graph 2: Anxiety score without using audio distraction technique measured by Wong Baker's anxiety scale before and after the treatment

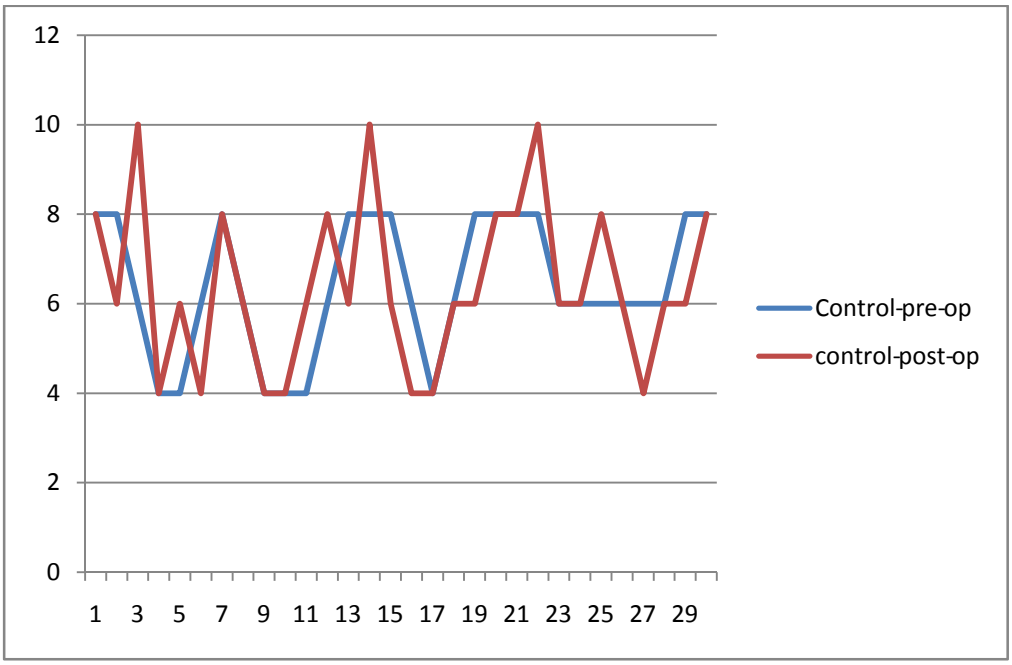


Table1: Inter group comparison of anxiety score

	Group	N	Mean	Std. Deviation	Mean diff	t value	p value
Pre-op	Study group	30	7.2667	1.77984	.66667	1.495	.140
	Control group	30	6.6000	1.67332			
Post-op	Study group	30	3.7667	1.47819	-2.36667	-5.841	**.000
	Control group	30	6.1333	1.65536			

Table 2: Intra group comparison of anxiety score

Group		N	Mean	Std. Deviation	Mean diff	t value	p value
Study group	Pre-op	30	7.267	1.780	3.500	8.69	*<0.001
	Post-op	30	3.767	1.478			
Control group	Pre-op	30	6.600	1.673	.466	2.97	*0.006

Post-op	30	6.133	1.655			

*- significant

**- Highly significant.

Result

Table 1 shows the mean scores, standard deviation and mean difference of pre-operative and post- operative anxiety levels between the groups (Unpaired t test), whereas, Table 2 shows within the groups (Paired t test). There was no much difference in distribution of subjects(based on anxiety levels) in study and control group ($p>0.05$).

Intergroup comparison showed highly significant difference in anxiety levels after the treatment. (Table.1)

Intragroup comparison showed significant decrease of anxiety level from pre operative and post operative in both control and study group but it was more significant in study group (Table.2)

The statistical analysis showed significant decrease in anxiety level after the treatment in interventional group than in control group (Fig 1, Fig 2).

Discussion

Dental fear of the patients is one of the most common reason to delay or avoid dental visits. Number of fearful people regularly cancel or fail to visit dentists. Patients with high dental fear, both children and adults, may prove difficult to treat. They require more time, and theirbehavioral problems which can result in a stressful and unpleasant experience for both the patient and the treating dental practitioner. If patients are not managed appropriately, it is more likely possible to establish what has been referred to as a ‘vicious cycle of dental fear’[6].

There are various pharmacological and non-pharmacological approaches in helping patients cope with dental anxiety. A caring and patient-centered approach in combination with various behavioral and psychological approaches play a vital role. This will yield superior short-term results as well as better long-term patient retention than the use of pharmacological methods.

Few non-pharmacological methods used for anxiety management includes, tell-show-do, rest breaks, signaling, positive reinforcement, diaphragmatic breathing, progressive muscle relaxation, cognitive restructuring, hypnosis[7]. These techniques have been in practice for many years and recent advancement in introduction of new distraction techniques includes music distraction and visual distraction techniques. A very few studies have been undertaken to evaluate the efficacy of distraction technique used for treating pediatric patients. Audio analgesia is one among the non-pharmacological distraction technique used to treat pediatric patients. In this study we have used white noise to reduce the pain and anxiety level of the pediatric patient. Objective measurement was done using Wong Baker's anxiety rating scale. The study results showed the effectiveness of using white noise in distraction and reducing anxiety in pediatric dental patients. The study result demonstrated that the anxiety levels were significantly reduced both with and without use of audio distraction. Interestingly,the use of audio distraction had reduced anxiety levelwhen compared with no usage.

White noise is a mixture of sounds of various frequencies [8]. It is also believed that White noise helps to increase the concentration and improve memory.This white noise of various frequencies have effect on mesolimbic midbrain, and this region of brain corresponds to the dopamine pathway [9]. Thus, white noise was reporedto reduceanxiety[9-10]. Moreover, the volume was kept at 75 decibel which was at 3/4 of the volume in the MP3 device which helped to decrease unpleasant noisecreated by dental hand piece or other anxiety inducing stimuli. Naithani et al evaluated audio- visual distraction in the managing anxious pediatric dental patients and reported an obviousdecrease in anxiety scores [9]. Jindal et al also found that audio distraction aids decreased level of anxiety in pediatric patients[10].Most children experience anxiety purely on the basis of psychological,social and environmental influences. Parents face special challenges because children with anxiety tend to be nervous, avoidant, annoying or exhausting[11-16].Ram et al reported that, audiovisual distraction technique provide as an effective distraction tool for the management of unpleasant behavior and distress that arises during dentalprocedures[17]. Singh et al reported that decrease the anxiety in pediatric patients to a significant extent, moreover patients had an overwhelming response to music presentations and wanted to hear them in their subsequent visits[18]. Prabhakar et al from his study conferred that, music reduced anxiety to some extent but not very significant, and stated that music distraction may be helpful

as an adjunct along with other techniques therefore further research needs to be done in this field using other non- aversive techniques and newer strategies should be devised to manage anxious pediatric dental patient [3]. Behavioral management of pediatric patients during dental treatment is most commonly used by almost all the dentists in which distraction technique plays a crucial role[19-22].Non- pharmacological methods of behavior management, particularly with difficult children proved to be more effective in reducing the complications caused due to anxiety[23-24].

However further research is required with greater sample size, involving different age group, giving choice of audio to the subjects and efficacy of other distraction methods such as visual and audio-visual techniques.

Conclusion

Within the limitationsof this study, it was found that the anxiety level of pediatric dental patients reduced with and without the usage of audio distraction after the treatment. Reduction in anxiety level with audio distraction proved more beneficial. Thus, it was concluded that managing pediatric patients with audio distraction aids especially white noise was an effective method for comfortable handling of anxious patients in dental clinic. Further more researches can be conducted with more invasive procedures to evaluate other better techniques in management of pediatric dental patients.

BMI Eating Habits and Related Factors among Students of Saveetha Dental College

Nathasha A/P Sivakumar[1], Gowri Sethu [2], Dhanalakshmi Ravikumar [3]

Graduate Student [1], Professor and Head [2], Department of Physiology

Senior Lecturer [3],Department of Pedodontics and Preventive Dentistry,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction

The last two decades have witnessed tremendous changes in the eating pattern of Indian population. There has been a revolution in adolescent's life style and eating pattern which can be largely attributed to changes in family and social environment. The changes in eating pattern may adversely affect their health. The aim of this research is to evaluate the BMI and eating habits among students in Saveetha Dental College.

Materials and Methods

100 students of Saveetha Dental College in the age group of 17-26 years were selected for the study and were divided into five age groups respectively. Age 17-18(group 1), 19-20(group 2), 21-22(group 3), 23-24 (group 4), 25-26 (group 5). The questionnaires were distributed to them and their food intake for 1 whole week was noted down, the collected data is tabulated for further interpretation of the study.

Result

Results were assessed statistically. Almost every fourth male student was overweight. Strikingly, 15% of female students were underweight. Highly-significant difference was found between average body mass index (BMI) of male and female students. Students' BMI did not correlate with average family income or with the frequency of taking breakfast.

Conclusion

Increasing the proportion of adolescents meeting recommended dietary and physical activity guidelines has been identified as an important strategy to contrast the epidemic increase in obesity, especially in western Countries. These students are more concerned about their appearance then their healthy diet intake. They are keener on finishing their works then taking proper care on their health.

Key Words: BMI, eating habit, healthy diet, obesity, underweight, carbonated drinks.

Introduction

The prevalence of obesity and overweight is quite high in the world population. According to a 2008 World Health Organization report, one billion of the world population is overweight and an additional 300 million are obese. Changing eating habits can be responsible for the rapid increase in these conditions, particularly among the young population [1].Previous studies have demonstrated that the adoption of an unhealthy lifestyle after becoming a university student, including smoking and alcohol consumption, and poor food preferences may be attributed to moving away from home, poor cooking skills, low income, and little time availability to engage in physically active recreation, and so forth. Such lifestyle changes lead to weight gain and an increase in body fat composition during the first year of the university education [2].

Obesity is associated with a variety of adverse health outcomes. An important risk factor for cardio metabolic disorders, cardiovascular diseases and premature mortality is obesity. There was evidence that suggest that diabetes, heart disease, osteoarthritis and high blood pressure may mediate the association between being overweight and health-related quality of life. In the last 20 years obesity has increased in prevalence worldwide. The majority of studies focused on overweight, obesity and less on underweight [3]. However, it is necessary to pay more attention to the negative effects that being too skinny have on health, being noted that the mortality risk is associated with underweight. A person may be underweight because of genetic or metabolic causes, lack of food, or diseases like hyperthyroidism, cancer, tuberculosis, gastrointestinal or

liver problems etc. But a person can be underweight because he/she wants it, as a consequence of the emphasis society puts on "thinness" (thinness, „silhouette“, the fact of not being fat). It can even lead to anorexia nervosa and bulimia nervosa. In case of anorexia nervosa, there is a loss of appetite, but sometimes the appetite stays while the patient refuses to eat and the body weight drastically drops. In case of bulimia nervosa, hyperphagia of large quantities of food in a short period of time (eating binge) take place, followed by self-induced vomiting, laxatives or diuretics, by periods of feeding cease (fasting) or intense physical exercises in order to prevent weight gain (binge and purge, approx. “satiation and deprivation”).Underweight individuals are prone to infections, osteoporosis. For women with severe underweight amenorrhea, infertility, complications during pregnancy, anemia, hair loss etc. can occur [4].

In 1993, the WHO assembled an Expert Consultation Group with a charge of developing uniform categories of the BMI. The results were published as a technical report in 1995.Four categories was established: underweight, normal, overweight, and obese. An individual would be considered to be underweight if his/her BMI was in the range of 15 to 19.9, normal weight if the BMI was 20 to 24.9, overweight if the BMI was 25 to 29.9, and obese if it was 30 to 35 or greater. Using linear regression, a BMI of 16.9 in men and 13.7 in women represents a complete absence of body fat stores.

The above 4 categories are similar to those suggested by John S. Garrow in 1981, but the terminology was changed. The terminology he used was “desirable” for a BMI up to 25, “grade I obesity” between 25 and 29.9, “grade II obesity,” between 30 and 40, and “grade III obesity” for BMI greater than 40.

The latter classification was based on Rosenbaum and colleagues’ own data obtained in a survey of an adult to 39.9 is class II obesity and a BMI of 40 or greater is class III obesity.

Over the past several decades, there has been an increase in BMI in the general population. This has resulted in predictions of a public health disaster. It should be recognized that in the United States during the period from 1960 to 2002 not only has the mean weight increased by 24 lbs. among men aged 20 to 74 years, but also the height has increased by about 1 in. We can then calculate that the weight increase per year has only been 0.57 lb. and as indicated above, this

could be due to an increase in lean mass rather than fat mass, or it may be a combination of the two. In women, there was a similar increase in weight and height.

In an earlier report, life-insured men up to age 40 years were reported to be 0.5 to 1.5 inches taller and 2 to 9 lbs. heavier for the same height in 1959 than those studied 50 to 60 years prior to 1959. Also, in the earlier study, the mortality rate was lowest in those with higher weight-to-height ratios. This was attributed to the presence in the population of wasting diseases such as tuberculosis that resulted in an increased death rate. Previously, a secular upward trend in height in adults in the United Kingdom also was reported. In addition, in a twin study in the United Kingdom, children in 2005 were not only heavier but also taller than 1990 norms, whereas their BMIs were essentially the same.

Overall, the history of changes in height and weight in Western European men and probably women has been that of an increase in both weight and height. In the 17th century, the average height of men in Northern Europe was ~5 ft. 3 in. It now approaches 6 ft. These data suggest that the BMI categories should be adjusted upward periodically to accommodate population-based changes. Improvements in mortality rates also suggest an adjustment would be useful.

The new terminology appears to be a bit presumptuous and careless because the BMI is not a direct measure of percent of fat mass, and the dynamic concept that those in the former “overweight” category are now in the “pre obesity” category invariably going on to “obesity” is not the case. Also those with a lower BMI initially, but with a dynamic weight gain over time, would have to transition through this category in order to become classified as “obese” regardless of the terminology.

There exists at present enormous concern amongst the population of the developed world regarding being overweight and obesity. This concern is generally justified by alleging health motives. The deeper motivation is, however, to a considerable extent, aesthetic. It is a slim body that is considered an attractive body in our society, amongst other things because, in a context of nutritional overabundance, it is more and more difficult to maintain a normal weight. In this cultural context all kinds of strategies to lose weight have flourished: hypo caloric diets, restrictive eating habits, nutritional compounds, pharmaceutical products and such extreme

measures as skipping certain meals. Thus, we find ourselves in the situation where more than 70% of the population of the western world admits that they are attempting either to lose weight or to maintain their present weight [5].

However, despite all these attempts to lose weight, figures show that the prevalence of obesity and being overweight has grown continually and alarmingly since the eighties. All of this would lead one to suspect that, although for many these strategies may be of use in the short term, this is not the case in the long term. Several studies seem to show this. Half of the people tend to give up hypo caloric diets within two months of starting them [6]. Furthermore, 95% of people tend to recover their initial weight between one and five years after finishing the diet. Similarly, it has been observed that some subjects may gain a surplus of additional weight with respect to their weight before the diet. Recent prospective studies show that attempts to lose weight seem to be associated in some subjects with a subsequent greater increase in weight (equal to or greater than 2 kg). Finally, weight and food can be the cause of great worry in some people [7].

The body mass index (BMI) is a value gained from the calculation of weight and height of an individual. A student's eating habits depends on their lecture schedules and availability of food inside or in the vicinity of the university area. As a result of the increase in the fast-food market and lack of appropriate food courts, students usually face meal skipping, inadequate variety of foods, and snacking [8].

Because calculation requires height and weight, it is cheaper and easy to use for clinicians and for the general public [9]. BMI can be used as a screening tool for body fatness but is not diagnostic. BMI does not only measure body fat directly, but BMI is slightly correlated with more direct measures the body fat obtained from skin thickness measurements, bioelectrical impedance, densitometry, dual energy x-ray absorptiometry (DXA) and other methods[10].

The purpose of this study was to quantify the prevalence of overweight and obesity among a sample of students in Saveetha Dental College and to describe their main eating habits. This study is part of a larger analytical investigation among the students of Saveetha Dental College, which estimated factors associated with quality of life.

A particular problem with BMI as an index of obesity is that it does not differentiate between body lean mass and body fat mass; that is, a person can have a high BMI but still have a very low fat mass and vice versa.

From an anatomical and metabolic perspective, the term obesity should refer to an excessive accumulation of body fat (triacylglycerol), and upon these grounds, the accuracy of the BMI as a determinant of body fat mass has been repeatedly questioned, because it clearly has limitations in this regard. Gender, age, ethnic group, and leg length are important variables. It should be noted that in population-based studies women generally have a BMI that is lower than that in men, even though their fat mass relative to their body build or BMI is considerably greater (~20% to 45%+).

The relatively poor correlation between percent of body fat mass and BMI in males has been known for many years and was clearly shown in a study in which percent of body fat was determined by a densitometric method. For men with a BMI of 27 in that study, the 95% confidence intervals for percent of body fat were 10% to 32%; that is, in this group, the percent of body fat varied from very little to that considered to be in the obesity range. (NIH-suggested criterion for obesity based on percent of body fat for men is ≥25%, and that for women is ≥35%)

Materials and Methods

- **Ethical Approval**

The present cross-sectional study was carried out after obtaining Ethical approval from the Institutional review board of Saveetha Dental College.

- **Study Design**

The survey was conducted in a single dental school in Chennai. This was one of the first study to assess the knowledge of BMI, eating habits and its related factors among the dental students. Since it was easy to recruit the study population from a single dental school, purposive sampling technique was chosen. A sample of 100 undergraduate students in a Saveetha Dental School, Chennai, India was included in the study.

The study was undertaken in two stages stage 1 and Stage 2. Stage 1 comprised formulating, designing, and validating the questionnaire, whereas Stage 2 tested the validated questionnaire among 100 undergraduate dental students.

- **Stage 1 (Designing and Validation of Questionnaire)**

A standardized self-constructed questionnaire was formulated by two investigators (NS, DR,). Both the investigators (NS, DR,) independently formulated the questionnaire, and after a consensus, they arrived at a final list of 15 questions. Initially, content validation of the questionnaire was performed by circulating the questionnaire to 100 students of Saveetha Dental College. A panel discussion was conducted among 10 qualified General dentists, and they had rated the questionnaire using content validity ratio.[14-16] There was a good agreement between the investigators, with a rating of >0.7. Finally, the questionnaire was distributed to 10 random General dentists for face validation, and it was evaluated using 5-point Likert scale.

- **Stage 2 (Testing of Validated Questionnaire)**

After the content and face validation, the questionnaire was distributed to 100 undergraduate students to complete the questionnaire. Distribution and collection of the questionnaire were done by one Graduate dentist (NS).

- **Statistical Analysis**

Data were collected and entered into SPSS software version (SPSS Inc., Chicago, IL, USA) 20.0 for percentages.

Results

Basic demographic data were shown. Male students were, in average, significantly taller and weighed more than females BMI 23.4±2.7 and 21.0±2.6 respectively. Mean BMI across genders varied within the normal weight range. According to BMI categories, three-quarters had normal weight (Table 1). Almost every fourth male student was overweight. In contrast, 15% of females were underweight. Obese students were the least common category with prevalence of only 1.5%. Students' BMI did not correlate with average family income or with the frequency of

taking breakfast. Mean BMI did not differ between those who ate breakfast and those who skipped it. In addition, BMI did not differ according to students' residence (with parents/alone/student dormitory. More than half of the students (57.3%) ate their breakfast regularly. One-third of subjects drank coffee every day, opposed to 27.3% who never drank it. Majority of students (80.1%) ate meat at least two times a week. Half of them ate one portion of fruits and vegetables daily (Table 2). There were no gender differences between consumption of fruits, vegetables, and meat.

TABLE 1: Distribution of Students According to BMI Categories

	MALE (NUM)	MALE (%)	FEMALE (NUM)	FEMALE (%)	TOTAL (NUM)	TOTAL (%)
UNDERWEIGHT	1	2.17	9	16.67	10	10
NORMAL	34	73.91	42	77.78	76	76
OVERWEIGHT	10	21.75	2	3.7	12	12
OBESE	1	2.17	1	1.85	2	2
TOTAL	46	100	54	100	100	100

TABLE 2: Distribution of Students According to Daily Consumption of Fruits And Vegetables

DAILY PORTION	FRUITS%	VEGETABLES(%)
ONE	46.8	46.6
TWO	22.7	25.6
THREE	8.9	9.8
FOUR	2	1.2
FIVE	1.9	0.9
MISSING	17.7	15.9

Discussion

Most of the Saveetha Dental College students were of normal nutritional status. Similar mean BMI was documented in students of different cultural backgrounds [11]. Obese students accounted for only 1.5% in our sample [12]. During 1997-2007, eating habits in the population of Serbia have been associated with irregular meals, decrease in fruits and vegetables consumption, along with related augmented intake of high-energy ingredients. In 2006, only half of the adults had had three regular meals per day while more than half were overweight [13].

In contrast, striking overall prevalence of underweight among Serbian students was recorded to be 10.6%. Proportion of females who were underweight was even higher (15.3%). Bodily proportions and BMI are certainly subject to emotional and physical well-being[14]. which is particularly addressed in concomitant eating disorders[15]. Also, university setting may have an important role in weight loss in the young adults as well. Academic pressures and time limits might often prevent students from regular meal consumption, leading to unintentional weight loss. Another possible explanation for such a high prevalence of underweight in female students might be related to eating disorders [16].

In this study, BMI in students did not differ among diverse place of residence during university schooling, implicating that parental involvement in meal regularity does not have impact upon weight change [17]. On the other hand, individuals who take care of meal frequency on their own, accomplish this in a responsible manner without experiencing dramatic weight losses or gains [18].

The importance of taking breakfast was emphasized because of the local circumstance that university schooling schedule covers the period from 8 am to 3 pm. Therefore, it is crucial that students have regular morning meal before the start of daily duties [19].

Since the students were filling in the questionnaire independently, we may consider reliability of data and potential information as well as recall bias. Additionally, there were no food intake diaries to quantify exact consumption of the ingredients [20].

Conclusion

Nutritional interventions among students have already shown positive results [21]. Therefore, promotion of healthy food consumption, with abundant fibers, whole grains, dairy products, and low energy-dense foods is needed. In addition, there is a growing demand for global health strategies which would encourage healthy body-image and figure; thus, these initiatives should mobilize the society on a national and international level [22].

Body Mass Index and Severity of Dental Caries among South Indian Children

Aslin Sanofer[1], Mahesh.R[2], Jayanth Kumar V[3]

Graduate Student[1], Reader[2], Department of Pedodontics, Reader[3], Department of Oral Medicine and Radiology

Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Sciences

Abstract

Introduction: Obesity is a medical condition in which excess body fat has accumulated to the extent that it has an adverse effect on health. Relative weight and body mass index (BMI) are nearly identical and are reasonable estimates of body fatness as measured by percentage body fat.The aim of this study was to find out the impact of body mass index and severity of dental caries among South Indian population. This study also assess the correlation between severity of caries in relation to body mass index among children.

Materials and Method: The prevalence of dental caries using dmft/DMFT index and BMI was assessed among South Indian school children population of age 8-12 years. A sample of 100 children werechosen.

Results: There was no significant correlation shown between BMI and Dental caries with a weak positive relationship between them among South Indian Children with the r value being 0.09.

Conclusion: This study showed that the obese children were prone to risk of more dental caries than normal individuals.

Key Words*: Dental caries, body mass index (BMI),dmft/DMFT , Children, Obesity.*

Introduction

The Body Mass Index (BMI) is a measure which relates patient weight and height.BMI is the metric currently in use for defining anthropometric height/weight characteristics in adults and for categorizing them into groups. The common interpretation is that it represents an index of an individual's fatness. BMI isalso widely used as a risk factor for the development of or the prevalence of several health issues (1). It is most ordinarily employed in decisive public health

policies.The BMI has been accepted in population-based studies and employed in process specific classes of body mass as a health issue.In 1972, Keys et al severely criticized the validity of Metropolitan Life Insurance published data per se, and the then-published tables of desirable weight for height, as well as the tables used to define people who were underweight or overweight (2). The term “obese” was rarely used in that era. Instead, Keys et al, using better documented weight for height data, popularized the Quetelet Index in population-based studies. They referred to it as the body mass index (BMI).

A higher BMI score indicates greater risk for developing serious health problems(3). WHO estimates that obesity is the fifth leading cause of mortality worldwide and now the rates have doubled within the last 20 years (4).The dietary changes are considered to be one of the potential causes for the observed increase in the prevalence of both overweight and obesity. Dental caries is multi-factorial disease and affects most of the world population.Dental disease ranks as the second most expensive disease. Recently, caries prevalence has increased in developing nations due to an array of factors, such as intake of sugary foods, low socio-economic status, exposure to fluorides, ethnicity, age, the limited access to oral health services and other lifestyle factors(5).

The decay-missing-filled (DMF) index or decayed, missing, and filled (restored) teeth (DMFT) index is one in every of the foremost common ways in oral medical specialty for assessing caries prevalence also as dental treatment wants among populations and has been used for concerning seventy five years (6). This index relies on in-field clinical examination of people by employing a probe, mirror and cotton rolls, and easily counts the quantity of decayed, missing (due to tooth decay only) and restored teeth. Another version projected in 1931 counts every affected surface, yielding a decayed, missing, and stuffed surfaces (DMFS) index.

Principle and rules in coding –DMFT are:

1- A tooth could have many restorations however it counted together tooth, F.

2- A tooth could have restoration on one surface and tooth decay on the opposite, it should be counted as decayed D .

3- No tooth should be counted over once, D M F or sound.

The maximum score of dmft is thirty two and minimum score of dmft is zero .The maximum score of primary teeth index is twenty .In mixed dentition, each child index is taken , one for permanent teeth and another for primary teeth.

This study gives details about prevalence and severity of dental caries among young children and its associated correlation with Body mass index.

Material and Method

The sample no of children was 100 whose age range were 8-12 years. Both the male and female were included .Data were collected through interview and a self-report questionnaire. The prevalence of dentalcaries were obtained using the WHO standard criteria. Weight and height were measured and BMI was calculated according to the formula: weight / height (Kg/ m2) units. BMI was categorized into underweight (BMI < 18.5), normal (BMI 18.5 - 24.9), overweight (BMI 25 - 30), and obese (BMI > 30). Information about relevant eating habits and brushing habits were added in the survey .The DMFT/ dmftand BMI values were noted(Table no : 1) and statistical analysis were calculated. The statistical analysis was done using SPSS version 17 and Pearson's correlationcoefficientwas calculated.

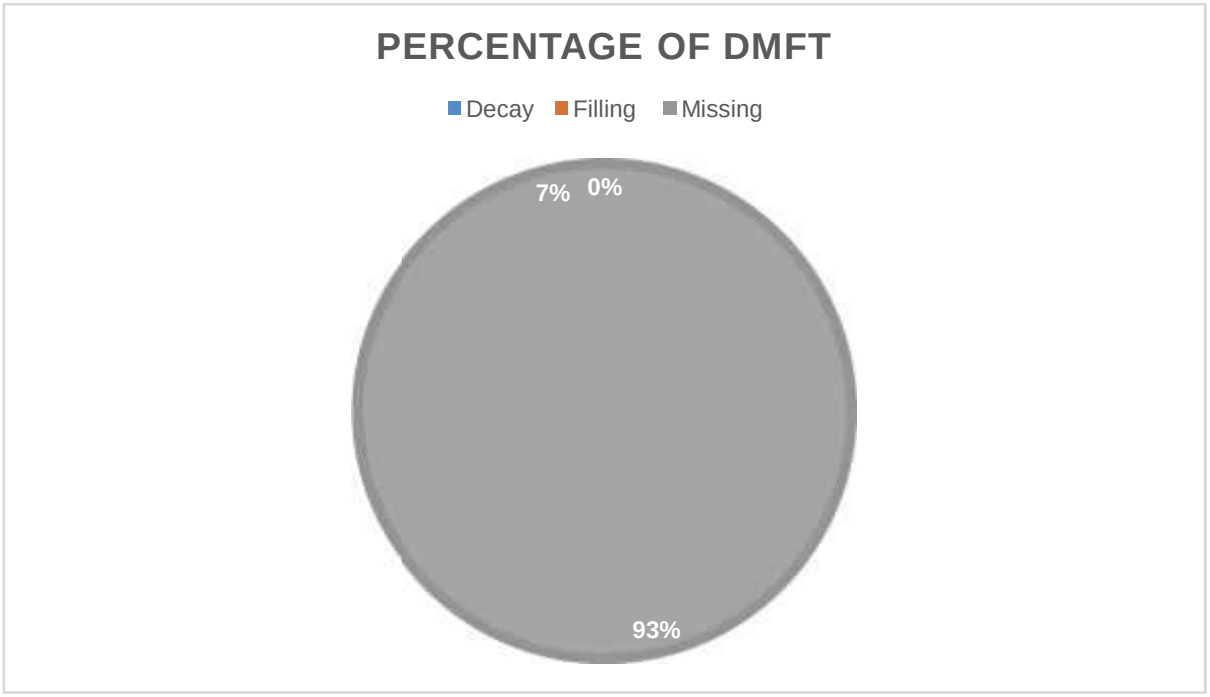
Distribution of study subject based on gender, BMI and dmft / DMFT

No,of,samples		100
	Males	43
Sex		
	Females	57
	DMFT,/,dmft	0.148
Mean,value		
	BMI	19.86

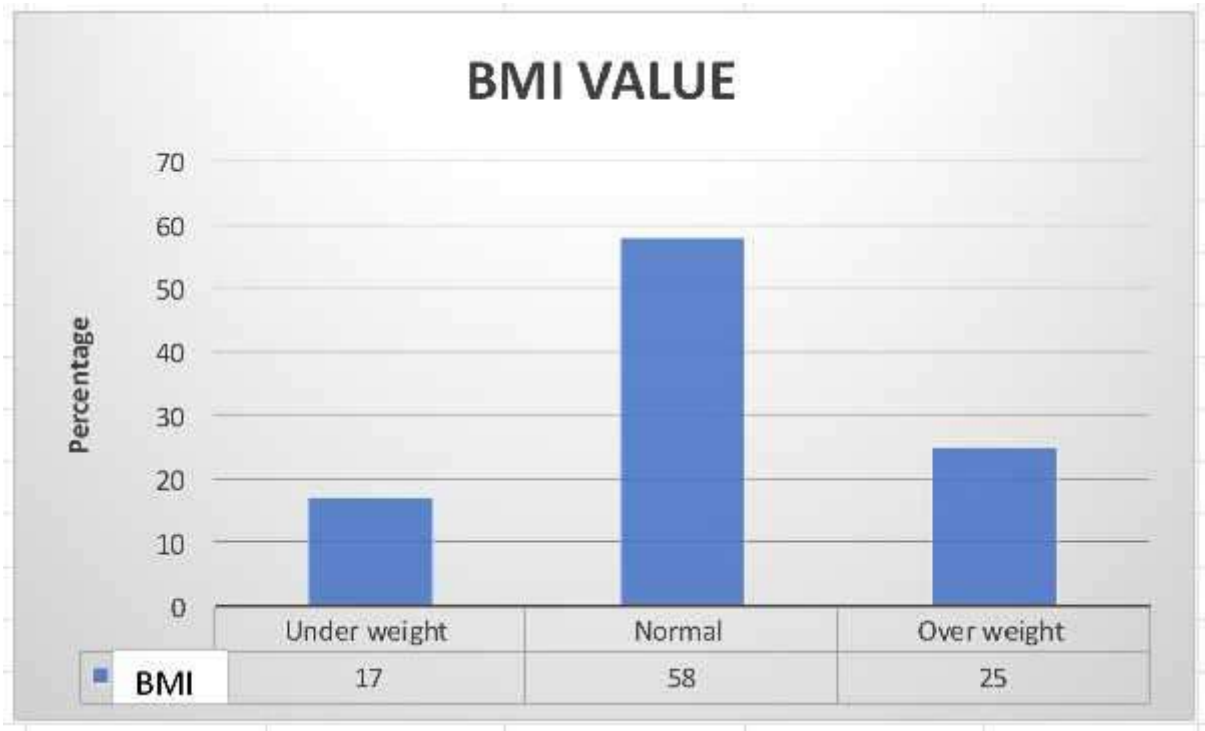
(**Table no : 1)**

Result:

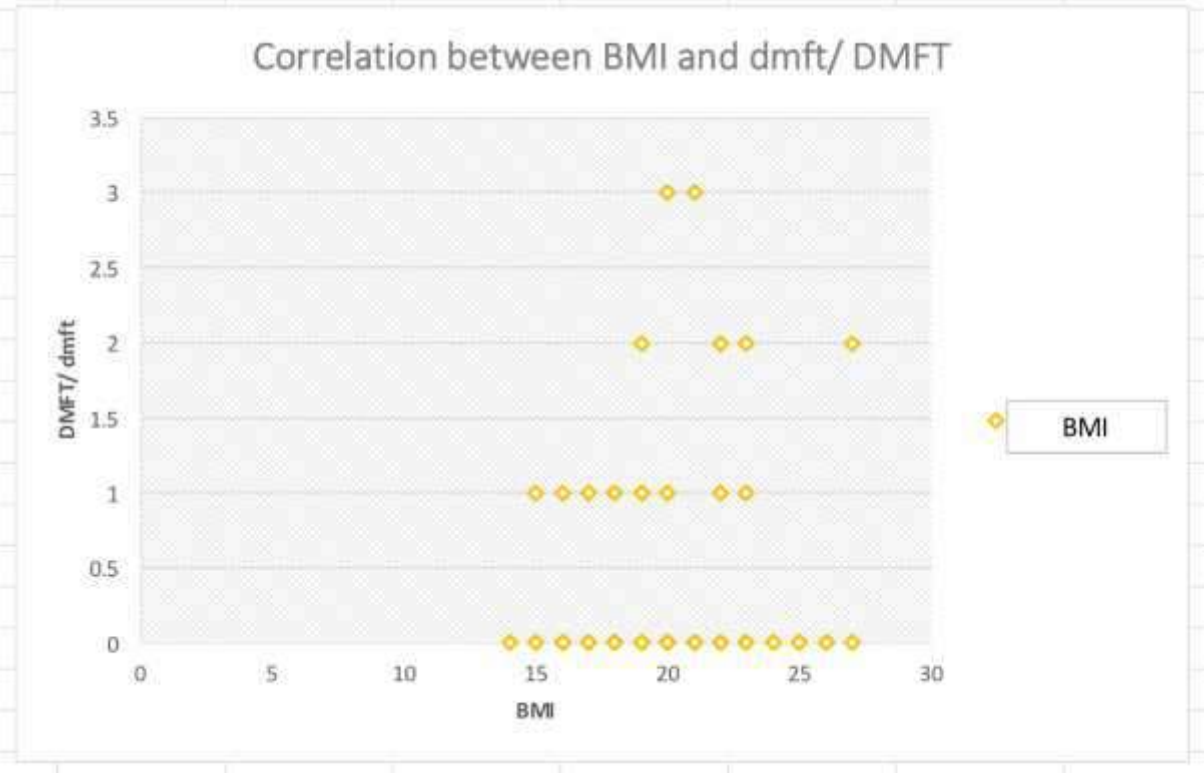
The prevalence of caries were found to be more in posterior teeth than anterior teeth . The mean DMFT/dmft was calculated as 0.148 and the mean BMI was 19.86. From the data the underweight children (BMI <18.5) was 35 and the mean DMFT/dmft score was 0.071. The normal weight children were 58 (BMI 18.5 - 25) and the mean score was 0.19. The overweight children with BMI > 25 were 5 with the mean score at 0.2. Pearson's correlation coefficient between DMFT/dmft and BMI was 0.09 indicating a weak positive correlation. High risk of caries were found to be more in permanent dentition than primary dentition.Both the gender was affected in the equal population.The obese or overweight children have more risk of caries due to mid snacking habits during school time and holidays.The missing and filling were found to be comparatively less than decay.



Graph 1 –Pie chart showing frequency of decay, missing and filled tooth/ teeth



Graph 2 - Bar graph showing average ideal Body weight percentage



Graph 3 – Scatter plot showing correlation between BMI and dmft / DMFT

Discussion:

In this study, we noticed a weak correlation between BMI and dmft / DMFT which was similar to other previous studies (7).The r value evaluated in this study were 0.09. (Graph no : 3). In this study, Dmft / dmft rate showed less risk in normal and under weightschool children where as higher risk in over weight school children (Graph no : 1& 2) .

In one of the recent studies , it is considered that clinical variables (dmft, DMFT) can be relevant predictors for the occurrence of dental caries in mixed dentition and permanent dentition.Caries lesions of primary teeth along with the consumption of carbohydrates (sweets) were associated with the occurrence of proximal lesions of permanent teeth in adolescents, and especially first permanent molars were affected.The combination of a large number of incipient caries, Streptococcus mutans and Lactobacillus acidophilus presence, represent a predictive model for

carious lesions in permanent dentition.The bacterial level (Streptococcus mutans, Lactobacillus acidophilus) is included with the highest accuracy in prediction models of caries in the permanent dentition.Increased frequency of tooth brushing associated with a higher socioeconomic level,education level and reducing snacks, are considered unfavourable elements for caries development in the permanent dentition.Mentioned aspects can become effective conceptual and lucrative opportunities to improve the child's dental management (8).

Forty-eight percent of studies reviewed found no association between dental caries and BMI; 35% found a positive association and 19% found an inverse association.Children who are overweight or obese have relatively high levels of dental caries.They also consume high levels of soda (9) and other energy-dense foods, many of which are cariogenic and obesogenic. Modeer et al. suggest that obese children are at risk of dental caries because they have reduced salivary flow which is associated with protein-deficient malnutrition(10). Obese children may well suffer from protein deficient malnutrition if their energy intake is made up of high carbohydrate, highly processed foods. Malnutrition could also predispose to dental caries; deficiencies in protein or energy foods may lead to protein-energy malnutrition, decreased salivary flow, calculus formation, high levels of caries and reduced growth(11).

Also Costacurta et al (12) suggest that BMI may not be the best measure of body fat composition when testing the association between dental caries and obesity. They suggest that misclassification of childhood obesity using BMI might account for the failure of studies to detect the association between child adiposity and dental caries. Present studies were found to be show a positive significant relationship between BMI and dental caries.The association between DMFT/dmft and BMI were also significant.

In a study conducted in India (13) among 350 school children revealed a negative correlation of $r=-0.023$ which was not statistically significant ($p>0.05$). Further their study had reported that mean DMFT values 4.9 ± 4.0, 4.6 ± 3.3, 2.7 ± 1.9, and 4.4 ± 3.0 for normal, overweight and obese respectively.

A similar study carried out by Bhayat et al (14) among 12 year old boys in fur geographical location in Medina, Saudi Arabia. The results showed that the mean BMI was 22.17 kg/m² (± 5.15); 41% had normal BMI, 25% were overweight and 30% were obese. The mean DMFT Score 1.46 (± 2.04). The participants in the normal BMI group had a higher prevalence of Caroes (57%)and mean DMFT was 1.92. Using a linear regression analysis it was found that overweight and obese participants had twice the risk of developing caries.

In a study America at al (15) in a cross sectional study of 1326 children who took part in the 2010 survey found that there was no significant difference in the DMFT and BMI. In a study conducted in Kerala (16) among 2000 school going children the mean BMI recorded was 26.87 ± 2.26 for the overweight children and 20.82 ± 1.48 for the normal-weight children. The mean DMFT for the overweight group was 3.90 ± 2.95 while that in normal weight was 3.36 ± 2.73. There was no statistically significant correlation between BMI and DMFT. In a broad study of 32461 pupils in China had reported a positive correlation between BMI and DMFT/dmft (24) . A study carried out in Japan showed that 23% of participants had no caries (DMFT=0),17% had few caries (DMFT =<3) 23% had many caries (DMFT=3.1-6.9) and 22% had many caries (DMFT>7). There was no siginificant correlation between DMFT and BMI
(17) . In a study done in Korea the mean DMFT had no correlation with BMI (18).In a study conducted in Chandigarh among 4493 school going children (19) it was found that a majority of children required restorative procedures for dental caries. There are reports in the literature to indicate that high DMFT score has a significant impact in the patient's perception of dental health (20).

Conclusion

The correlation between dmft / DMFT in relation to BMI shows a weak correlationof 0.09 which was similar to other previous studies.In our studies, the association between BMI and dmft/DMFT we're not statistically significant in the South Indian population. The dental checkup and medical health care awareness should be present for each individual or family functioning to prevent the early childhood caries and malnutrition or any multifactorial disease.

Abstract

Introduction: *V. vinifera* contains many phenolic compounds,which includes Anthocyaninsthat can be found in the skin of the berries, hydroxycinnamic acids in the pulp and condensed tannins of theproanthocyanidins type in the seed. The aim of the study is to evaluate the brine shrimp lethality assay of ethanolic extract of grape seed.The objective is to correlate the cytotoxicity results with the known pharmacological actions of the plant.

Materials and Methods: The present study was conducted to evaluate invitro brine shrimp lethality assay of ethonolic extract of grape seed and correlate cytotoxicity results with known pharmacological actions of the plant. Novel cytotoxic, pesticidal compounds can be isolated from plant based sources through the investigation of cytotoxic activity against brine shrimps. Twenty nauplii were added into three replicates of each concentration of the plant extract. After 24,48 hours, the surviving brine shrimps were counted and percentage of mortality was assessed.

Results: It shows that grape seed extract is highly toxic to brine shrimp with increase in concentration. It was observed that at a concentration of 1mg per ml 25% of mortality is seen in brine shrimp in 24 and 48 hours. At 2mg concentration 35% of brine shrimp were killed in 24 hours and 55% were killed in 48 hours, at 3 mg per ml concentration 60% of the brine shrimp were killed and at 48 hours 80% mortality was seen. At a concentration of 4 mg per ml 80%mortality of brine shrimp was noticed in 24 hours and at 48 hours about 85% mortality was observed. Finally, at 5mg per ml concentration about 100% of eggs (Larvae) of brine shrimp were killed and this concentration proves the larvicidal efficacy of the grape seed ethanolic extract.

Conclusion: Brine shrimp lethality assay is an economical and cost effective method for investigating the cytotoxic activity. Hence from the results it can be concluded that grape seed is a promising candidate against brine shrimp and potents cytotoxic activity.

Key Words:*Eggs of Brine shrimp, grape seed extract, cytotoxicity, lethality assay, concentration, larvicidal activity*

Introduction

Vitis vinifera(grape seed extract) is a species of *Vitis*, which is native to the Mediterranean region, central Europe, and southwestern Asia[1]. There are currently between 5000 and 10,000 varieties of *Vitis vinifera* grapes available in nature. The fruit is a berry, which is known as a grape; in the wild species it is 6 mm (0.24 in) diameter and ripens dark purple to blackish with a pale wax bloom; in cultivated plants it is usually much larger, up to 3 cm (1.2 in) long, and can be green, red, or purple (black).[8] The species typically occurs in humid forests and in streamsides.[2-3]

V. vinifera contains many phenolic compounds,which includes Anthocyanins that can be found in the skin of the berries, hydroxycinnamic acids in the pulp and condensed tannins of theproanthocyanidins type in the seeds[4].

Stilbenoids can be found in the skin and in wood.[9-10].Stilbenoids*Trans*-resveratrol is a phytoalexin produced against the growth of fungal pathogens such as *Botrytis cinerea* and delta-viniferin are another grapevine phytoalexin produced following fungal infection by *Plasmopara viticola*Anthocyanins*Vitis vinifera* red cultivars are rich in anthocyanins that impart their colour to the berries (generally in the skin).[5-6] The 5 most basic anthocyanins found in grape are:Cyanidin-3-O-glucoside **,** Delphinidin-3-O-glucoside**,**Malvidin-3-O-glucoside**,**Petunidin-3-O-glucoside**,**Peonidin-3-O-glucoside[7,14,15].

Innovation of antimicrobials has long paved the way for human health [8].Its well-known fact that various cell line studies are there to prove the cytotoxicity efficacy of the herbal extract [16].

Aim

The aim of the study is to evaluate the brine shrimp lethality assay of ethanolic extract of grape seed.

Objective

The objective is to correlate the cytotoxicity results with the known pharmacological actions of the plant.

Materials and Methods

Grape seed extract was obtainedfrom green stem Chem. Herbel extracts and formulations, Bangalore.

Brine Shrimp Lethality Assay

The eggs of Brine shrimp were procured from Philadelphia, USA. In a small water tank containing sea water, the eggs were incubated for 48 hours for hatching. Required light was provided with Philips 40 Watts lamp for 12 hours cycle. After 48 hours, the larvae were used for the experiments. The nauplii of Brine shrimp were challenged in different test tubes containing 10 mL of sea water and 20 larvae. To this, extracts of leaves at different concentrations (1, 2 3, 4 and 5 mg/mL) were added. After 48 hours, the viability of larvae was observed and mortality was recorded. Nauplii were considered dead when they were immobile and stayed at the bottom of the test tubes. The percent mortality of brine shrimp was calculated with the formula given below.

Results

[% mortality = No. of brine shrimp dead /No. of brine shrimp introduced x 100]

Table 1: Brine shrimp lethality assay of grape seedextract

Sample	Incubation Period	Concentration(mg/ml)				
		1 mg/ml	2 mg/ml	3mg/ml	4 mg/ml	5mg/ml
Grape seed extract	24 h	25	35	60	80	100
	48 h	25	55	85	85	100

The results obtained from different concentrations of brine shrimp lethality assay are given in table1. It shows that grape seed extract is highly toxic to brine shrimp with increase in concentration. It was observed that at a concentration of 1mg per ml 25% of mortality is seen in brine shrimp in 24 and 48 hours. At 2mg concentration 35% of brine shrimp were killed in 24 hours and 55% were killed in 48 hours, at 3 mg per ml concentration 60% of the brine shrimp were killed and at 48 hours 80% mortality was seen. At a concentration of 4 mg per ml 80%mortality of brine shrimp was noticed in 24 hours and at 48 hours about 85%

mortality was observed. Finally, at 5mg per ml concentration about 100% ofeggs(Larvae) of brine shrimp were killed and this concentration proves the larvicidal efficacy of the grape seed ethanolic extract.

Discussion

The brine shrimp lethality assay is considered a useful tool for preliminary assessment of toxicity. It has also been suggested for screening pharmacological activities in plant extracts. However, we think that it is necessary to evaluate the suitability of the brine shrimp methods before they are used as a general bio-assay to test natural marine products for pharmacological activity [17].

The shrimp lethality assay was proposed by Michael et al. [18], and later developed by Vanhaecke et al. [19], and Sleet and Brendel [20]. It is based on the ability to kill laboratory-cultured *Artemia* nauplii brine shrimp. The assay is considered a useful tool for preliminary assessment of toxicity [21], and it has been used for the detection of fungal toxins [22], plant extract toxicity [23], heavy metals [24], cyanobacteria toxins [25], pesticides [26], and cytotoxicity testing of dental materials [27].

On the other hand, although most researchers have made use of the hatched nauplii, other assays based on the inhibition of hatching of the cyst (encased embryos that are metabolically inactive) have also been used [28]. Brine shrimp lethality bioassay is a standard method to investigate cytotoxicity of herbal extracts. This method is cost effective hence easily employed in vitro to check the larvicidal efficacy of the plant extract[29].***Vitis vinifera*** is a species of *Vitis*, which is native to the Mediterranean region, central Europe, and southwestern Asian region[30,31].

The grapevine (*Vitis vinifera*) belongs to the family Vitaceae, which comprises about 60 inter-fertile wild *Vitis* species distributed in Asia, North America and Europe under subtropical, Mediterranean and continental–temperate climatic conditions. It is the single *Vitis* species that acquired significant economic interest over time; some other species, for example the North American *V. rupestris*, *V. riparia* or *V. berlandieri*, are used as breeding rootstock due to their resistance against grapevine pathogens, such as *Phylloxera*, *Oidium* and mildews. Indeed, a great majority of cultivars widely cultivated

for fruit, juice and mainly for wine, classified as *Vitis vinifera* L. subsp. *vinifera* (or *sativa*), derive from wild forms [*Vitis vinifera* L. subsp. *sylvestris* (Gmelin) Hegi][32]

The wild grapevine is a heliophilous liana growing generally along river banks, and in alluvial and colluvial deciduous and semi-deciduous forest [33]. It is distributed in a wide area from western Europe to the Trans-Caucasian zone and around the Mediterranean Basin, except the most southern infra-Mediterranean and non-Mediterranean [34].

The present distribution of the wild grapevine is highly fragmented, in disjoint micro-populations or metapopulations, with few individuals, at least in the western part of the Mediterranean Basin. Anthropogenic pressure on their natural habitats and pathogens introduced from North America during the second part of the 19th century, may explain the progressive decline of wild grape populations[34].

The '*Phylloxera* crisis' that affected European vineyards had a considerable impact on both cultivated varieties and wild grapes. As a result, modern wild grapevines are endangered and threatened with extinction [34]. The future of *Vitis vinifera* subsp. *sylvestris* represents a major stake in biodiversity conservation.

The cultivation and domestication of the grapevine appears to have occurred between the seventh and the fourth millennia BC, in a geographical area between the Black Sea and Iran[35]. From this area, cultivated forms would have been spread by humans in the Near East, Middle East and Central Europe. As a result, these areas may have constituted secondary domestication centres[36]

Indirect evidence of ancient winemaking[37] is provided by the discovery of significant quantities of vinification residues (tartaric acid) with terebinth resin in clay jars, dating back to the end of the seventh millennium BC. In the Near East, numerous archaeological grape seeds attributed to the cultivated grapevine were found in Chalcolithic and mid Bronze Age archaeological levels[38].

From the eastern Mediterranean areas, grape cultivation seems to have spread gradually westwards. In Greece and Crete, the beginnings of viticulture would have started during the fifth millennium BC[39].

In Italy, the most ancient testimonies of grapevine cultivation date back to the ninth century BC[40]. In Spain and in the Maghreb, the Phoenician influence during the first part of the last

millennium BC appears to have played a significant part in the establishment and development of viticulture and viniculture[41]. Finally, it is currently thought that the emergence of viticulture in France was concomitant with the foundation of Marseille (600 BC) by the Greek Phocaeans [39]. Viticulture seems to have extended rapidly in southern France from the fifth century BC. Important coastal exchanges and trading centres such as Lattes (Hérault) would have also played an important role in this process. After the Roman conquest, viticulture was well established in the Languedoc region, reaching its height between the end of the first century and the second century AD.

By way of the 'Narbonnaise' route, viticulture extended into Aquitaine (western France) during the first century AD. During this same period it also spread northwards, in the Rhône, Loire and Seine valleys [40]. When the wine production of the Narbonnaise area started threatening the hegemony of Italian wines, the Emperor Domitian ordered the destruction of half of the region's vineyards. However, it appears that the Emperor's edict (92 AD) was not applied[40, 41].

Archaeological investigations have revealed a considerable development of viticulture and viniculture between the first and the end of the second century AD. It is only approx. 300 AD that Emperor Probus withdraws Domitien's prescriptions. From the fourth century onwards, while the Christian faith spread its influence throughout Europe, viticulture and viniculture again experienced a geographical expansion.

Although this model of development, expansion and diffusion of viniculture and viticulture in France (and more generally for the north-western Mediterranean areas) is well documented from archaeological and historical points of view, the ancestral cultivars and the varietal diversification process through time and space are not well known.

In spite of the important corpus of bio-archaeological, morphological, historical and genetic data available, the identity of former cultivars, history, biogeography and mechanisms of grapevine domestication remain obscure.Morphological criteria for the identification of archaeological remains (seeds and wood) attributed to *Vitis vinifera* are highly incomplete, and those ancient texts mentioning various cultivated grapevines are not exploitable to characterize ancient varieties.

In the present state of research, in France and elsewhere, studies on seeds are still too limited to allow a precise discrimination between wild and cultivated grapes [41].Although

informative, the main limits of these former studies concern the absence or the inadequacy of modern reference collections on which they are based. In every case, they represent local or regional studies and concern a reduced number of cultivars and wild specimens.The present study is based on the geometrical analysis of grape seed structure. It aims to test shape criteria in order to discriminate between wild forms and modern cultivars, interpret changes that have occurred during domestication, quantify the phenotypic diversity in the wild and the cultivated compartments and interpret shape diversity in relation to the supposed geographical origin (country or region) and parentage evidenced by genetic approaches.

Although the analysis of genetic diversity based on living material is very successfulon the first analyses based on ancient DNA, using a few microsatellite markers, though encouraging, have not yet provided significant results for the identification of ancient grapes. Shape characterization of cultivated varieties combined with genetic data should allow a better understanding of the changes that have occurred during domestication and finally identification of ancestral forms of current cultivars, based on the analysis of archaeological grape seeds.

Conclusion

The grapevine (*Vitis vinifera*) belongs to the family Vitaceae, which comprises about 60 inter-fertile wild *Vitis* species distributed in Asia, North America and Europe under subtropical, Mediterranean and continental–temperate climatic conditions. It is the single *Vitis* species that acquired significant economic interest over time; some other species, for example the North American *V. rupestris*, *V. riparia* or *V. berlandieri*, are used as breeding rootstock due to their resistance against grapevine pathogens, such as *Phylloxera*, *Oidium* and mildews.

Indeed, a great majority of cultivars widely cultivated for fruit, juice and mainly for wine, classified as *Vitis vinifera* L. subsp. *vinifera* (or *sativa*), derive from wild forms [*Vitis vinifera* L. subsp. *sylvestris* (Gmelin) Hegi]Grape seed extract possess lots of medicinal value[11-12]. Brine shrimp lethality assay is an economical and cost effective method for investigating the cytotoxic activity[13]. Hence from the results it can be concluded that grape seed is a promising candidate against brine shrimp and potents cytotoxic activity.

Abstract

Introduction: Carabelli's trait occurs on the palatal surface of the mesiopalatal cusp of permanent upper molars and deciduous upper second molars. The distribution of the carabelli trait is highly variable in different regions and races of the world. The trait is entirely absent in some individuals, while present in others, in a variety of forms. To determine the prevalence of carabelli trait in a group of people visiting saveetha dental college.

Materials and Methods: In this descriptive study, 200 maxillary molars were examined. Examination of maxillary molars was done by direct intra oral examination. Morphological details of the maxillary molar crown, gender of the subjects were recorded and Dahlberg classification was used. Photographs were taken.

Results: The prevalence of the trait was 76.5%, with significantly different distribution between males and females. Class 5 was the most frequent configuration (17%) and Class 7 was the least frequent(2%). The prevalence of carabelli trait is seen more in first maxillary molars than second maxillary molars.

Conclusion: The incidence of cusp of carabelli is lower compared to the European studies, showing a frequency of 76.5% with Class 5 (small tubercle) being more prominent and Class 7 being less prominent and more prevalence of bilateral symmetry and a bit of male prediction.

KeyWords*: Carabelli trait, Dahlberg classification, Prevalence, Maxillary molars, Cusp of carabelli*

Introduction

Teeth are an excellent object for the study of human variation and are used to address questions in numerous disciplines including anthropology. Morphological features of teeth are controlled to a greater extent by genes than skeletal features. In contrast to bone, hard dental tissues do not remodel once they have formed. Consequently, tooth morphology changes through life only as a result of pathological (e.g. caries, resorption, trauma) and age-dependent processes (e.g. attrition, abrasion). Teeth are very resistant to post-mortem degradation and to mechanical trauma. So they are generally better preserved than bones in archaeologically derived human remains. An additional advantage of teeth is that their morphological features are observable on extracted specimens, on specimens from skeletal-dental remains, on dental impressions or cast reproductions, and directly in the mouth of a living person. Tooth morphology has been known to show variation from one ethnic group to another. One such morphological characteristic which has warranted a lot of investigations in different ethnic groups of the world is the trait of Carabelli [1]. George carabelli in 1842 first described a tubercle on the lingual surface of the mesiolingual cusp of maxillary molars. This protuberance goes by other denominations like an accessory cusp, a fifth lobe, a supplemental elevation, a fifth cusp, molartubercle, carabelli's cusp, a carabelli's anomaly and a carabelli's tubercle [2]. The phenotypical appearance of the trait is attributed to a dominant Mendelian gene and also to the intake of fluorides, nutrients and the size of the jaws. Therefore, it s a result of interaction between genetic and environmental factors [3]. Carabelli cusp is expressed in several degrees and different frequencies between different populations. The variation of molar tubercle is significant in the diagnosis of carious lesion and in cases of anthropological studies and those related to forensic dentistry [4]. The aim of this study is to evaluate the prevalence and symmetrical trait of carabelli in permanent dentition of individuals visiting saveetha dental college.

Materials and Methods

Patients, who came for treatment to Saveetha Dental College, were examined for this study. After obtaining permission from the institutional research committee, the study was carried out for a period of 4 months from February 2015 to may 2015. Healthy permanent maxillary molars, devoid of dental caries and attrition found during intra oral examination of the patients were

considered in this study. The required consent and assent from the patients were obtained and those willing to participate in this study were included. During the study period, 200 permanent maxillary molars were examined of age group from 20 years old to 40 years old people. On intra oral examination, symmetrical appearance of carabelli trait and prevalence of carabelli trait in first permanent maxillary molars and second permanent maxillary molars were recorded. Prevalence of carabelli trait in maxillary first molars and maxillary second molars, according to gender was also recorded. Dahlberg's classification [5] was also used for the determination of degree and expression of carabelli trait.

Results

In this study, 76.5% of the maxillary molars examined have shown the carabelli trait. Out of 200 maxillary molars examined in this study, 132 were first maxillary molars and 68 were second maxillary molars. The carabelli trait is more in maxillary first molars (93.9%) than maxillary second molars (42.6%). [Table 1] Bilateral symmetry (76%) of carabelli trait is more than unilateral symmetry (24%) among the examined individuals. [Table 2]. On using Dahlberg's classification for determining the degree and expression of carabelli cusps, Class 5 is the most common configuration (23.5%) and Class 7 is the most least configuration (1%). [Table 3] Out of 200 maxillary molars examined, 130 were from male individuals and remaining 70 from female individual. Based on gender predilection, the incidence of carabelli trait is bit higher in males (80%) than females (70%). [Table 4].

Table 1: Prevalence of carabelli trait in first and second maxillary molars

	FREQUENCY	PERCENTAGE
Maxillary first molars	124/132	93.9%
Maxillary second molars	29/68	42.6%
TOTAL	153/200	76.5%

Table 2: Prevalence of symmetrical trait of carabelli

SYMMETRY	FREQUENCY	PERCENTAGE
Bilateral symmetry	152	76%
Unilateral symmetry	48	24%
Total	200	100%

Table 3: Dahlberg's scale for the determination of degree and expression of the carabelli trait

-

DAHLBERG'S SCALE	FREQUENCY	PERCENTAGE
0	47	23.5%
1	10	5%
2	25	12.5%
3	12	6%
4	29	14.5%
5	48	24%
6	27	13.5%
7	2	1%
TOTAL	200	100%

Table 4: Presence of carabelli trait based on gender predilection

	PRESENCE	ABSENCE	TOTAL
MALES	104 (80%)	26	130 (65%)

Limitations

This study was not without any limitations. Sample size was small compared to other studies done related to cusp of carabelli or molar tubercle in maxillary molars. Furthermore, the participants were selected from only one institute and the age group of the participants is limited, making generalization of the results difficult. Cross-sectional nature of the study and absence of any control groups might not have served our purpose of assessing the attitude and ascertaining the importance of undergraduate education in Psychiatry. Some observed differences on group wise and sex-wise comparison may be attributed solely to the cohort effect.

Discussion

Carabelli's trait occurs on the palatal surface of the mesiopalatal cusp of permanent upper molars and deciduous upper second molars. It is a quasi continuous variable, i.e. it can be either present or absent, but when present, it exhibits continuous variation in expression. The expression of the

trait varies from a slight or distinct single furrow, pit, double furrow, y-shaped furrow, or slight protuberance lacking a free apex, to a small, moderate or large cusp, which occasionally equals in size the main occlusal cusp. A pit and a furrow - single, double, y-shaped are negative expressions of the trait, whereas a protuberance and a cusp are its positive expressions. The frequency of the carabelli trait varies from population to population or within the population groups [6], [7]. The cusp of carabelli has never been reported to interfere with occlusion, no matter how large it is, but, has a great potential for the development of tooth decay. The cusp expression has a tubercle in addition to the groove; this tubercle may act as a physical barrier against the cleansing mechanisms of a tooth brush and physiological cleaning by the tongue movement and the salivary flow. In cases where the carabelli trait was absent, caries was not detected which supports the idea that the carabelli structure presents a foci for plaque accumulation and caries development. The method by which caries was examined, i.e., avoiding apically directed force, might have contributed to the low caries prevalence [8], [9], [10].

The presence of the carabelli trait might be due to both genetic and environmental factors [11]. There is still a controversy in the literature with regards the degree of genetic control in the prevalence and expression of this trait. While a field theory suggests that the trait is induced, and therefore, is subjected to environmental stress, clonal model theory suggests that the trait is intrinsic, and therefore, it would be less responsive to environmental factors [12]. Being a distinguishing feature or characteristic of an individual, carabelli trait is frequently used in anthropological, clinical and forensic studies [13]. The significance of carabelli cusp for evolutionary biology is that it provides a well-documented glimpse at the origin of a new cusp. Over the evolutionary history of mammals, which has experienced a large-scale increase in dental complexity, major dental traits have evolved that began at early evolutionary stages as peripheral features, low on a tooth crown, and developed presumably late in ontogeny. Transforming a small, low peripheral cusp into a centrally located, large cusp must be accomplished by shifting the initiation of that cusp earlier in ontogeny. However, origin of a new cusp in the first place, to use carabelli expression as a model, can occur as a byproduct of natural variation in the spacing of enamel knots and offset of morphogenesis, which impacts inter cusp spacing and tooth size. It is rarely possible to study population level variation in the early evolutionary stages of the origin of a new cusp in extinct species.

The findings of the present study showed an overall prevalence of 76.5% in the surveyed group, with Class 5 (23.5%) being more prominent and Class 7 (1%) being less prominent. Based on the previous studies of carabelli trait on racial basis, it is proved that, the Mongoloids had a low prevalence whereas Caucasians had a high prevalence [14], [15]. Among the Caucasians, Asiatic population showed a lower trait, whereas, European population showed higher trait with a prevalence of 96.6% with class 6 predominance [16], [17]. When the trait symmetry is considered, bilateral symmetry (76%) is more predominant than unilateral symmetry (24%) and the prevalence of carabelli trait is more in maxillary first molars (93.9%) than maxillary second molars(42.6%). Bilateralism of the trait, in this study, was very high. This supports the findings of other researchers [18],[19], which they agree that bilateralism of the trait is more frequent. The presence of the trait can't be used as a sole criterion for identification of maxillary molars as it is also found to occur in maxillary second molars. In this study, a bit of higher prevalence is seen in males (80%) than females (70%), which may be due to the reduction of crown size in females. Many studies [20], [21], [22], [23] failed to show any sex dimorphism in the occurrence of the trait, although some investigators [24], [25] observed a sex-linked pattern. Thus, it is verified that the sexual dimorphism related to the molar tubercle changes among the different studies and populations.

Conclusion

The incidence of cusp of carabelli is lower compared to the European studies, showing a frequency of 76.5% with Class 5 (small tubercle) being more prominent and Class 7 being less prominent and more prevalence of bilateral symmetry and a bit of male prediction. Dentists are advised to perform a careful examination to the palatal surfaces of the maxillary first and second molars to rule out the presence of the cusp of carabelli, as they are way more prone to plaque accumulation, which in turn can lead to development of dental caries. Future studies should be made to assess the relationship of the carabelli trait to genetics and its heritability.

Saveetha University, Chennai, India

Abstract

Background: The mandibular third molar is an unusual tooth in the oral cavity. The angulation and position keeps changing as the tooth erupts. The orthodontist need to be aware of the relationship of the mandibular third molars to the remaining teeth in the dental arch, as it can cause complications like impaction, mandibular anterior crowding. Thus theaim and objective of this study is to analyse the changes in mandibular third molar angulation, pre and post orthodontic treatment and also to evaluate the positional changes of the mandibular 3rd molars.

Materials and Method: The study was a cross sectional analytical study and data was retrospectively retrieved from archival records of patients visiting Saveetha dental college for orthodontic treatment. Pre and post Lateral cephalograms and orthopantomograph records of 20 orthodontic patients were selected. The mean age of the patients ranged from 20-35 years and all the cases had undergone extraction of mandibular first premolars for the orthodontic treatment. The angulation of the mandibular third molars was measured using OPG and the positional change was measured with lateralcephalograms after tracing the radiographs.

Result:A significant change in mandibular third molar angulation was observed on both right (10.4º) and left sides (13.3º) of the mandible, pre and post orthodontic treatment and positional change of1.04 and 1.31 cm was observed pre and post orthodontic treatment.

Conclusion: The present study suggests that premolar extraction therapy has a favourable effect on third molar angulation.

Keywords: *third molar, pre and post orthodontic, lateral cephalograms, orthopantamographs, impaction*

Introduction

Mandibular third molar is an atypical tooth, due to its variability in formation, variations in crown and tooth morphology and most posterior location in the jaw. Varies studies have been done on differences in presence or absence of the tooth, variations in morphology and size. But recent studies concentrate more on the calcification, position and angulation of mandibular third molars.

Mandibular third molar calcification begins at 8 to 10 years of age and root formation starts at the age of 15 and the tooth erupts between 17 to 30 years of age. Of all the teeth present in the oral cavity, third molar eruption presents the most complications. They are often impacted or retained or embedded, which can cause conditions such as pericoronitis (inflammationofpericoronal flap covering the coronal aspect of a developing tooth), cavities due to difficulty in brushing as it is in the posterior most location, root resorptions, alveolar bone loss leading food impaction and periodontitis, cystic processes (eg. dentigerous cysts most commonly associated with impacted third molars), or tumours.

Insufficient space in jaw leads to more distal eruption of third molars rather than erupting in its normal location. The difference in morphology like root curvature will also lead to displacement of the tooth.

When drawing orthodontic treatment plan, sometimes the mandibular third molars are ignored, as it is always assumed that, the tooth will be impacted and will be indicated for extraction. But as a dentist, the key treatment objective is to conserve all dental organs and to maintain maximum masticatory function. Nevertheless, it has been estimated that 54% of mandibular third molars are removed prophylactically, even though they do not present any subjective symptoms

The development of third molars, their influence on the dental arches and its eruption potential is an important consideration for both the dentist and the orthodontist when planning active treatment plan and long-term maintenance [1].The impaction of mandibular third molar is the most common problem [2].Approximately 43% of mandibular third molar

impactions may be classified as mesial impactions while maxillary third molars are mostly distally impacted [3]. The mandibular third molar tooth buds begin their formation at approximately 8 to 9 years of age and also show a great variation in in size, position, shape, root shape, and development time [4,5,6,7].One explanation for the third molar impaction is inadequate retro molar space due to limited resorption at the anterior aspect of the mandibular ramus [8,9,10,11].

The orthodontist need to be aware of the relationship of the mandibular third molars to the remaining teeth in the dental arch. The main aspects to be analysed are whether the third molars will erupt or become impacted, whether they will cause crowding of the mandibular anterior teeth, and whether the extraction of other teeth will prevent crowding and influence their eruption [12].Developing third molars continually change their angular positions and undergo important pre-eruptive rotational movements [11, 13,14].The causes for mandibular third molar impaction and prediction of its eruption have also been studied extensively. In contrast, the effect of orthodontic treatment on the developing third molars has not been subjected too much investigation. The purpose of this study is evaluate the change in the angulation of mandibular third molars pre and post orthodontic treatment andalso to evaluate the positional changes of the mandibular third molars with reference to the occlusal plane.

Materials and Method

The study was a cross sectional analytical study.Dental records of patients who had undergone fixed orthodontic treatment at the Department of Orthodontics, Saveetha Dental College and Hospital, Chennai, India, were obtained from the year 2014 to 2016. Out of 600 records collected, 20 records were randomly selected with inclusion criteria as meanagefrom 20-35 years,had undergone extraction of mandibular first premolars for the purpose of orthodontic treatment, and absence of any congenitally missing right and left mandibular third molars, with pre-treatment (T1) and post treatment (T2) Lateral cephalogramsand panoramic radiographs (orthopanmographs). Rest 580 records were excluded from the study. Tracing of pre and post treatment lateral cephalograms and orthopantamograms were done on a tracing paper. The angulation of the mandibular third molars was measured by tracingOPG with lines drawn from the midpoint of the ramus of the mandible as the horizontal reference point and long axis of the tooth as vertical reference point and compared with pre and post treatment radiograph for both right and left mandibular third molar. The positional change of the right and left mandibular 3rd molar was measured and compared using pre-treatment and

post treatment lateral cephalograms, with a line drawn from the anterior most part of the ramus of the mandible tothe mesial cusp tip of 3rd molar.The measurements were recorded and tabulated and was subjected to statistical analysis to find the mean difference in angulation and mean difference in position of the mandibular third molars on both right and left side of the jaw.

Results

The mean angular changes in mandibular third molars, pre andpost orthodontic treatment are depicted in table1. A mean difference of 10.4^0 and 13.3^0 was found in right and left mandibular third molars respectively. Graph 1 represents the right side angular changes of third molar seen in all the samples, while graph 2 represents the changes seen in left side of mandible.Table 2 represents mean positional changes of mandibular 3rd molar estimated from lateral cephalograms. The positional changes of mandibular third molars taking place before treatment was found to be 1.04cmand after orthodontic treatment it was found to be1.31cm and is represented in graph 3.

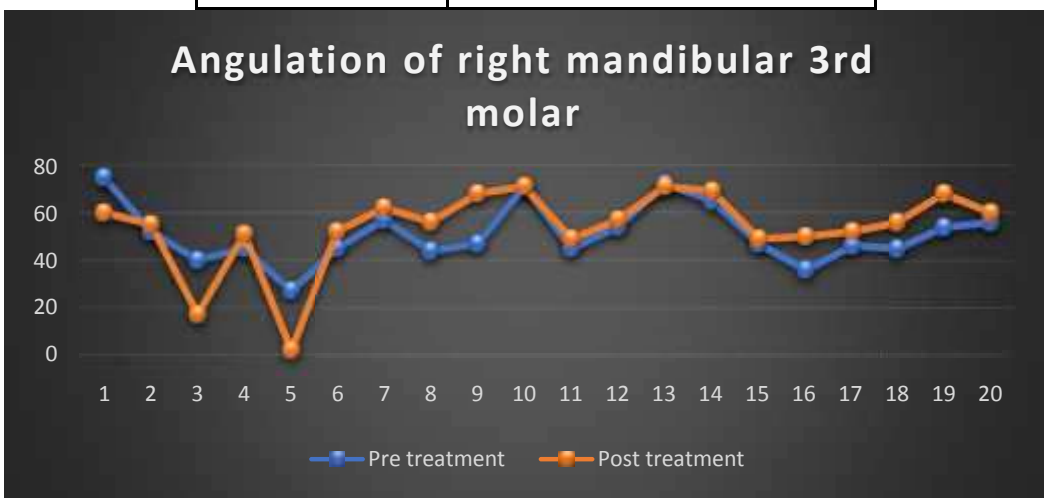
Table 1: Mean Angular changes pre and post orthodontic treatment (in degrees)

	Pre treatment	Post treatment	Mean Difference in angulation(in degrees)
Right mandibular 3rd molar	46.7	57.1	10.4
Left mandibular 3rd molar	43.7	51.3	13.3

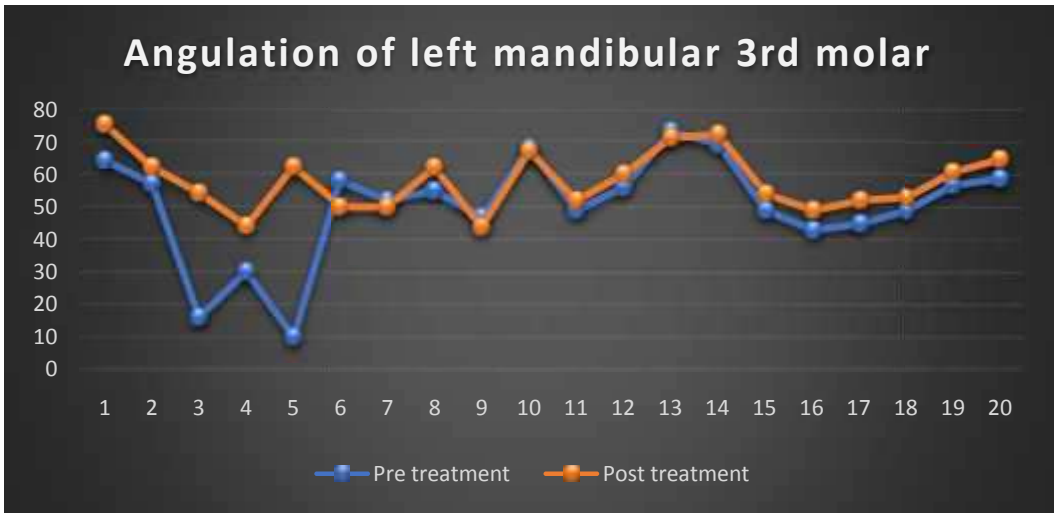
Table 2: Mean positional change of mandibular third molars in lateral cephalograms pre and post orthodontic treatment (in cms)

	Mean Distance (in cms)
Pre treatment	1.04

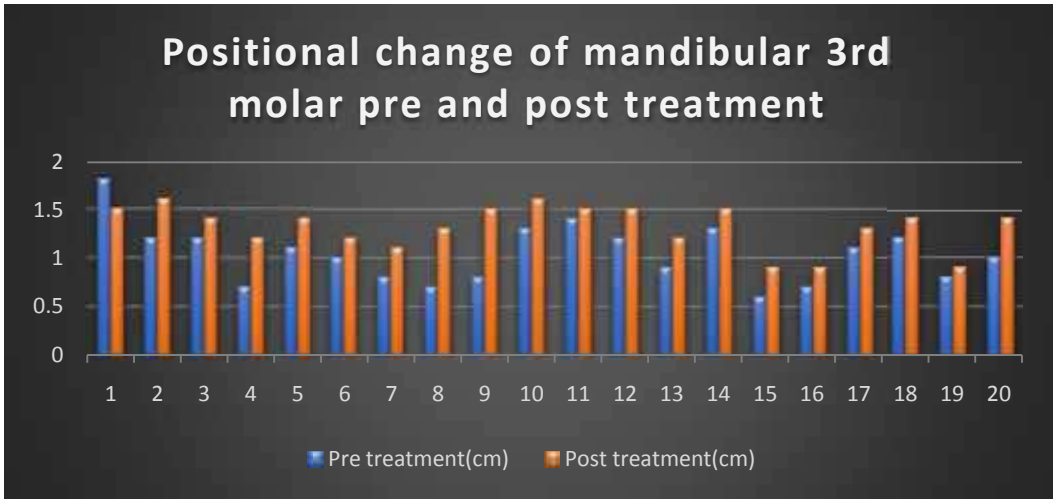
Post treatment	1.31



Graph 1: Right side angular changes of third molar pre and post orthodontic treatment (in degrees)



Graph 2: Left side angular changes of third molarpre and post orthodontic treatment(in degrees)



Graph 3: Positional changes of mandibular 3rd molarspre and post orthodontic treatment (in cms)

Discussion

Third molar impaction is a major clinical problem and if its eruption can be predicted at an early age during the course of the orthodontic treatment, then the occurrences of difficult impactionscan be avoided. In the study, a significant change in mandibular third molar angulation is seen on both right (10.4) and left sides (13.3) of the mandible, pre and post orthodontic treatment. Previous studies have used the occlusal plane and mandibular plane as the horizontal plane of reference to measure the angular changes of 3rdmolar. However, the changes in the occlusal plane, with treatment and modelling of the lower border of the mandible during growth may cause misinterpretations of third molar angulation [15].Measurements of third molar angulation on lateral cephalograms may be biased because of differences in angulation between the superimposed images [16].

Richardson has proved that measurement of third molar angulation on lateral cephalograms may be biased and can only be overcome if measurements are made on 60 degree head films of right and left sides [13, 14]. Studies have shown that panoramic radiographs are reliable tool for evaluation of angular changes and hence they were used in the present study. It also showed that there was not much significant difference in angulation in right and left mandibular third molars.

The findings of the present study also suggests that premolar extraction therapy has a favourable effect on third molar angulation. The mechanism may be that mesial movement of first molar, associated with extraction site closure,promotes mesial tipping of the third molar

bud.Elsey and Rock have stated that the closure of mandibular extraction sites commonly allows improvement in the position of unerupted third molars. [17, 18, 19]

Conclusion

Impaction or failure of mandibular third molars to erupt is mostly due to lack of space in the alveolar arch between the distal of the second molar and the ascending ramus, most posterior location, aberrant anatomy and abnormal eruption pattern, due to which extraction remains the treatment of choice. Contemporary dental practice aims at minimal intervention and retaining every functional component of dental arch. Orthodontic treatment mostly requires extraction of premolars for the required space management [20, 21].This, can be useful for movement of third molar mesially for normal eruption. This study aimed at estimating movement of third molar post orthodontic treatment.

The study reveals that:

- A change in angulation of third molar by 10.4^0 is seen on the right side and 13.3^0 is seen on right side of mandibular third molar.
- If there is a mesio angular impaction of $<10^0$ before the start of the orthodontic treatment, then there is a high chance that the tooth would get upright automatically by the time the orthodontic treatment is done.

Hence, post – orthodontic treatment can be useful for movement of third molar into eruption. Further studies can be done to orthodontically move third molar into functional occlusion.

Abstract

Introduction: In modern populations, the impaction rate is higher for third molars than for any other tooth. Mesial movement if present it can sometimes unlock a mild mesioangular impaction of third molar so it is reported to analyse whether there is any change in the second molar angulation and if so what is the average change in the angulation following first premolar extraction

Material and Methods: 58 patients who have undergone all four extractions werectaken. Pre-treatment and immediate post treatment record of the patients was traced. The armamentarium used for this research are orthopantomograms, panorex machine,Tracing sheets, 30cm scale, pencil, eraser, protractor.

Result: The average pre treatment angle is 64.24 and the average post treatment angle is 62.40. So the change in angle is shown to be 2 degree.

Conclusion: In cases such as bimaxillary protrusion and class II malocclusion all four extraction has become inevitable. Drifting of the adjacent tooth is common in such cases. Due to the recent advancement in anchorage system like TAD helps to overcome the anchorage loss. Sometimes angulations of second molar helps to unlock a mild mesioangular impaction of third molar

Key Words: *Premolar extraction, angulation, second molar, anchor loss, first Premolar*

Introduction

The most common malocclusion encountered by a orthodontist in Indian patients is bimaxillary protrusion and class IImalocclusion. The commonest treatment plan for these patients would be extraction of all first premolars. The most preferable anchorage unit in these cases is the is the first molar. A maximum anchorage or group an anchorage is preferred in these cases while extracting all the first premolars the most common side effect is anchorage loss. It is a reactionary effect of space closure following the first premolars extraction in orthodontic treatment. While taking the molars as anchorage unit with maximum anchorage75% of retraction takes place by anterior teeth and the remaining 25 % takes place due to posterior protraction. When there is a posterior protraction the molars may have mesial migration. There are various research and studies regarding the anchor loss and mesial migration of first molars due to first Premolar extraction however not many studies have been done in terms of measuring the angulation changes in second molar . The development of third molars and its influence on the dental arches has been a major concern to the dental profession [1]. Mandibular third molar impaction is a major issue in modern dentistry. [2] The path of development of third molars in human beings is not regular and the formation, calcification timing, and the position and course of eruption of these teeth show variability. Often, third molars are impacted or congenitally missing. [3]In modern populations, the impaction rate is higher for third molars than for any other tooth. [4] Mesial movement if present it can sometimes unlock a mild mesioangular impaction of third molar so it is reported to analyse whether there is any change in the second molar angulation and if so what is the average change in the angulation following first premolar extraction

Inclusion

Orthodontic patients treated with all four extractions

Retraction performed with regular friction mechanics

Patients with the presence of second molar in normal position.

Exclusion

Cases with friction less mechanism and micro implants aided retraction

Patients with immediate post treatment records not available

Patients with Temperomandibular disorder

Material and Method

Case records of 58 patients who have undergone all four extractions were taken. Pre-treatment and immediate post treatment record of the patients was traced. The line joining the midpoint of right and left rami is taken as the reference point (XI point). The angle which the long axis of the second molar makes with this reference plane in pre-treatment and post treatment radiographs is recorded.The difference between the pre treatment and the post treatment angulations gives the change in angulation of the second molar.

The armamentarium used for this research are orthopantomograms, panorex machine ,Tracing sheets, 30cm scale, pencil, eraser, protractor(figure 1)

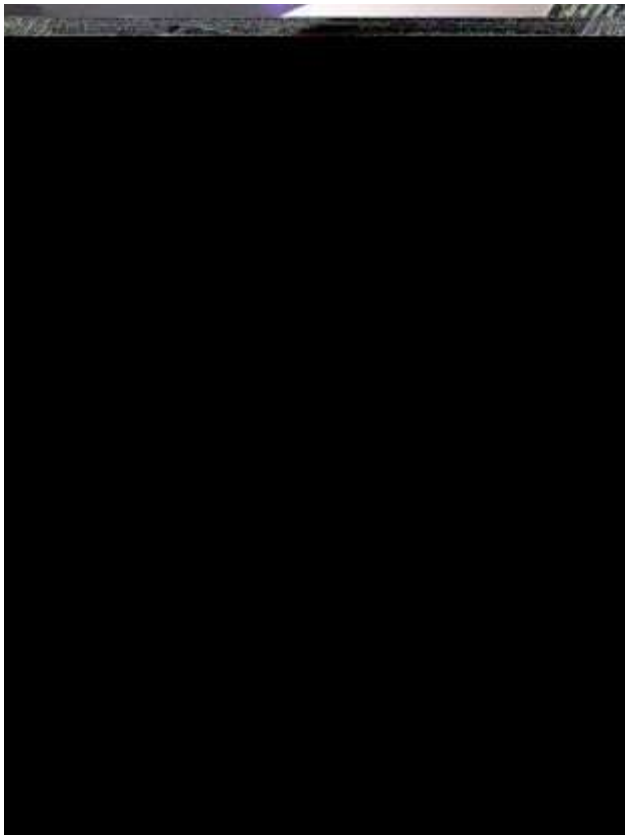

Figure 1: Panorex machine was used for taking orthopantomograms for the study.

Figure 2: Tracing sheets, metal scale 30cm, pencil , eraser , sharpener ,protractor .

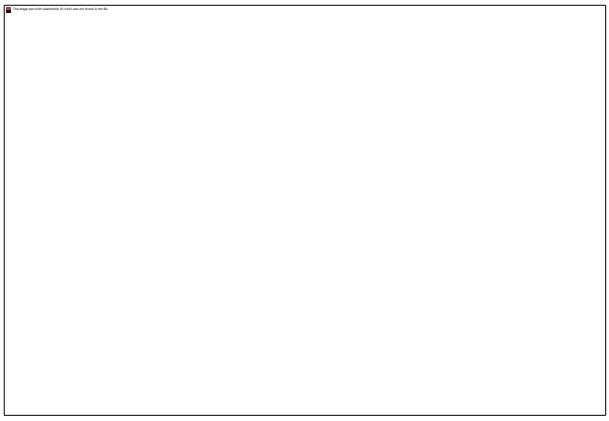

Figure 3: Tracing of the orthopantomogram done in a tracing sheet. The line joining the midpoint of right and left rami is taken as the reference point (XI point) . The angle which the long axis of the second molar makes with this reference plane in pre-treatment and post treatment radiographs is recorded.

Result

This study included Case records of 58 patients who have undergone all four extractions were taken. Pre-treatment and immediate post treatment record of the patients was traced. Orthodontic patients treated with all four extractions, Retraction performed with regular friction mechanics, Patients with the presence of second molar in normal position were included in the study. Patient with Cases with friction less mechanism and micro implants

aided retraction, Patients with immediate post treatment records not available, Patients with Temperomandibular disorder were exculded from the study. The data obtained from the study was statistically analysed using paired t test. In this research it has been considered that if the pre operative angle is greater than post operative angle then the change in angulations is considered as positive. If post operative angle is greater than preoperative angle then the change in angulation is considered as negative. Out of 58 cases 41 cases have shown positive results while the rest 17 has shown negative results. It has been concluded that 70.68% 0f cases shows greater pre operative angle than post operative angle the rest 29.31% of cases shows greater post operative angle than pre operative angle. The average pre treatment angle is 64.24 and the average post treatment angle is 62.40. So the change in angle is shown to be 2. This shows the mesial tilt of 2 degree.

(If P-Value < 0.05 then statistically Significant)

Table: 1 Paired T-Test to compare pre and post mean values

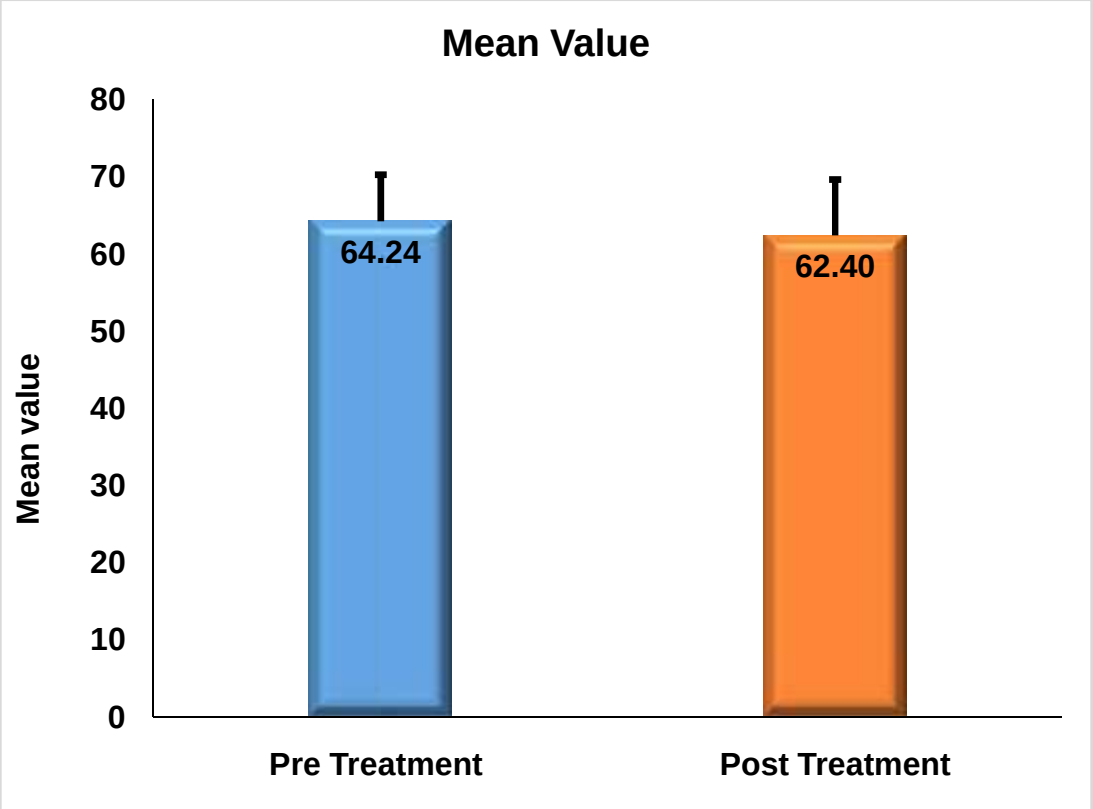
	N	Mean	Std. Dev	t-Value	P-Value
Pre Value	58	64.24	6.039	2.047	0.045
Post value	58	62.40	7.235		

Table: 2 One sample T-Test to compare mean differences (from "0") for positive and negative differences

Differences (Pre – Post)	N	Mean	Std. Dev	t-Value	P-Value
Positive (Pre > Post)	41	5.37	4.476	7.675	<0.001
Negative (Pre < Post)	17	-6.65	3.061	8.954	<0.001

In our study the P Value is less than 0.001 hence our study is statistically significant.

Graph: 1 Showing the mean value of pre treatment and post treatment values



Discussion

The purpose of this study is to analyse the change in the angulation of lower second molar after the extraction of lower first Premolar. This study shows mesial movement of second molars up to 2 degrees in all four extraction. Anchorage loss is the reactionary effect of space closure after the extraction of premolars .It is generally accepted that a strong relationship exists between root surface area and anchorage potential, the choice of teeth to be extracted should have a direct influence on the amount of anterior segment retraction .Anchorage is the resistance to unwanted tooth movement. [5, 6]. Major concern while correcting severe

crowding, excessive over jet, and bimaxillary protrusion is control of Anchor loss. Stability following orthodontic treatment continues to be a challenge to all orthodontists [3, 4]the ability to maintain long-term alignment following orthodontic treatment involving the extraction of premolars has unfortunately also been unpredictable. [7]

The role of extractions in the treatment of orthodontics is being a controversy in the history This controversy exists even today and, the extraction decision is still the most critical decision made by orthodontists during treatment planning .This is complicated further by the fact that the relative efficacy of extraction or non extraction strategies, in either the short or long term, has yet to be fully established.

Various studies have documented that premolars are the most commonly extracted teeth for orthodontic treatment located between the anterior and posterior segments of teeth premolar extractions seems to allow a straightforward relief of crowding or the correction of interincisor relationship. It has been suggested that improvements in techniques for controlling the tooth movement in dimensions and improvements in the correlation of these movements with anticipated facial growth changes have both increased the number of extraction options.

Different authors, for various reasons, have suggested variations in extraction sequences, including maxillary and mandibular first and/or second premolars. Its accepted that, during the treatment involving the extraction of teeth, dimensional changes in arch occur and these dimensions changes continue following active treatment. Furthermore, the ability for extraction spaces in the maxillary arch to be used in a predictable fashion has not yet been widely stated in the literature. In one such study, Williams and Hosila24 found that, in cases involving the extraction of 4 first premolars, approximately 66.5% of the available extraction space was taken up by the retraction of the anterior segment. In cases involving extractions of maxillary first and mandibular second premolars, 56.3% of the available extraction space was taken up by the retraction of the anterior segment.

It is generally accepted that a strong relationship exists between root surface area and anchorage potential, the choice of teeth to be extracted should have a direct influence on the amount of anterior segment retraction. For instance, Creek more stated, as a rule-of-thumb, that when first premolars are extracted, one can expect the posterior teeth to move forward

approximately one-third of the space, leaving two-thirds of the space for the relief of crowding and incisor retraction. When second premolars are extracted, one can expect the posterior teeth to move forward approximately half the extraction space, leaving the remaining half for the relief of crowding and the retraction of anterior teeth.

The concept of physiology drift commonly referred to as 'driftodontics'. It is been gaining acceptance orthodontic community after the Premolar extraction. The accurate drift and change in the inclination of the adjacent tooth has not be adequately documented. This study is done to evaluate the amount of inclination of the second molars that takes place after he extraction of first Premolar. Study done by Christos Livasa stated that Orthodontic treatment with unilateral maxillary M1 extraction resulted in a significant increase in the mesial inclination of maxillary second [8]. Similarly study done by D. M. Swessi C. D. Stephens stated that teeth tended to tip towards the extraction space, the amount of tipping was small (not exceeding 15 degrees in the majority of cases). The tipping was found to be greatest during the first 6 months [9]

In this study orthopantomograms of 58 patients were traced. The pre operative and post operative orthopantomograms were traced separately. The study included Orthodontic patients treated with all four extractions ,retraction performed with regular friction mechanics, Patients with the presence of second molar in normal position and patient with temperomandibular disorder were excluded from the study . Reference plane and reference angle were marked .The midpoint of right and left rami was connected by a line this is considered as the reference point. The angle formed by the long axis of the second molar makes with this reference plane in pre-treatment and post-treatment. These reference angle was measured from the pre operative and post operative radiograph . These values are then statistically analysed using paired t test . In this study the change in the angle between pre and the post treatment is around 2 degree with a standard deviation of 1 which is statistically significant.

A study done by Tarvade SMT has concluded that the difference in the mean and standard deviation between pre and post treatment is found to be 3.11which shows improvement in the angulation which had a distal tilt which was not statistically significant [10] Similarly a study done by a Avinash Gohilot, Tejashri Pradhan , Kanhoba Mahabaleshwar keluskar show an improvement in the angulation around 0.6 degree this shows a distal tilt.[11]Another study

done by Suruchi Jain , Ashima valiathan they show a difference in angulation around 6 degree which also shows a distal tilt [12-16]Study done by Luz Victoria showed that Verticalization of the third molar in the group of female subjects, represented by the α angle (.033), and the β angle (.016) on the left side.[17]In men, unlike women, third molar angulation showed an increase to mesial inclination; changes to the α angle were significant on the right side (.030). Study done by Tae-Min-You on effect of Effect of premolar extraction and presence of the lower third molar on lower second molar angulation in orthodontic treatmentshows . The angular difference and ratio of M2 to M1, the angulation change of M2 between pre- and postorthodontic treatment, and the distal bone level of M2 were higher in the nonextraction group than in the control and extraction groups[18]. Study done by Huda shows significant improvement in the third molars angulation in the extraction orthodontic therapy group compared to non- extraction group, when compared to the previous study this study shows greater angulation of lower second molar[19].Orthodontic treatment with premolars extraction during third molar development, and subsequent improvement of its angulation and path of eruption still remain controversy in previous literatures. [20]

does the extraction therapy has an impact on the eruption of my wisdom teeth is often asked by orthodontic patients to the orthodontist . In general this situation is uncertain among orthodontists, and in most of the cases, we have very few data on whether the extraction of premolars has beneficial effect on the eruption of third molars.

Third molars exhibit variation in their size, shape, position, root formation, time of development, and path of eruption. [21] The prevalence of impaction of at least one impacted lower third molar has been reported as 72.7% in a cohort aged 20–30 years. [22] Today, third molar impaction has been reported as the mostcommon of all tooth impactions.[23] In addition excessive interproximal attrition allowed mesial drift of the posterior teeth which made the incidence of third molar impaction relatively low.[24, 25]

The mandibular third molar is the most frequently impacted tooth after the maxillary third molar. For the lack of space between the second molar and the ramus has long been a major etiologic factor of mandible third molar impaction.[26-28] Björk et al. stated that the alveolar arch space behind the second molar is deficient in 90% of mandibular third molar impaction cases.[29] In their study, they examined 243 cases to investigate the correlation between mandibular third molar impaction and some cephalometric parameters. They reported that factors that affect the space of third molars were mandibular length, backward direction of eruption of the dentition, and vertical direction of condylar growth, which were associated

with the degree of resorption on the anterior aspect of the mandibular ramus.Mesial movement of second molars up to 2 degrees in all four extractions. Premolar extractions had a positive influence on the second molar angulations both on right and left .

Increased use of readjusted appliances, have replaced closing loop arches to various forms of sliding mechanics Sliding mechanics have great advantages , such as minimal wire-bending time and adequate space for activations.[30]

The retraction of four incisors post canine retraction is accepted as a method to reduce the mesial movement of the posterior teeth segment, whereas complete retraction of six anterior teeth may create anchorage problems. Added to this the tipping action built into anterior brackets in readjusted appliances may produce problems of anchorage. These problems may be adjusted by the use of a transpalatal bar and extra oral appliances.[31] However, intraoral anchorage devices provide unacceptable anchorage, whereas extraoral appliances provide a suitable anchorage but they are completely dependent on patient compliance.

Skeletal anchorage using dental implants,[33-34]manipulates,[35] miniscrews, [36] and micro screws[37-39] provides a complete anchorage for tooth movement. Miniscrew or micro screw implants are easy to place and remove and economical. Most importantly, because of their reduced size, they can be placed in the intra-arch alveolar bone without any damage to tooth roots. Added to this in contrast to dental implants orthodontic force applications can begin immediately after placement, . Therefore, these advantages have expanded the use of mini- or microscrew implants for various orthodontic problems.

By using microscrew implants in the mechanics of complete retraction of six anterior teeth, time required for the treatment can be reduced effectively and clinicians can move teeth to satisfy the treatment goal without patient compliance for anchorage devices.

Conclusion

In cases such as bimaxillary protrusion and class II malocclusion all four extraction has become inevitable . Drifting of the adjacent tooth is common in such cases .Due to the recent advancement in anchorage system like TAD helps to overcome the anchorage loss .Sometimesangulation of second molar helps to unlock a mild mesioangular impaction of third molar further study is required with larger number of samples to analyse the changes that happens to the second molar after the Premolar extraction.

Abstract

Introduction : infectious diseases and foreign bodies. Sudden decrease and increase in their count causes marked change in the immune system.The present study aims to highlight the total and differential leukocyte Leukocytes are known as cells of immune system that are involved in protecting the body against both count in post therapeutic cancer patients

Materials and Method:A sum of 15 blood smears were made from peripheral blood of post therapeutic cancer patients in Saveetha Dental College and staining was done to determine the total and differential leukocyte count using leishman's stain.

Result: The total and differential count varied significantly in few post operative patients and few had various diseases like lymphocytosis, neutrophilia, neutropenia and eosinophilia.

Conclusion: All smears showed hypersegmentation and hypergranulation due to depletion of vitamin B_{12} and folic acid through radiation and surgery.

Key Words: *Hypersegmentation, Hypergranulation, Leukocytosis,Leucopenia, VitaminB_{12}, Folic acid.*

Introduction

Cancer is a group of diseases characterized by uncontrolled growth and spread of abnormal cells. If the spread is not controlled, it can result in death [1]. Cancer is caused by both external and internal factors. The external factors are tobacco, infectious organisms, chemicals and radiation. The internal factors are inherited mutations, hormones immune conditions and mutations that occur from metabolism. These casual factors may act together or in sequence to initiate or promote the development of cancer [2]. Cancer is treated by surgery, radiation, chemotherapy, hormone therapy, biological therapy and targeted therapy [3]. The extravasation of chemotherapeutic drug and radiation can be serious adverse event that can damage internal tissues. After this treatment there may be a marked increase or decrease in leukocyte count. Leukocytes are produced from bone marrow and they are found throughout the body including blood and lymphatic system[4]. There are 5 different and diverse types of leukocytes [5]. They are: Neutrophils(60-70%) also called as polymorphonuclear cells and their main function is phagocytosis which results in digestion of bacterial organisms and debris. Lymphocytes (20-30%) measurement reflects a combination of the T and B cells. Their function is to combat acute viral infections and chronic bacterial infections. Monocytes (2-5%)also called as monos and play a vital role in phagocytosis of bacteria. Monocytes generally last longer in circulation than neutrophils.Eosinophils (2-3%) also called as eosand their main function is during allergic reactions and parasitic infections involved in inflammatory process and allergic reactions. Basophils (0-1%) also called as mast cells or basos act as an anticoagulant. These leukocytes continuously circulate throughout the body and their count increases in certain infections [6].The Infiltrating inflammatory cells have an important character in the rapidity and spread of tumors [7, 8]. With the help of specific chemokines actions when it’s released, the tumor microenvironment monitors the migration of the leukocyte and many important functions of these cells when they arrive at the tumor site. The autocrinesecretion of chemokines by the tumor cells brings in the action of inflammatory cells such as monocytes and neutrophils, where its survival rate increases with rapid proliferation and dissemination [8]. The inflammatory part of a developing tumor involves a variety in the leukocyte population such as the neutrophils, dendritic cells, macrophages, eosinophils, mast cells and lymphocytes, where all these cells has the potential in developing more number of different mediators. [9]. However, macrophages and lymphocytes are the most common cell types found infiltrated in the stroma and in neoplastic fluids [10, 11].Thechemokines such as MCP-1 attracts these leukocytes and they are regulated

during activation, the expression of normal T-cell occurs, and there is secretion (RANTES). The communication between the increased levels of MCP-1 and RANTES expression and the action of tumor-associated macrophages is increasingly reported in cases of breast cancer [12] and in cervical cancer [13]. Certain Clinical studies have studied the correlation relating the increased number of infiltrated macrophages and the poor prognosis rate for breast, prostate, ovarian, cervical, endometrial, esophageal and bladder cancers [14].The infiltrating inflammatory cells are capable of having pleiotropic functions: inhibition of tumor growth by non-specific cytotoxic mechanisms and initiation of cell lysis, or conversely promotion of tumor development by the release of inflammatory mediators [15].Pro-inflammatory cytokines promotes thedevelopment of migration, differentiation and activity of antigen-presenting cells and may favorably affect survival of cancer patients. Tumor-infiltrating leukocytes can produce vascular endothelial growth factor (VEGF), IL-8 and matrix metalloproteinases that mediate tumor invasion and angiogenesis [16].The prostaglandins and NO, produced by cyclooxy-genase-2 and inducible NO synthase, influences human tumor development [17]. NO is consistently evaluated at nanomolar concentrations in the microenvironment of the tumour and has been found to aid in tumor genesis [18]. The factors determining the outcome of these competing effects of the inflammatory response during tumor development are still undefined [15].The host response to malignant tumors includes not only the local changes in tumor microenvironment, but also involves the systemic effects. In terms of inflammatory response, neoplasia is a paradox. Tumors produce factors such as the chemokineswhich recruit leukocytes, but a deficient inflammatory response is seen at sites remote from the tumor [8, 19]. The Circulating chemokines factors have the capacity to desensitize leukocytes to migratory stimuli or, the tumor may produce anti-inflammatory mediators. Therefore, a systemic deficiency in inflammatory response could coexist with continued leukocyte recruitment to the tumor site [8].The most common systemic alterations assessed in patients with malignant solid tumors are leukocytosis and neutrophilia. These are the hematological conditions which is significantly correlated with advanced disease and, consequently, with poor prognosis [20]. Leukocytosis is defined as a condition often occurring in a clinical setup, usually caused by an elevation in the number of neutrophils, which represent 50 to 60% of total leukocytes. Etiologically, leukocytosis is a primary pathological condition affecting the white blood cells, but it frequently arises as a reaction to infection, chronic inflammation and cancer [20]. Neutrophilia is a condition

found to be an independent prognostic factor, associated with reduced survival in human metastatic melanoma, pancreatic carcinoma, and renal carcinoma [16, 21, 22]. A high pretreatment count of neutrophils in blood was confirmed as an independent prognostic factor for short overall survival in stage IV melanoma patients undergoing interleukin-2 immunotherapy. Furthermore,a high overall leukocyte count was a predictor of short overall survival. Since immunotherapy with cytokines induces adverse effects in almost every patient, it is important to avoid treating patients who are predicted not to benefit from the treatment [23].The correlation between the lymphocyte count and the clinical response to chemotherapy was assessed in lung, colorectal, breast and prostate cancer patients. Independent of tumor histotype and chemotherapeutic regimen, the average number of lymphocytes was significantly reduced in patients with progressive disease following chemotherapy. Conversely, lymphocytosis was observed in patients who achieved an objective tumor regression in response to chemotherapy, and lymphocyte count which at the end of treatment was significantly increased than values which was calculated before the beginning of treatment. A possible mechanism for this increase in lymphocyte count may be modulation of the cytokine network by chemotherapy, that corrects increased endogenous production of immunosuppressive cytokines [24]. In patients with locally advanced cervical carcinoma, univariate and multivariate analysis showed that a greater baseline lymphocyte count was the best predictor of a complete clinical response and progression-free survival after chemoradiation [25].

A study of patients with metastatic renal carcinoma during immunotherapy with interleukin-2 and interferon-alpha showed that changes from baseline in the total lymphocyte counts 4 weeks after treatment were significantly higher in the responding patients than in the non-responding patients, whereas no difference was observed in eosinophil counts [26]. An accumulation of immature or defective circulating leukocytes could facilitate a systemic immune dysfunction, while the presence of those cells at the tumor site could facilitate tumor growth. In several cancers breast, prostate and glioma; it was found that systemic distribution of immature dendritic cells was more evident in patients with advanced disease [27] . Dendritic cells are antigen presenting-cells that are potent initiators of a primary immune response. They originate from bone marrow progenitors, which circulate in peripheral blood and subsequently give rise to immature dendritic cells that reside in peripheral

tissues [31]. This study helps to identify the change in leukocyte count and also its morphological changes due to radiation.

Materials and Methods

Total leukocyte count and differential Leukocyte count can be done from same smear preparation. For about 15 post therapeutic cancer patients in Saveetha Dental College peripheral blood was drawn and smear was made on glass slide. The materials used for staining leukocytes are blood sample, glass slide, spirit, cotton, lancet, leishman stain, distilled water and stop watch. The count was done manually.For total count, the slide is focused under 45x and the number of leukocytes in 10 successive fields was noted. From this the total Leukocyte is counted by using the following formula:

$$\text{Total count} = \frac{\text{Total number of cells counted}}{10} \times 2000 \text{ cubic mm}$$

For differential count cedar wood oil is used, the slide is focused under 100x, the Leukocyte count is made to complete 100 boxes. This is repeated for all the patients and the count is determined.

Result

Staining was done on blood smears collected from the cancer patients depicted various changes in total and differential leukocyte count in post therapeutic cancer patients.

Table 1: Changes in TC & DC in peripheral blood of post therapeutic Cancer patients

S.No	Patient Name	Age/Sex	Type of Cancer	Total Leukocyte count	Differential count				
				(Cells/cmm)	N	L	E	M	B
1	Mohandas	36/Male	Oral Cancer	16800	76	21	2	1	-
2	Lakshmi	60/Female	Uterine Cancer	4600	50	24	19	6	1
3	Kolleshwaran	38/Male	Lung Cancer	9600	68	29	3	-	-
4	Gopal	47/Male	Neck Cancer	7600	75	21	3	-	1
5	Kalyani	45/Female	Intestine Cancer	8600	62	35	3	-	-
6	Kurian	80/Male	Oral Cancer	17200	65	32	3	-	-
7	Kanchana	38/Female	Stomach Cancer	7200	65	33	2	-	-
8	Murali	63/Male	Tongue Cancer	5400	56	38	4	-	2
9	Chiranjeevi	22/Male	Liver Cancer	9400	48	49	3	-	-
10	Ravi	38/Male	Stomach Cancer	8200	48	46	4	2	-
11	Krishnaveni	50/Female	Uterine Cancer	4500	53	43	3	1	-
12	Selvi	48/Female	Uterine Cancer	2800	64	28	7	-	1
13	Malliga	47/Female	Uterine Cancer	6000	64	33	2	-	1
14	ConskaleDiwakar	48/Female	Breast Cancer	6400	50	50	-	-	-
15	Anjali	42/Female	StomachCancer	7400	48	49	2	1	-

In the above table, N L E M B refers toN – Neutrophil L- lymphocyte E- Eosinophil

M-Monocyte B- Basophil

From the above table we can say that oral cancer patients sufferedleucocytosis and are said tohave normal differential count. Uterine cancer patients mostly have leucopenia and differential count was normal except one who had eosinophilia. Other cancer patients have a normal total leukocyte count. Stomach cancer, breast cancer and liver cancer patients suffer from lymphocytosis and neutropenia.

Discussion

Aquestion which arises in cancer biology is how tumor development leads to changes in the number of circulating leukocytes . A possible mechanism is the development of soluble factors such as the granulocyte and macrophage colony stimulating factor (GM-CSF) by tumor cells, which has the potential of mobilizing precursors in the bone marrow; or vascular endothelial growth factor (VEGF) and interleukin-6, both of which alter cell differentiation [28].White blood cell count has been suggested as an significant indicator in disease activity which is to be closely evaluated in patients with G-CSF-producing renal cell carcinoma. Pronounced neutrophilia is a manifestation of the strong host immune response elicited by photodynamic therapy of tumors. The cause of this neutrophilia was shown to be complement activation, which triggers the release of complement factors and at least a dozen secondary mediators including tumor necrosis factor, IL-1 , IL-6, IL-10, GCSF, prostaglandins and leukotrienes [29] The circulating neutrophils are consistently higher in mice deficient in the small GTPaseRac2 than in wild-type mice. The depletion of lymphocyte with consequent reduction of innate cellular immunity is a very severe clinical problem that can develop during cancer progression and cytoreductive therapies. Lymphopenia is a result of tumor-induced mechanisms involving the impairment of antigen presentation, activation of negative co-stimulators signals, and production of immunosuppressive factors, resulting in a marked reduction in T-helper lymphocytes [30,31] Along with this occurrence cancer cells may develop the expansion and recruitment of regulatory cell populations that plays a role in the immunosuppressive network; these include regulatory T cells (Tregs), myeloid suppressor cells and distinct subsets of immature regulatory dendritic cells. Development ofimmunosuppressive mediators such as IL-10, NO and transforming growth factor by tumor cells are responsible for evasion of immune surveillance; reduced production of these mediators restored a lymphoproliferative response [32]. The innate immunesystem triggers an anti-tumor response. The thymic pathway ismostly compromised in adults recoveringfrom

lymphopenia. Due to this , T cells depends upon peripheral expansion to restore cell numbers, through the stimulation of high cytokine levels [33].

The count done manually may vary from person toby person but gives an idea on the changes in count of post therapeutic cancer patients. The patients suffering from leukocytopenia, leukocytosis, neutrophilia, lymphocytosis, neutropenia and eosinophilia must be treated immediately as it may even result in death [34]. In all patients smear a characteristic features were seen, hypersegmentation and hypergranulation of neutrophil [35]. Hypersegmentation refers to neutrophils having more than 5 nuclei and hypergranulation refers to increased number of granules in the cytoplasm [36] This occurs due to deficiency of vitamin B12 or folic acid [37]. We all know that during surgery and radiation exposure vitamin B12 and folates are destroyed thus resulting in hypersegmentation and hypergranulation of neutrophils [38].

Conclusion

A pilot study has been made with 15 patients from Saveetha Dental College. All smears had hypersegmentation and hypergranulation of neutrophils clearly. This indicates that vitamin B12 and folic acid are very much necessary which has been depleted due to surgery and radiation. Many patient suffer from leukocytopenia, leukocytosis, neutrophilia, lymphocytosis, neutropenia and eosinophilia .There are many marked changes in total and differential leukocyte count of post therapeutic patients which has to be considered.

Abstract

Introduction: Human oral cavity in health is normally colonised by different microbiological flora predominantly with Candida.*Candida*is recognized as a normal commensal but can become a pathogen during favourableconditions such as immuno-compromised status like diabetes, ill filling dentures, nocturnal wear of the denture, age of the dentureand unhygienic maintenance of the dentures. Diabetics have an increased predisposition to the manifestation of candidiasis, which is associated with poor glycemic control and therapeutic dentures. Denture stomatitis is a common inflammatory reaction, multifactorial etiology, which is usually associated with Candida species, particularly Candida albicans, due to its high virulence, ability to adhere and form biofilms on oral cavity tissues and denture surfaces. Acrylic dentures which are usually ill fitting with suboptimal hygiene, act as reservoirs of infection.The aim of the study was to assess the prevalance of candidiasis among diabetic and nondiabetic denture wearers and the variety of candida species seen.

Materials and Method;A total of 30 individuals were enrolled in the study. Of the subjects, 15 were diabetic denture wearers and 15 were diabetic non-denture wearers. The salivary samples were collected in sterile containers and processed in Sabouraud dextrose agar (SDA) and incubated at 37 C for 48 hours.

Result: Out of the 30 subjects the prevalence of candida species was 86% in diabetic denture wearers and 46% in diabetic non-denture wearers.

Conclusion: The rate of candidal growth was higher in denture wearers with Diabetes when compared to non-diabetic denture wearers.

Keywords*: candida, denture wearers, diabetesmellitus,oppurtunistic, poor oral hygiene*

Introduction

In healthy individuals, oral cavity harbors many different spectra of micro-organisms. There are about 300-400 species of micro-organisms and 20 species of Candida in the oral cavity [1]. Most of the yeast infection in the oral cavity is caused by the genus Candida. Any changes in the oral cavity, such as tooth loss and denture wearing will cause changes in the oral micro flora [2]. *Candida* is recognized as a normal commensal of almost half of the population which does not cause any harmful effects [3,4]. But *Candida* can become a pathogen during unfavourable conditions and immuno-compromised status such as diabetes, trauma due to ill filling dentures, nocturnal wear and age of the denture, other systemic conditions andunhygienic maintenance of the dentures by the patient. These makethe oral cavity a suitable environment for Candida to turn pathogenic [5].*Candida* species also have the affinity to adhere to, and subsequently colonize, the denture acrylic resin material[6]. Oral Candidiasis is an opportunistic infection which causes pathological changes in the mucosal surface of the oral cavityThis is due to the prosthesis that acts as a focus and trauma caused by the denture facilitates the infection. Candidiasis may appear as various symptoms including pain, burning sensation, difficulty in swallowing, change of taste, but often they are asymptomatic [7,8].

Candida in the oral cavity may be present in two distinct forms,either as floating planktonic cells (blastopores, blastoconidia) and/or in an organized biofilm. Poor oral hygiene, practices such as failure to remove the denture whilst sleeping and poor denture cleansing allows the accumulation of biofilm [9], which is defined as structured microbial community that is attached to a surface, consisting of more than 10^{11} microorganisms per gram of dry weight and surrounded by a self-produced extracellular matrix. It has been recognized that unlike dental biofilm, the biofilm that forms on denture materials harbours a much larger population of yeasts [10]. Proliferation of bacteria and fungi can cause bad breath, acrylic resin pigmentation and staining, formation of

calculus deposits and the development of chronic atrophic candidiasis, also known as denture stomatitis. Candida albicans is able to utilize special mechanisms that allow it to be able to switch back and forth from one form to another (from budding yeast form to pseudohyphal, to hyphal forms) [11,12]. Morphologic transition from the yeast to hyphal state is one of the key factors in the pathogenic activity of Candida albicans.

Diabetes mellitus is a chronic metabolic disease, marked by high levels of blood glucose[13].Immunodeficiency and increased susceptibility to opportunistic infections are seen in diabetic patients. Diabetes have an increased predisposition to the manifestations of oral diseases like candidiasis, which is associated with poor glycemic control and therapeutic dentures[14]. This also contributes to xerostomia, which may be due to increased glucose levels in oral fluids or immune dysregulation[15].

Wearing complete denture is a risk factor, which can promote colonization of *Candida*, produce Candidal biofilm and result in oral candidiasis. About 50- 65 % of patient wearing dentures have been reported to have over growth of oral Candida, leading to Candida associated denture stomatitis (inflammation of the denture bearing site of the mucosa).Additionally, Candida has affinity for the acrylic surface of dentures and non- renewing surfaces such as teeth, dental fillings [16,17]. Surface characteristics of denture base acrylic resins, such as hydrophobicity, have generally been acknowledged to be one of the factors contributing to the adhesion, which is a crucial step in biofilm formation.

Wearing dentures is a contributingfactor which can affect the oral health and hygiene. This should be taken into consideration while making predictions and assessing oral health management. Association of denture and diabetes can increase the incidence of oral *Candida* disorders in diabetic patients.Candidiasis may appear asvarious symptoms including pain, burning sensation, difficulty in swallowing, change oftaste, but often they are asymptomatic[18].

Many studies have been done previously regarding prevalence of candidiasis among diabetic denture vs non-diabetic denture wearers but not much is known about the variety of species seen in them. The aim of the present study was to assess the prevalence of *Candida* and species diversity on the denture of diabetic and non-diabetic denture wearers.

A total of 30 subjects participated in the study. Fifteen subjects were denture wearers and fifteen subjects were non-denture wearers. All subjects were patients selected from the outpatient section of Saveetha Dental College and Hospital, Chennai. This study has been approved by the scientific review board of Saveetha dental college and hospitals. Patients included in the study were diabetic denture wearers. The controls included non-diabetic denture wearers. The subjects belonging to the age group between 40-80 years were included in this study.The exclusion criteria includes smokers, patient who are already treated or currently taking antibiotics, antifungal, steroids or immunosuppressive drugs in the past six months.

Patients were clearly explained about the purpose of the study, followed by a detailed information on demographics(name, age, sex),history of denture wearing, history of diabetes, type of diabetes, medications, duration, family history and history of other drugs was obtained using a questionnaire.

The diabetic status of the patients was determined by the history and the dentures worn included removable partial dentures and complete dentures. The salivary samples were collected in sterile containers. The samples were immediately transported to the Microbiology laboratory, Saveetha Dental College and inoculated in Sabouraud's dextrose agar (SDA) and incubated at 37 C for 48 hours for the recovery of *Candida* species.

Results

Out of the 30 subjects, the prevalence of *Candida* was 86% (n=13/15) in diabetic denture wearersand 46% (n=7/15) in non-diabetic denture wearers (Graph 1).

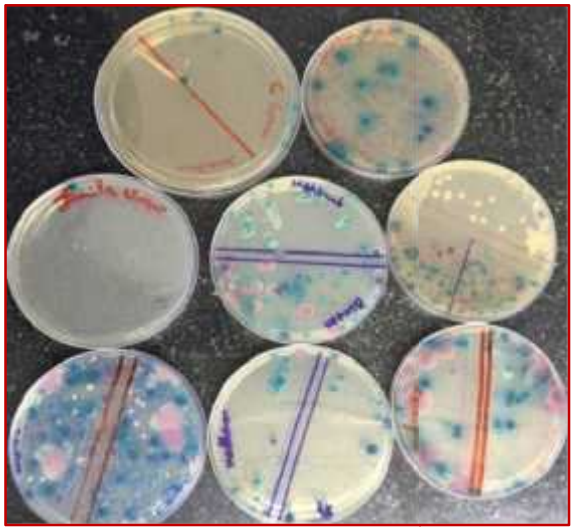

Figure 1: *Candida* colonization in diabetic denture wearers

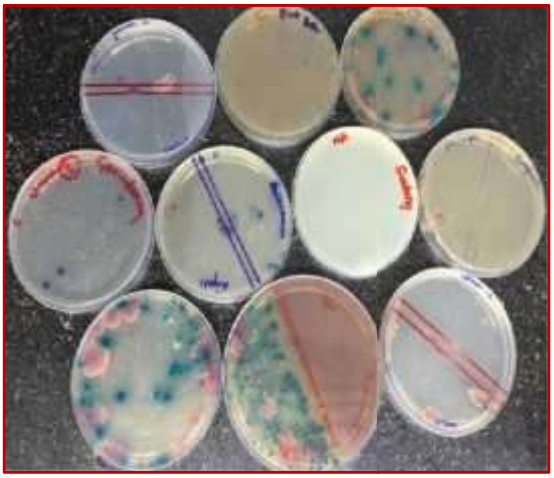

Figure 2: *Candida* colonization in non-diabetic denture wearers

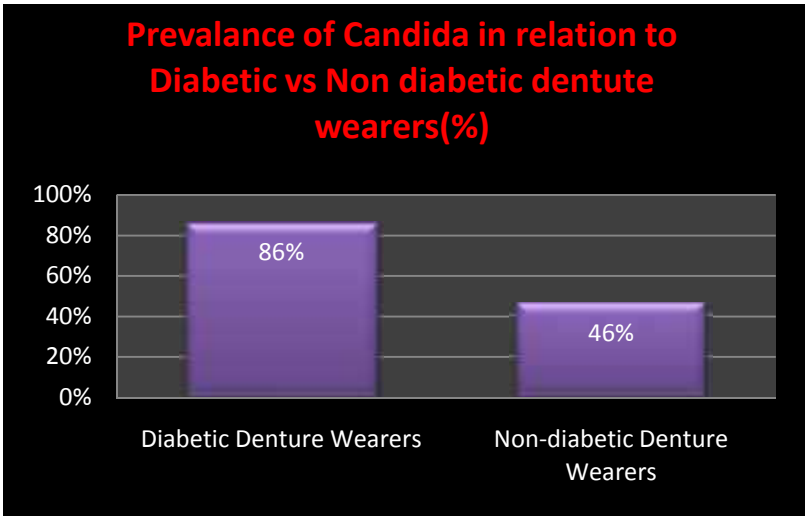
C. albicans was the most commonly isolated species in both groups followed by *C. tropicalis, C. kefyr, C. krusei,* and *C. parapsilosis.*



Graph 1: Prevalence of Candida(%) in relation to diabetic denture & non-diabetic denture wearers.

Discussion

The sole factor of this study was denture wearing increases the candidalcolonizationin the oral cavity and its growth rate was found higher in diabetic denture wearers whencompared to non-diabetic denture wearers due to their immuno-compromised status. The obtained results were similar to the studies reported by Mohammad HosseinLotfi-Kamran et al [19]and Divya Rani M et al. in 2014 [20].

Oral candidiasis, also known as oral thrush, is one of the most common oral mucosal infections. Symptoms of oral candidiasis include oral discomfort, pain, loss of taste, and aversion to food. *Candida albicans* carriage and a history of oral candidiasis are other significant risk factors for oral candidiasis[21]. The infection is caused by *Candida albicans*, a dimorphic fungal organism that typically is present in the oral cavity in a nonpathogenic state in about one- half of healthy individuals. Normally present as a yeast, the organism, under favorable conditions, can transform into a pathogenic hyphael form. Conditions that favor this transformation include broadspectrumantibiotic therapy, acidic saliva, dry mouth, tobacco, carbohydrate rich diets, patients receiving radiotherapy and chemotherapy, xerostomia, immune dysfunction, or the presence of removable prostheses.

Historically, the ancient Greek physician Hippocrate (460–370BC) described oral candidiasis as “disease of diseased” [22]. This infection was classified according to Newton in 1962, based exclusively on clinical criteria, into three clinical types: type I is characterized by localized simple inflammation or pin-point hyperaemia. Diffuse erythema and oedema of palatal mucosal areas covered by dentures are included in Type II which is the most common type.. Type III is described as granular surface or inflammatory papillary hyperplasia in central palate [23]. Classic study has shown that this oral inflammation may occur on the maxilla and mandible; however, it is more often associated with the maxilla, sometimes found under maxilla partial dentures, but only rarely beneath mandibular dentures [24].

Infection with *Candida Albicans*may present in any form [25,26].

Pseudomembranous candidiasis commonly known as ‘thrush’ presents as soft, multiple,raised white plaques of material resembling milk curds that can easily be wiped away. These plaques consist of tangled aggregates of hyphae.

Acute erythematous candidosis is a clinical form of Candida albicans characterized by localized erythema of the oral mucosa, with or without associated symptoms.

Hyperplastic candidiasis has also been named as candidalleukoplakia. It clinically appears as a well demarcated, slightly elevated, adherent white lesion of the oral mucosa ranging from small translucent lesions to large, dense opaque plaques, that cannot be wiped away by the clinician.
Angular cheilitis form presents as cracking, peeling, or ulceration involving the corners of the mouth. Patients with a reduced vertical dimension of occlusion, secondary to severe attrition or worn dentures, are particularly susceptible to the development of angular cheilitis. This is due to the increased folding of the soft tissue that is frequently seen at the corners of the mouth, creating a haven for the organism.
C. tropicalis is the most virulent of the non-Candida albicans Candida species. This may be due to its ability to adhere toepithelial cells in vitro and its ability to secrete moderate levels of proteinase [27].

*Candida parapsilosis*has become an emerging fungal pathogen.Individuals at the highest risk for severe infection include neonates and patients in intensive care units and patients with catheters or other implanted devices.*C. parapsilosis*has capacity to grow in total parenteral nutrition and to form biofilms. Factors involved in disease pathogenesis include the secretion of hydrolytic enzymes, adhesion to prosthetics, and biofilm formation[28].
Candida krusei,isatransient,infrequent isolate of minor clinical significance inhabiting the mucosal surfaces. Morerecently it has emerged as a notable pathogen with a spectrum of clinical manifestations suchasfungaemia, endophthalmitis, arthritis and endocarditis, most of which usually occurincompromised patient groups in a nosocomial setting [29].
Candida kefyr (formerly *Candida pseudotropicalis*) is a yeast with its teleomorph currently recognized as Kluyveromycesmarxianus [30].*Candidapseudotropicalis* is a species of fungus belonging to the genus *Candida* and order *Saccharomycetales*. Alongside other members of the genus, is, in due course, that causes candidiasis. It is also very infectious, particularly in immunodeficient individuals [31].

Oral thrush occurs when your immune system is weakened. Diabetes is an illness that affects the immune system and can contribute to oral thrush. Also in diabetes, saliva may contain enormous amounts of sugar, which encourages the growth of *Candida*.Higher incidence of candida infections affecting various tissues and organs is seen in diabetic people.. Excess sugars are an excellent source of fuel that can rapidly increase the growth of candida.Candidaspeciesplays a role in shaping of the intestinal flora, which has been found to regulate blood sugar levels through effects on organs such as the pancreas and liver.The ability of the body to eliminate candida depends upon the effectiveness of the white blood cells. High or low levels of sugar in the blood reduces the effectiveness of the white blood cells, allowing candida to progress the ongoing disturbances and imbalances.Most of these effects are in regard to Type II diabetes but candida has also shown to create autoimmune conditions like Type I diabetes.

Frequently, when the host defence system suffers because of any alterations, like immune deficiency, Candida albicans become virulent and generate candidiasis, that can be manifested through various clinical forms, involving one or more oral sites, up to affect the whole oral cavity and to disseminate into invasive forms [32]. Many studies have demonstrated that there is an increased oral colonisation of Candida albicans among the diabetic subjects [33], comparable studies by Manfredi et al. and Al-Karaawi et al. present contradictory findings with decreased rates of candidalpresence in diabetic subjects compared with healthy controls. The level of glycaemic control appears to be a more significant factor than the presence of the disease itself, because poor control can reduce salivary ow and pH, increase salivary glucose level. These factors facilitate oral candidal growth and colonization. The saliva of diabetics favors the growth of Candida albicansand it has been shown that there are more elevated counts of colonies of the yeast on the denture surfaces of diabetic in comparison with the nondiabetic subjects. Thus, diabetic patients are more likely to acquire oral candidal infections than non-diabetic patients [34].

Acrylic dentures act as a predisposing factor in the occurrence of oral candidal infection. The dentures can act as a reservoir of infection, because of the surface irregularities, micro porosities, improper fit and suboptimal hygiene[35]. Acrylic resins are pervious and exhibit more water sorption. This may help the candidial cells to adhere or to even penetrate the surface of acrylic

resin.Surface irregularities of acrylic resin acts as a factor in the entrapment of microorganisms.*Candida* species possess surface free energy closer to that of polymethyl methacrylate. This makes possible for the yeasts to nest and make difficult to eliminate bacteria by mechanical and chemical hygiene maneuver [36]. Denture age is shown to be an important factor as a result of poor fit, roughness, inadequate hygiene, and accumulation of plaque due to aging of denture. It was reported, that aging of the denture and release of residual monomer with time results in poorer fit which affects the contamination of the denture. Moreover, age of dentures was proportional to Candida colonization. 25% of the individuals using dentures for less than 1 year were diagnosed with denture stomatitis, whereas more than 84% of those using dentures for more than 5 years had the disease [37].

Unclean dentures are a chronic source of potentially harmful bacteria and fungi that may be associated with oral and systemic diseases. Good hygiene control of the oral cavity and the denture is important, because the porous material and surface biofilm formed can serve as a reservoir of fungal microorganisms and lead to relapse or reinfection [38]. Both the prosthesis that oral mucosa in contact with it must be involved in procedures for oral hygiene through brushing them after each meal with water or an effective, nonabrasive chemical agents.The most commonly used mechanical methods for cleaning of dentures are brushing with dentifrice or neutral soap and use of ultrasonic devices. The chemical methods involve denture immersion in chemical products, such as sodium perborate, sodium hypochlorite and chlorhexidinedigluconate [39]. The patients should be instructed to remove the denture during night and to immerse in a suitable antimicrobial cleansing agent.Instead of dry and water preservation, using cleaning tablets for acrylic dentures for overnight storage reduces denture biofilm and pathogenicity of the mass which will contribute to the overall hygiene [40]. Prior to reinsertion into the oral cavity, dentures should be thoroughlycleaned by soaking and brushingusing denture-cleansing solutions.

Conclusion

The present study concludes that*Candidal* infection is more common among denture wearers and it is strongly associated with diabetes mellitus. Hence controlling serum glucose level, drinking enough water in diabetic patients with xerostomia is essential to prevent candidiasis.

Abstract

Introduction:Tooth enamel is the most mineralized tissue of the human body. Teeth whitening is done by bleaching using in house preparations like Mcinnes solution or commercially available bleaching agents. This process could have deleterious effect on bond strength of orthodontic metal brackets when used in patient wearing fixedappliances.The objective of this research is to compare the effect of Mcinnes bleaching agent and commercially available bleaching agent on shear bond strength of orthodontic metal brackets.

Material and Methods: 15 human teeth bonded with orthodontic metal brackets were divided into three groups with 5 in each.Group 1: Teeth exposed to commercially available bleaching agent. Group 2: Teeth exposed to Mcinnes solution. Group 3: Control group without bleaching treatment is taken. Selected teeth were tested for shear bond strength using Instron universal testing machine. Data were statistically analyzed .

Result: We found that for enamel, the traditional approach of etching with a 35% phosphoric acid gel for 10 seconds and application of a primer led to accurate bonding of an orthodontic bracket.

Conclusion:The reason of the study is to determine whether bleaching can be done while patientis under orthodontic treatment .

***Key Words**: Orthodontic metal brackets,Mcinnes solution, Bleaching ,Shear bond strength.Enamel,Commercially available bleaching agent.*

Introduction

Bleaching of discoloured teeth may avoid invasive treatments such as prosthetic procedures that require the wear of a large quantity of dental tissue when they are performed.Sobleaching is considered a more conservative alternative,which significantly changes the appearance of the teeth and increases the patient's self esteem[1].Especially in patients who are undergoing orthodontic treatment,prosthetic procedures should be avoided or delayed until tooth movement has been performed[2]. Concentrated solutions of hydrogen peroxide are the most common agents used to bleach discoloured teeth.

The need for rebonding has resulted from the bond failure. One of the controversies that clinicians face with the bond failure is to decide if rebonding the same bracket would provide a sufficient bonding or a new bracket should be preferred. There are several commercial recycling methods available, but these are impractical to perform at the chairside. As a result, several in-office bracket recycling methods have been introduced. It has been found that the tensile bond strengths of the reused brackets were significantly lower than new brackets in vitro when a green stone was used to remove the surface layer of the residual resin on the bracket base.

Heating in flame was also found to decrease the bond strength dramatically.On the contrary, when sandblasting techniques were evaluated, it was found that sandblasting could increase the bond strength. Furthermore, articles tried to find a rapid office method of recycling brackets and found that sandblasting provided the simplest, most efficient way.

Nearly 30% of people benefit from orthodontic treatment, and the recent popularity of tooth whitening or bleaching also has a significant impact on the practice of dentistry and orthodontics. Although bleaching of vital teeth has been known since 1800's, the use of peroxide-based tooth whitening materials has increased recently. Some patients who are

interested in orthodontic treatment might have had their teeth bleached thus, it seems important to determine whether bleaching would significantly influence the bonding strength of orthodontic bracket adhesives to the enamel surface and how to reverse the effect in case it does.Previous studies have shown changes in the enamel structure and composition when exposed to 30.35% hydrogen peroxide for in-office vital bleaching. Some authors identified a substantial reduction in the bond strength. Acid etching of enamel is recommended with many dentinal bonding systems to improve the delivery of orthodontic treatment[3]. Claims of comparable bond strengths to enamel and dentin with conventional methods of bonding have meant that these adhesives are also suitable for orthodontic bonding .The development of an adhesive bond requires establishing intimate contact between the liquid adhesive and the solid adherent, minimizing the stress concentration at the interface and reducing the influence of environmental factors on the interface integrity .

The use of peroxide-based tooth-whitening materials haveincreased substantially in the past few years, despite many unanswered questionsabout their use.[4]The direct bonding of orthodontic brackets to the teeth is one of the most important advancements in modern dentistry. Three factors affecting the success of bonding are the tooth surface, the design of attachment base and the bonding material itself[5].The most common recommendation is to delay any bonding procedures after bleaching because the reduction of composite resin bond strength has shown to be transient.However, the recommended post-bleaching period for bonding procedures varies between 24 h and 4 weeksand hence it may be confusing for the clinician.[5,6]

Thus, this study was conducted to assess the changes in the shear bond strength (SBS) of metal brackets bonded with composite resins onto extracted teeth and exposed to bleaching solutions and also to compare the effect of Mcinnes bleaching agent and commercially available bleaching agent on shear bond strength of orthodontic metal brackets.

Several bonding protocols for effective bonding on enamel, composite, and ceramic surfaces have been introduced, but there is no agreement on the most effective procedure[6].Precoating of orthodontic brackets (with adhesive on the bracket mesh pad) was introduced to reduce the

number of operations needed for bonding as well as bonding time and bond failures (APC coated brackets, Unitek/3M, Monrovia, California, US). If precoated brackets are used, they should be stored in dark containers and the adhesive of these brackets should be cured using a dental light. Removal of adhesive flush around the bracket base is necessary for easier cleaning, and less white spot formation around the bracket base can be expected[7]. Prior studies reported conflicting results when using precoated brackets on different tooth surfaces. In this study, the accuracy of different procedures for bonding traditional metal brackets and precoated orthodontic brackets on different tooth surfaces was evaluated[8].

The cause of failures could be the alteration of enamel that follows previous bonding procedures. Bishara et al stated that the changes in bond strength after repeated bonding may be related to changes in the morphologic characteristics of the tooth surface caused by adhesive remnants[9].Various methods have been used to analyze tooth demineralization and remineralization when acidic bleaching is used, including techniques ranging from direct measures of mineral gain/ loss as in microradiography to indirect measures like iodide permeability and surface microhardness.

Material and Method

This study was done in the Department of Orthodontics and Dentofacial Orthopaedics,in Saveetha Dental College, Chennai .The bondstrengthanalysis was carried out at Central Institute of plastic engineering technology, Chennai. This study was carried out with an objective of assessing the effect of in-office hydrogen peroxide containing bleaching agent, and commercially available bleaching agent on shear bond strength of orthodontic metal brackets. Fifteen non-carious premolars extracted for orthodontic treatment were used for the study[10].Teeth with hypoplastic areas, cracks or gross irregularities of the enamel structures were excluded. No pretreatment with chemical agents such as alcohol, formalin or hydrogen peroxide or any other form of bleaching was allowed.The teeth were cleaned of blood and tissue debris and stored in normal saline after extraction. The saline was changed daily to avoid bacterialcontamination[11].

Teeth were divided into three experimental groups according to the bleaching agent used, and a control group, each containing 5 specimens.

-Group1 (n=5):deionised water(control).

-Group 2(n=5):Teeth bleached with mcinnes solution.

- Group 3 (n=5):Teeth bleached with commerciallyavailablebleaching agent.

Bonding Agent used:

Bonding agent used in the study was the Transbond XT (3M Unitek, Monrovia, USA) light cure orthodontic bonding system.

Bleaching Agentused :

A 35% hydrogen peroxide Pola office tooth whitening system (SDI Ltd., Victoria, Australia) was used to bleach the teeth .Each Group, the teeth were etched with 37% phosphoric acid gel for 30 seconds,then rinsed with water and dried till the enamel surface of the teeth showed frosty white appearance of etched enamel[12]

For those teeth that did not show white frosty appearance the above mentioned procedure was repeated. Then orthodontic metal brackets where bonded to tooth surface using light cure composite resin excess material was removed using a sharp probe and cured, using a light emitting diode (LED) light source and cured for 30 seconds. Group 2 was exposed to Mcinnes solution,Group3 was exposed to commercially available bleaching agent(Polo office bleaching agent).The teeth in all the groups were mounted individually on to a universal testing machine[13] for the debonding procedure.The data was statistically analysed.

Brackets:

One hundred stainless steel preadjusted edgewise upper bicuspid brackets (Ormco mini 2000 series, Ormco Corporation, Glendora, CA, USA) with 0.022 inch slot and micro etched base with a surface area of 9.63 mm2 were used for the study. The brackets were kept in the manufacturer's packaging until immediately prior to bonding and were handled at all times with bonding tweezers to avoid contamination[14].

The teeth used for the study were cleaned and then decontaminated with a 0.5% chlorine-T (Hi Media Laboratories, Mumbai) for 1 week at room temperature. The teeth were cleaned and stored in distilled water, which was changed twice weekly to prevent bacterial contamination. The root of each tooth was grooved in apical third with a diamond bur and then mounted in self-curing acrylic till cemento-enamel junction with long axis vertical[15]

Teeth were then divided into 5 groups randomly with 20 teeth in each group. The buccal surface of each tooth was polished with fluoride free pumice slurry, rinsed, and dried.

The buccal surface was then etched with 37% phosphoric acid for 30 s, rinsed for 15 s, dried, and checked for the frosted appearance[16].Transbond XT primer was applied to the enamel surface in a thin film with an applicator brush and light cured for 10 s. Transbond XT adhesive was applied to the bracket base and then, the bracket was positioned lightly on the buccal surface of the tooth. Excess adhesive was removed with an explorer and then, cured for 10 s on each side[17]

Group 2 (Bleached Group)

A 35% hydrogen peroxide bleaching agent was mixed and applied with a brush onto the tooth surface in a layer of approximately 1 mm in thickness, ensuring no enamel was visible. It was then exposed to the curing light twice for 10 s and the bleaching agent was kept in place for 16 min before washing away. Brackets were then immediately etched and bonded as in the control group.

Group :3

Teeth bleached with commercially available bleaching agent(Polo office bleaching kit)

Results

Table 1:Shear bond strength values of the different groups.

Group 1(Control group)	Group 2	Group 3
90.21	80.20	59.99
49.31	36.71	48.12
30.46	12.76	23.76

15.17	8.88	12.33
11.23	5.76	10.16

- Group 1(n=5):deionised water(Control)

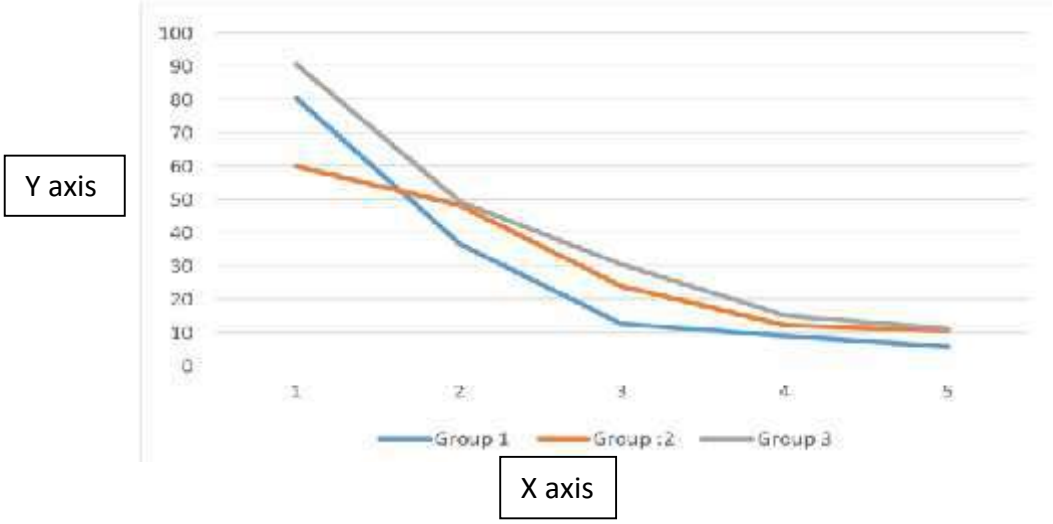
-Group 2(n=5):Teeth bleached with mcinnes solution.

-Group 3 (n=5):Teeth bleached with commercially available bleaching agent(Polo office)

Table 2 :- Statistically analysed values

Test groups	n	Mean	Sd	P value
Group 1	5	34.965	42.806	
Group 2	5	28.826	31.109	0.027
Group 3	5	30.872	22.185	

Graph shows that there is decrease in the shear bond strength of orthodontic metal brackets after treatment with Mcinnes solution and Commercially available bleaching agent(Polo office bleaching agent).



The value of the Walkthrough statistical test and the p = 0.027, indicates a statistically significant difference.

Discussion

Many patients are keeping their teeth for longer time but dislike the physiological darkening process that follows the laying down of secondary dentine. The use of chemical agents to remove certain intrinsic stains from the enamel or the dentin of vital teeth is not new. Hydrochloric acid and hydrogen peroxide have been used alone and in combination to remove stains associated with fluorosis, tetracycline and more recently trauma related injuries.The purpose of this in vitro study was to test an optimal protocol for bonding orthodontic brackets on various dental surfaces.

We found that for enamel, the traditional approach of etching with a 35% phosphoric acid gel for 10 seconds and application of a primer led to accurate bonding of an orthodontic bracket. For bonding orthodontic brackets onto composite surfaces, roughening of the surface with a drill and cleaning with water and air spray, followed by drying of the surface and application of a primer seems to be sufficient for effective bonding of brackets.[18] For bonding on ceramic surfaces, surface preparation using etching with hydrofluoric acid to roughen the ceramic surface for a mechanical retention followed by application of a thin layer of a silane-coupling agent (porcelain activator) was needed for a chemical bonding between the adhesive and the ceramic surface.[19]

It was expected that an increased roughness of the dental surface should increase the mechanical interlocking between the dental surface and the adhesive. In this study, we found an increase in surface roughness did not lead to an increase in bond strength. As permanent damage caused by the surface treatment required for bonding should be avoided, it can be concluded that roughening of the dental surface should and can be reduced without reduction of bonding efficiency. Studies evaluating differences in the efficiency of non-precoated and precoated brackets had different outcomes.

Theoretically, the placement of adhesive in the factory precoating should result in an effective connection between the bracket mesh and reduce bracket failures. In this study, no significant differences in bonding strength were found between these two groups, except when bonding brackets on a sandblasted composite surface. In general, the advantages of precoated brackets such as increased bonding efficiency, shorter bonding times, and less bond failures should be evaluated. The use of extracted premolars as tooth surfaces for bonding orthodontic brackets could have introduced some variables, such as the fluoride concentration in the enamel and the storage of the tooth after extraction at the start of the study. Finally, the results of this study are only applicable for the materials and methods used.

The use of chemical agents to remove certain intrinsic stains fromthe enamel or the dentin of vital teeth is not new.Hydrochloric acid and hydrogen peroxide have been used alone and in combination to remove stains associated with fluorosis, tetracycline and more recently trauma related injuries[20].

It was in the year 1966 that McInnes reported a technique that combined hydrochloric acid and hydrogen peroxide to remove fluorosis stains.He used a solution of five parts 30% hydrogen peroxide, five parts 36% hydrochloric acid and one part ethyl ether and applied the solution with a cotton wrapped toothpick to the areas of the teeth affected by the stain. After 10 to 15 minutes the teeth were washed with water and neutralized with a sodium bicarbonate paste.

In the present study McInnes bleaching agent and commercially available bleaching agent wasused.Articlehas reported that McInnes bleaching technique were specifically recommended for the treatment of teeth exhibiting endemic dental fluorosis because of its superficial nature, easy manipulation.All the samples used in the study were treated with Mcinnes bleaching agent and commercially available bleaching agent showed decreased value of Shear bond strength immediately after bleaching.

It is not uncommon for patient undergoing orthodontic treatment to develop stains on their teeth.The duration of Orthodontic treatment on an average is not less than 18 months.And it is not unfair from the patients point of view to desire a teeth whitening procedure such as bleaching.

There are number of studies regarding the interaction between the bleaching agents such as carbamide peroxide, hydrogen peroxide and bond strength of the composite resin to enamel.

The studies conducted by Adanir, etalin 2007 and Dishman in 1994 has found that there is reduced bond strength when the teeth is treated with the 35% hydrogen peroxide and immediately bonded with the light cure composite for bonding procedure[21]. Several authors have reported significant reduction in the bond strength of brackets bonded to enamel, immediately after bleaching.

One of the reasons suggested for the reduced bond strength is because of the release of free oxygen radical of the bleaching agents on the tooth surface[22].

The present study was conducted to find in-office bleaching agent on the bond strength of orthodontic bonding adhesive to enamel. In the present study, Group 3showed the least mean Shear bond strength among all the groups. Thus, the result of this study demonstrated that the reduction in Shear bond strength of composite resin to enamel treated with Mcinnes solution.

Conclusion

The present study shows that bleaching reduced the Shear bond strength significantly when compared to the control group.The Shear bond strength was drastically reduced when orthodontic metal brackets was exposed to commercially available bleaching agent compared to that of Mcinnes solution.

Abstract

Introduction: Milk is found to be one of the naturally available foods that have a beneficial role in oral and periodontal diseases. Milk and milk products are said to be rich in bioactive peptides and calcium which have important functions such as enamel-protection and anticaries effects.Milk product like cheese exhibit cariostatic effect. Casein, a phosphoprotein, is a major constituent of bovine milk .This phosphoprotein is actively involved with caries control. It was previous noted that increased consumption of casein rich food decreased the dental caries risk. This article is aimed to detect the co-relation between the intake of milk and milk products to the oral bacterial count.To determine the co-relation between consumption of milk and oral Streptococcus and Lactobacillus count.

Materials and Methods: To carry out this study, a screening questionnaire was prepared in order to separate the participants into 2 groups, one who consumed plain milk and the other group contained people who took milk with the addition of sugar. Following this screening, unstimulated saliva samples were collected from the participants half an hour after consumption of their respective variants of milk. After collection, these samples were transported to the laboratory. The samples were diluted in a dilution of 1 in 20 with saline after and they were cultured in mutants and lactobacillus agar respectively. They were kept overnight in an incubator which was maintained at 37 degree C. The bacterial colonies were counted in the next dawn.

Result : On comparing the bacterial count present on either side of the spectrum it was noted that the amount of Streptococcus in the test and control group was nearly equal , indicating that the sugar consumption does not instantaneously affect bacterial number. When the lactobacillus counts were scrutinized, difference that was sighted was noteworthy. Thereby the leading to conclusion that intake of sugar tends to alter the oral environment to a conducive state where the lactobacillus can actively thrive.

Conclusion: Diet has a local effect on oral health, primarily on the integrity of the teeth, pH, and composition of the saliva and plaque. Alterations in nutrient intake secondary to changes in diet intake, absorption, metabolism, or excretion can affect the integrity of the teeth, surrounding tissue and bone as well as the response to wound healing.

Key Words*: Milk, streptococcus, cariostatic, lactobacillus, sweeteners.*

Introduction

Milk is one of the naturally available sources of complete nutrition. With recent advancements in the field of food technology increasing importance is being received by products of less nutritive value. Flavouring agents which claim to submerse the undesirable taste of raw milk are being widely used in the past decades. Apart from all these addition to milk, the most important additive added are sweeteners be it sugar, honey, dates or artificial sweeteners. During the recent times many articles have claimed the cariostatic effect exhibited by milk and cheese. Various components of milk have been considered to be protective against dental caries. The elements like minerals, casein and other lipids present in milk exhibit a cariostatic action [1]. Articles have stated that long term consumption of non sweetened milk is linked with lower caries risk. Hence as a confirming study we desired to compare the immediate changes in the oral Streptococcusmutants and lactobacillus count in people who consume plain milk regularly and people who consume milk with the addition of sugar.

Materials and Methods

To carry out this study, a screening questionnaire was prepared in order to separate the participants into 2 groups, one who consumed plain milk and the other group contained people who took milk with the addition of sugar. Following this screening, unstimulated saliva samples were collected from the participants half an hour after consumption of their respective variants of milk. After collection, these samples were transported to the laboratory. The samples were diluted in a dilution of 1 in 20 with saline after and they were cultured in mutants and lactobacillus agar respectively. They were kept overnight in an incubator which was maintained at 37 degree C. The bacterial colonies were counted in the next dawn.

Results

The salivary samples collected from 15 individuals who consumed plain milk and 15 individuals who consumed milk with the addition of sugar which were cultured for S.mutants and lactobacillus were counted after overnight incubation[2]. On comparing the bacterial count present on either side of the spectrum it was noted that the amount of Streptococcusmutants in participants who had consumed plain milk and milk with the addition of sugar(half an hour before sample collection) that is the test and control group was nearly equal , indicating that the sugar consumption does not instantaneously affect bacterial number. When the lactobacillus counts were scrutinized, difference that was sighted was

noteworthy. Thereby the leading to conclusion that intake of sugar tends to alter the oral environment to a conducive state where the lactobacillus can actively thrive. The above mentioned information are presented in the form of a pie chart for quick cognition.

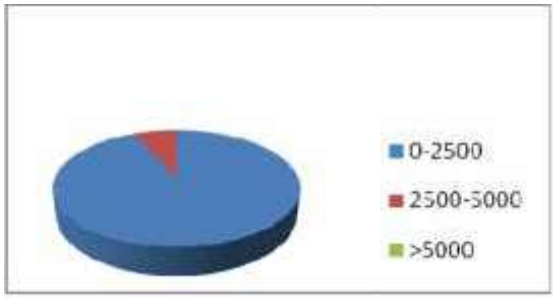

Figure 1: Shows the Lactobacillus count in subjects who consumed

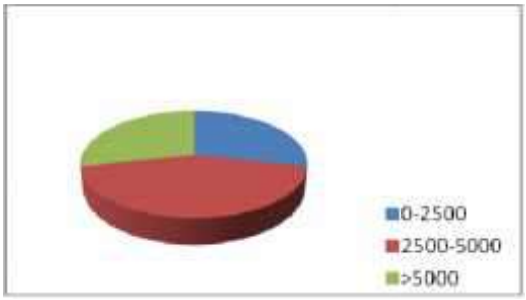

Figure 2: Shows the Lactobacillus count in subjects who consumed milk with the addition of sugar.

Discussion

Milk, one of the most commonly consumed foods, under certain circumstances exerts cariostatic effect. Bovine milk contains several proteases including plasmid, plasminogen, plasminogen activators, thrombin, cathepsin D, acid milk proteases, and aminopeptidase.

Milk and other dairy products not only have a low cariogenic potential but are also claimed to exhibit cariostatic potential. It has been culminated in many studies, involving in rats and *in situ*, that bovine milk and cheese safe guard against caries even under caries-susceptible conditions. The active constituents caseins and peptides, more precisely casein glycomacropeptide (CGMP) and casein phosphopeptide (CPP), is said to reduce the adhesion of cariogenic bacteria and reduce colonization [3]. CGMP binds to the tooth as micelle-like structures, which do not bind bacteria. CPP binds as minor complexes with calcium and phosphate, buffering calcium and phosphate when hydroxyapatite solubility increases by decreasing pH, and possibly explaining the acid-buffering effect from milk and cheese. Further proteose-peptones,provide protection against tooth tissue demineralization. In addition other milk peptides namely kappacin, lactoferrin, lactoperoxidase and lysozyme, possess innate immunity-like functions. Using milk components as a caries-prophylactic measure has not been studied in humans, but epidemiological studies confirm associations between milk and cheese intake and protection against caries [4] .

.

Milk contains 4–5% of the disaccharide lactose, which can be fermented by oral flora.

However, unless the bacteria are adapted to lactose, fermentation is signicantly less than from sucrose. Physiologically sucrose lowers pH of the oral cavity below 5.0, whereas lactose lowers pH to an approximate value of 6 . Inspite of variations among the homosapeins , it is a known fact that a pH lower than 5.5 is extremely injurious to the enamel of the tooth and lower than 6.2 to root tissues [5].Thus it is noteworthy that under normal circumstances the carbohydrate content of milk confers a low cariogenic potential to milk and dairy products but the act of drinking milk or chewing on cheese[6]. Removal of casein, fat or lactose from the milkdoes not modify the protective capacity on demineralization as the existence of free calcium and phosphate ions in the dairy products are have some favourable effect[7]. Apart from the above mentioned components milk still encompasses certain robust protective factors that are named as water-soluble proteose-peptones,amounting to 1 g l¼1 milk .However the action of milk is not exhibited in case of increase uptake of cariogenic diet in human beings. The cells of the oral epithelial and the secretory cells in the salivaryglands produce antibacterial peptides, commonly known as innate immunity peptides, that act immediately in the oral cavity upon the onset of an insult or challenge [8]. These peptides are formed as a result of proteolytic cleavage from larger precursor proteins, namely lactoferricin, which is both bacteriostatic and fungistatic. Recentlycaseino-macropeptide (CMP), a C-terminalfragment from bovine k-casein, has shown to inhibit the growth of *S. mutans* and *Porfyromonasgingivalis* ,responsible for caries production and periodontal diseases respectively. The other bioactive milk polypeptides, Lactoperoxidase andlysozyme, reduce the metabolism of *S.mutans*.

The beneficial activity of milk in the oral cavity is masked due to the addition of sugars and other types of artificial flavours and hence the caries activity is increased due to the creation of favourable environment. The oral flora plays a pivotal role in the initiation and propagation of dental caries[9].

Dental caries a disease of microbial origin which causes dissolution of the calcified part of the tooth structure is initiated by Streptococcus mutant's .Lactobacillus a causative organism for pit and fissure caries and smooth surface caries. The saliva present in the oral cavity acts as indictors for various disease conditions. The extensive presence of certain bacteria in saliva may act as markers for various pathological states

Many studies suggest that increase in Streptococcus and lactobacillus count is associated with increased caries risk and high DMFT and DMFS scores [10]. The immediate effect of sugar added milk in the oral cavity was to create a friendly environment for the lactobacillus to

survive thus confirming the risks associated with long term consumption .Apart from increased caries risk increase in lactobacillus count is found to be closely associated with conditions like nervous breakdown, hyposalivationetc . The cariogenic properties of bacteria is linked to sucrose metabolism are implicated in two pathogenic properties namely adherence and acid production.It has been shown that lactobacillus were able to adhere to various cell cultures and that the mechanisms of adhesion involved a certain level of specificity.

Lactobacilli cell surfaces have acrystalline protein layer which is responsible for the surface hydrophobicity[11]. The bacteria are able to adapt their surface hydrophobicity and to environmental changes like pH. The production of exopolysaccharides is a key factor in the adherence of dental biofilm.

The property of cariogenicity in latobacilli is due to their capacity to produce acids and their ability to grow and survive in acidic environment. These bacteria have a fermentative metabolism. Thus it results in an acidification of the environment, lowering the pH until values are less than 4.5. [12] the cariogenic properties of bacteria is linked to sucrose metabolism are implicated in two pathogenic properties namely adherence and acid production. It has been shown that lactobacillus were able to adhere to various cell cultures and that the mechanisms of adhesion involved a certain level of specificity.

The cariogenic properties of bacteria is linked to sucrose metabolism are implicated in two pathogenic properties namely adherence and acid production. It has been shown that lactobacillus were able to adhere to various cell cultures and that the mechanisms of adhesion involved a certain level of specificity.

Milk and dairy products are an inevitable, substantial part of the food consumed by Indians [13], though mean intake of dairy products is high , individual variations are ought to be taken into consideration in this diverse population. An array of studies have negatively correlated the development of dental caries and consumption of milk in children and adolescents. The strongest association was detected among children with high intake of any form of sucrose [14]. Further the development of root caries among gediatric people was halved on consumption of cheese and other probiotic products. Furthermore xerostomia , caused due to, head and neck irradiation, or primary and secondary Sjogren’s syndrome.

Overdose or adverse reaction of medication are often associated with either an experience of mild to severe discomfort in the oral cavity or rampant caries as a result of elevated numbers of mutans streptococci. Hyposalivation is also another concern which is repeatedly associated with issues during mastication, inadequate energy and nutrient intake With regards to lactobacillus, at present, there are no indications that the bacteria used in yoghurt and fermented products colonize the mouth[15]. Lactobacilli-containing products have reported to significantly decrease the number of mutans streptococci in saliva Thus a drink based on milk or milk components might can be used to serve both purposes. Milk and milk based drinks seem to possess a bunch of the biological and physical properties that are desired for a saliva substitute. Hence the need for frequent intake of liquid in order to lubricate and provide adequate moisture to the mouth is met, at the same time as providing caries protection to highly susceptible individuals [16].

Conclusion

The ultimate focus of the present study was to describe, seed in the minds of health care professionals, the potential anticariogenic properties of milk and cheese. This naturally available bioactive peptide which can be exploited in the field of dentistry due to its cariostatic properties is being pointed out as an important causative agent of caries due to the addition of certain products which may tend to alter its desirable property. The main focus is to notify the instantaneous effect of sugar on oral cavity when added along with a potential caries suppressing agent[17].The above mentioned effect of milk in the oral cavity provides nothing but a short term overview of the future benefit that can essentially be obtained by the consumption of non sweetened milk. Although forms of cariogenic, cariostatic, and anticariogenic food exists , the frequency of sugars consumption and other fermentable carbohydrates, retention time, nutrient composition, the potential of the food to stimulate saliva do exist as caries altering factors[18]. Caries risk which also depends on individual host factors like the presence of altered salivary pH, use of medications, incidence of systemic or local diseases that affect the immune system, andpersonal hygiene habit also play an essential role in the associated caries risk[19][20].

The cariogenic risk associated with individual foods is challenging to determine but regular consumption of plain milk can or may have innate potential to arrest the cavity or atleast inhibit the adsorption of sugar rich entities onto the tooth surface.[20]As mentioned various studies the remineralizing capacity of the tooth may also be exhibited. Thus it can be

concisely said that consuming plain milk on a regular basis without any addition can be beneficial. This beneficial activity of milk should not be ignored but should be exploited to the utmost level.

Abstract

Introduction: Diagnosis in dentistry is defined as the process by which the data collected from history taking, clinical examination, special tests and radiographic examination are combined to identify deviations from the normal status and render an appropriate treatment. Vitality testing and radiographic examination aids in an appropriate diagnosis of pulpal and periradicular diseases. The aim of the present study is to find out periapical radiographic changes involving vital teeth with acute pulpitis, chronic pulpitis and chronic hyperplastic pulpitis.

Materials and Methods: The present study was conducted in SaveethaDentalCollege, in the department of Oral Medicine and Radiology. Ethical committee clearance and the patient's consent were obtained.A clinical and radiographic examination was done on a total of 200 teeth diagnosed of pulpitis.Clinical diagnosis was made by correlating the history, heat test, cold test and electric pulp test. Radiographic diagnosis was made with an intraoralperiapical radiograph.The results obtained were subjected to descriptive statistical analysis.

Results: In a total of 200 teeth with pulpitis, 119 (59.5%) had chronic pulpitis, 58 (29%) had acute pulpitis and 23 (11.5%) had chronic hyperplastic pulpitis.

Conclusion: Thus to conclude, an acurate clinical diagnosis of pulp status and radiographic diagnosis of periapical changes of tooth with pulpitis is of paramount importance to render an appropriate treatment.

Key Words*: Periradicular changes, Pulpitis, Intraoral Periapical Radiograph, Heat test, Cold test*

Introduction

Dental caries is considered the chief cause of pulpal injury. The pulp reactions in deep carious lesions have been attributed to bacterial toxins, not to a direct result of bacterial invasion (1). Diagnosis in dentistry is defined as the process by which the data collected from history taking, clinical examination, special tests and radiographic examination are combined to identify deviations from the normal status and render an appropriate treatment. Vitality testing and radiographic examination aids in an appropriate diagnosis of pulpal and periradicular diseases (2). If a vital tooth with pulpitis is left untreated for a longer period, the infection may extend into periradicular tissues, such cases are referred to as pulpoperiapical periodontitis. The diseases of the pulp and periradicular tissues are progressive. The signs and symptoms vary depending on the stage of the disease. There are some limitations associated with pulp testing modalities and radiographic techniques when done individually (3). A complete interpretation of both pulpal and periradicular tissues must be done so as to provide an appropriate treatment. The aim of this study is to find out periapical radiographic changes in vital tooth with acute pulpitis, chronic pulpitis and chronic hyperplastic pulpitis.

Acute, Reversible Pulpitis: A mild to moderate inflammatory condition of the pulp caused by noxious stimuli, in which the pulp is capable of returning to the non-inflamed state following removal of the stimuli.

Chronic, Irreversible Pulpitis: A persistent inflammatory condition of the pulp, symptomatic or asymptomaticin nature with pulp becoming incapable of healing.

Chronic Hyperplastic Pulpitis: A productive pulpal inflammation due to an extensive various exposure of young pulp, characterised by the development of granulation tissue, covered at times with epithelium and resulting from long standing, low grade irritation.

Materials and Methods

The present study was conducted in Saveetha dental college from October 2016 to Decemberr 2016. Ethical committee clearance and patient’s consent was obtained. A clinical and radiographic examination was done on total of 200 teeth diagnosed with pulpitis. Vital tooth with acute pulpitis, chronic pulpitis and chronic hyperplastic pulpitiswas included and

tooth without opposing tooth, pathologically migrated tooth, mobile tooth, tooth with severe periodontitis, non vital tooth, tooth with periapical pathologies like abscess and cyst, maxillary molars and premolars was excluded. Clinical diagnosis was made by correlating the history, heat test, cold test and electric pulp test. Depending on history taking, clinical examination and pulp testing, clinical diagnosis of three types of pulpitis was made: Acute reversible pulpitis, Chronic irreversible pulpitis and Chronic hyperplastic pulpitis. Radiographic examination was done using intraoral periapical radiograph. Radiographic interpretation was done for the following findings: discontinuity in lamina dura (fig 1), thickening of lamina dura (fig 2), widening of periodontal ligament space (fig 3), periapical rarefying osteitis (fig 4), periapical condensing osteitis (fig 5), periapical condensing and rarefying osteitis (fig 6). The results obtained were subjected to statistical analysis.

Results

In a total of 200 teeth with pulpitis (table 1), 119 (59.5%) had chronic pulpitis, 58 (29%) had acute pulpitis and 23 (11.5%) had chronic hyperplastic pulpitis.

In 23 teeth with chronic hyperplastic pulpitis (table 2), 5 (21.7%) had widening of periodontal ligament space, 2 (8.7%) had discontinuity in lamina dura, 4 (7.3%) had thickening of lamina dura, 3 (13.1%) had periapical rarefying osteitis, 6 (26.1%) had periapical condensing osteitis and 3 (13.1%) had periapical condensing and rarefying osteitis.

In 119 teeth with chronic pulpitis (table 3), 27 (22.6%) had widening of periodontal ligament space, 16 (13.4%) had discontinuity in lamina dura, 21(17.4%) had thickening of lamina dura, 15 (12.5%) had periapical rarefying osteitis, 19 (16%) had periapical condensing osteitis and 11 (9.1%) had periapical condensing and rarefying osteitis.

In 58 teeth with acute pulpitis, 17 (29.3%) had widening of periodontal ligament space, 14 (24.1%) had discontinuity in lamina dura, 3 (5.2%) had thickening of lamina dura and 24 (41.4%) had no periapical changes.

Table 1: Types of Pulpitis

	N=200	**Percentage(%)**
Chronic hyperplastic pulpitis	23	11.5
Chronic pulpitis	119	59.5
Acute pulpitis	58	29

Discussion

It is significant to understand pulpal innervation characteristics in order to appreciate the mechanisms involved in the tests of pulpal vitality. Within the coronal pulp, nerve bundles diverge and branch out towards the pulpo dentin border, and emerge from their myelin sheaths (4),(5). Nerve divergence continues until each bundle looses its integrity and smaller fibre groups travel towards the dentine. This course is relatively straight until the nerve fibres form a loop and a resultant mesh termed the nerve plexus of Rashkow. Terminal axons exit from the Schwann cell investiture and pass between the odontoblasts as free nerve endings (6). This nerve plexus is well developed in the peripheral pulp along the lateral wall of coronal and cervical dentin, and along the occlusal aspect of the pulp chamber. Two types of sensory fibres are present in the pulp: the myelinated A fibres and unmyelinated C fibres. The A fibres predominantly innervate the dentine and are subgrouped according to their diameter and conduction velocities into Aβ and Aδfibres. The Aβ fibres may be more sensitive to stimulation than the Aδfibres, but functionally these fibres are grouped together. Approximately 90% of A fibres are Aδfibres. The C fibres innervate the body of the pulp. The Aδfibres have lower electrical thresholds than the C fibres, and respond to a number of stimuli which do not activate C fibres (7). Aδfibres mediate acute, sharp pain and are excited by hydromechanical events in dentinal tubules such as drilling or air-drying (8). The C fibres mediate a dull, burning, and poorly located pain, and are activated only by stimuli reaching the pulp proper (9),(10). C fibres have a high threshold and can be activated by intense heating or cooling of the tooth crown. Once activated, the pain initiated by C fibres can radiate throughout the face and jaws. C fibre pain is associated with tissue injury and is modulated by inflammatory mediators, vascular changes in blood volume and flow, and increases in pressure (11). As the intensity of the stimulus increases, more sensory nerves are activated which results in a progressive increase in the sensory response. The response to a given stimulus will be to the maximum where neural density is the highest. Important factors known to affect the response to pulp testing are the thickness of the enamel and dentin, and the number of nerve fibres in the underlying pulp.

Thermal tests include the application of cold and heat stimuli by various methods to the affected tooth, to determine sensitivity to thermal changes. Although cold and heat tests are based on sensitivity, they are actually conducted for different diagnostic purposes. A response

to cold stimuli usually indicates a vital pulp, regardless of whether that pulp is normal or affected.Contrasty, an increased response to heat stimuli is suggestive of pulpal or periapical pathology that may require endodontic intervention.

Cold Test

This test causes contraction of thedentinal fluid present within the dentinal tubules,resulting in a rapid outward flow of dentinal fluidwithin the patent dentinal tubules (12). This rapid movementof dentinal fluid results in 'hydrodynamicforces' acting on the Aδnerve fibres within thepulp–dentine complex, leading to a sharp pain, lastingduring the thermaltest (13). A large number of cold tests areemployed, the major difference between them is the degreeof cold that is applied to the affected tooth.Ideally, cold testsshould be done in conjunction with an electric pulp tester so that the results from one test will verify the findings of the other test. If a non-traumatized tooth does not respond either to electric pulp test or cold test, then the tooth is considered non-vital (14). The cold test is used to differentiatebetween reversible and irreversible pulpitis. Itshould be noted, whether stimulusapplication produces a lingering effect or if thepain subsides immediately on removal of the coldstimulus from the tooth. If the patient feels alingering pain, even after the cold stimulusis removed, a diagnosis of irreversible pulpitis given. Contrastly, if the pain subsidesimmediately after cold stimulus removal, adiagnosis of reversible pulpitis is given. The clinician should also take into considerationof other factors, such as a history of pain onlying down and the duration of pain. The diagnosisof reversible or irreversible pulpitis is onlya clinical diagnosis and may not correlate witha histological diagnosis.A simple method of applying a cold stimulusto a tooth is to wrap a sliver of ice in wetgauze and place it against the buccal surface,comparing the reaction between the test toothand a control tooth. Pencils of ice can be madeby filling a plastic straw or disposable syringe with water and freezing it in an upright position in a refrigerator.Ethyl chloride (boiling point – 41°C) may besprayed onto a cotton pellet, resulting in theformation of ice crystals, prior to applicationto the tooth. Dichlorodifluoromethane (DDM) (boiling point – 0°C) is a compressed refrigerantspray, which can similarly be sprayedonto a cotton pellet for cold testing (15). Another effective cold stimulus is frozen carbon dioxide (CO_2), also known as 'dry ice' or 'carbon dioxide snow' (boiling point – 72°C). This investigation is particularly effective when trying to assess teeth that have been restored with full-coverage metal restorations (16). When a cold test is

being done, one must begin with the most posterior tooth and advance towards the anterior teeth. This sequence will prevent any melted ice water dripping in a backward direction which may cause stimulation ofother posterior teeth, hence giving a false response.

Heat Test

This test can be undertaken using a heated gutta-percha stick or hot water. A guttaperchastick is heated with a flame or an electric heater until it becomes soft and glistens. It is then applied to the vaseline coated, buccal surface of the affected or test tooth. This test is difficult to use on posterior teeth because of limited access and a further disadvantage is that excessive heating may result in pulpal damage. Prolonged heat application will result in stimulation of Aδfibres initially, followed by the C fibres. Activation of C fibres may result in a lingering pain, therefore heat tests should not be applied for more than 5 seconds. However, inadequate heating of the guttapercha stick could result in the stimulus being too weak to elicit a pulpal response. The hot water can be administered through an irrigating syringe under rubber dam isolation, is also described as a means of heat testing (17). Frictional heat may be generated by using a rubber cup used for oral prophylaxis, without paste, against the buccal surface of a tooth (18).

Electric Pulp Test (EPT)

The objective of electric pulp test is to stimulate the intact Aδnerves in the pulpal dentin complex by applyingan electric current on the affected tooth surface. Apositive result is due to an ionic shift in thedentinal fluid within the dentinal tubules causing localdepolarization and subsequent generation ofan action potential from intact Aδ nerves. The electric pulp tester is a battery operatedinstrument, which is connected to a probe. Itfunctions by producing a pulsating electricalstimulus. The initial electric stimulus shouldbe at a very low value to prevent excessivestimulation and discomfort. The intensity ofthe electric stimulus is then increased steadily, and a note is made of the read-out on the digital display when thepatient acknowledges a sharp, tinglingsensation. The read out is not a quantitativemeasurement of pulpal health, but simplyimplies that the Aδfibres are sufficientlyhealthy to function of the pulp(19**)**.The electric pulp testis technique sensitiveand has a number of limitations. The requirementsof an electric pulp test are an adequate stimulus, an appropriate application method, and carefulinterpretation of results. Tooth isolation duringelectric pulp

testissignificant. Adequate drying of the enamel, placementof an interproximal plastic strip, and use ofrubber dam can prevent the spread of electricalimpulses to adjacent teeth or gingival tissue(20).Electric current can also be transferred toadjacent teeth through contacting metallic restorations (21). A conducting medium should also beused to ensure that maximum current passesfrom the electrode to the tooth surface (22).

The majority of radiographic periapical changes were seen in chronic pulpitis and chronic hyperplastic pulpitis. This might be due to the long standing inflammatory response, which has reached the periapical region through apical foramen of the infected tooth (23).Depending on the duration of infection, virulence of the microbes involved and the bacterial activity, the radiographic changes seen in periapical region can be widening of periodontal ligament, discontinuity in lamina dura, thickening of lamina dura, periapical rarefying osteitis, periapical condensing osteitis or periapical condensing and rarefying osteitis.

Similarly, Marmary et al (24), suggested a possible relationship between pulpitis and periapical changes. Olsson et al (25) and Sagne et al (26), also mentioned that the periapical changes may be due to the infection from the root canal of the infected tooth. In chronic, irreversible pulpitis, the partially necrosed pulp has functional sensory response and responds to vitality testing, but the radiographic picture may vary. In the present study, chronic pulpitis and chronic hyperplastic pulpits showed a predominance of widening of periodontal ligament space (22.6%) and periapical condensing osteitis (26.1%), respectively. In acute pulpitis, 58.6% cases showed periapical changes, in which, a predominance of widening of periodontal ligament space (29.3%) and remaining 41.4% cases showed no periapical changes. Dayal PK et al (27) has also shown similar results in his study with predominance of periodontal ligament space widening in chronic pulpitis and periapical condensing osteitis in chronic hyperplasticpulpitis.

Conclusion

Periapical changes are most commonly seen in chronic pulpitis and chronic hyperplastic pulpitis with predominance of periodontal ligament space widening and periapical condensing osteitis, respectively. Rapid advances in knowledge and advanced diagnostic aids in pulpal assessment should be used for more objective, accurate and proper diagnosis.

Abstract

Introduction: Salivary diagnosis is increasingly becoming an important field in dentistry. Saliva is adapted to protect the tooth against dental caries and it has an immense ability to wash the tooth surfaces, it alsocontrolsmineralization and demineralization. Saliva is the principal defensive factor in the mouth, and a reduction in its flow rate affects orodental health. A decreased salivary flow rate may cause a variety of unspecific symptoms and so establishment of patients saliva flow is of primary importance in oral pathology and dentistry. The purpose of undertaking this study is to assess the salivary flow rate in the study groups and correlate with the observed oral manifestation so as to explore the treatment modality of improving the saliva flow and there by oral health.

Materials and Methods: In this study about 30 individuals were taken of which 15 are diabetic and 15 are non-diabetic. The age group of the sample population varied between 30 to 83 years. Saliva collection from the patient was done after the breakfast. Unstimulated saliva was collected using draining method. Saliva was collected for a period of five minutes measured individually for each minute.The study was conducted in city medical college, Chennai, Tamil Nadu.

Results: This study showed significant variation in salivary flow rates between diabetes and health emphasizing that most of the oral conditions are closely correlated to salivary secretion of

the individual. Of the oral manifestations screened, we found 100% positivity for dental caries followed by periodontitis.

Conclusion: This research was undertaken to increase the awareness of oral complications among diabetes and health.

Key Words: *Diabetes mellitus, Saliva, Periodontal diseases. Dental caries, Hyposalivation.*

Introduction

Diabetes mellitus is a metabolic diseasewhich is caused by the total or partial absence of insulin secretion.as group of metabolic diseases which is characterized by increased glucose levels due to problem of secretion of insulin, by insulin action, or both. The other name of diabetes mellitus is iceberg disease[1]. Diabetes mellitus has affected about 285 million people of world population; in 2014 it has reached 387 patients whichis 8.7%.

Diabetes has become universally experienced growing public health concern and common chronic metabolic disease [2-5]. Diabetes mellitus stands as sixth leading disorder that leads to death. The factors that are responsible of inducing salivary disorders in diabetic patients is ageing, head and neck radiotherapy, systemic disorders, and several drugs.It is associated with many oral complications like periodontitis, dental caries, halitosis, mucosal ulcers and certain fungal infections. Saliva plays an important role in controlling the above mentioned complications. Salivary secretions are important for maintaining oral health, assisting in the mechanical cleaning and also serving protective functions through the physiological and biochemical mechanisms. Hypo salivation contributes to the development of many health problems that can have serious negative effects on the quality life of the patient, affecting their eating habits, nutritional state, palate, speech, and tolerance of dental prostheses. These effects may increase the risk of oral infection, including candidiasis, and the patient's susceptibility towards dental caries, periodontal disease, and tooth loss.Italso acts as a defensive mechanism for orodental problems which requires early diagnosis and intervenation.Measurement of

salivary flow rate is an invaluable diagnostic tool in determining the prognosis of alternative treatment plan (Stahl et al., 1990)[6].

Materials and Methods

The participants in this study were 30 individuals of which 15 are diabetic and 15 are non-diabetic. The age group of the sample population varied between 30 to 83 years. The study was conducted in private medical college, Thandalam, Chennail, Tamilnadu.

Collection of Saliva

Saliva collection from the patient was collected between 9 a.m to 12 p.m after the breakfast.The patient was asked to rinse his or her mouth with mouthwash prior to collection of saliva Unstimulated saliva was collected using draining method by asking the patient to sit quietlywith head bent down and mouth open to allow the saliva to drip from lower lip in sampling tube.saliva was collected for a period of five minutes;measured individually for each minute.

The Normality tests Kolmogorov-Smirnov and Shapiro-Wilks tests results reveal that the variables except age do not follow Normal distribution. Therefore to analyse the data Parametric & Non-Parametric methods are applied. To compare mean age between groups independent samples t-test is used. To compare the salivary flow rate between groups Mann Whitney test is applied. To compare proportions between groups Chi-Square test is applied, if any expected cell frequency is less than five then Fisher's Exact test is applied. SPSS version 22.0 is used to analyse the data. Significance level is fixed as 5% ($\alpha = 0.05$).

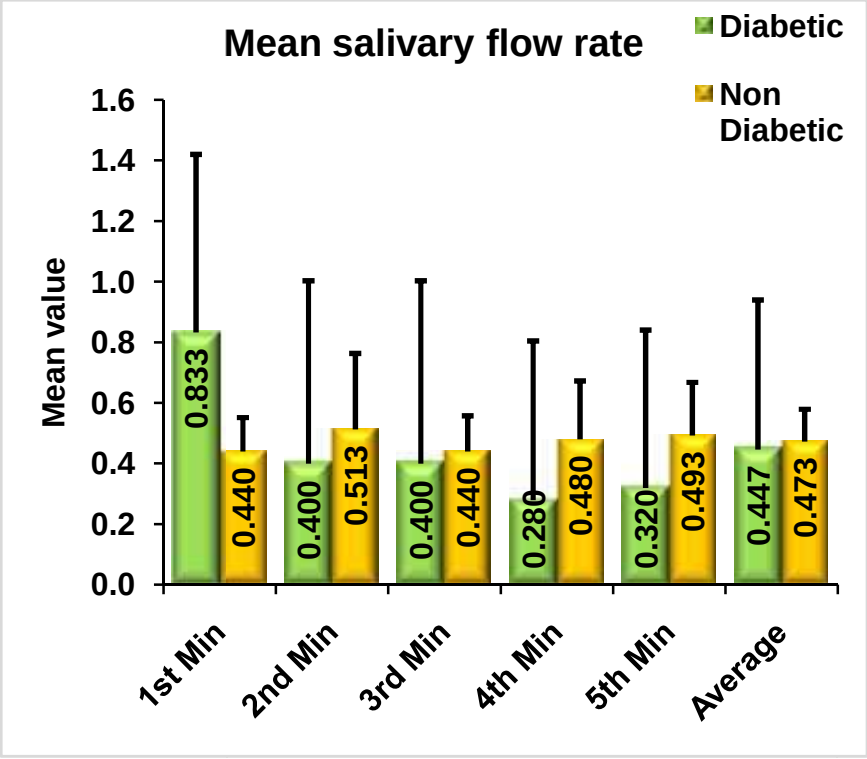

Figure 2: Salivary flow rate of first, second, third, forth. Fifth and the average

In this study the saliva is collected for 5 minutes, at each 1 minute the amount of saliva should be measured.In the 1st minute the mean salivary flow rate is significantly higher in diabetic than non diabetic subjects i.e. 18.43 on diabetic and 12.57 in non diabetic. Where as in second, third, fourth and fifth minute the mean flow rates has completely decreased compared to that of the non diabetic patients showing hyposalivation (Table 2-7), (Figure 2).

Table 8: Chi-Square test to compare gender proportions between groups

Gender	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	0.121
Male	12	80.0	8	53.3	20	66.7	
Female	3	20.0	7	46.7	10	33.3	

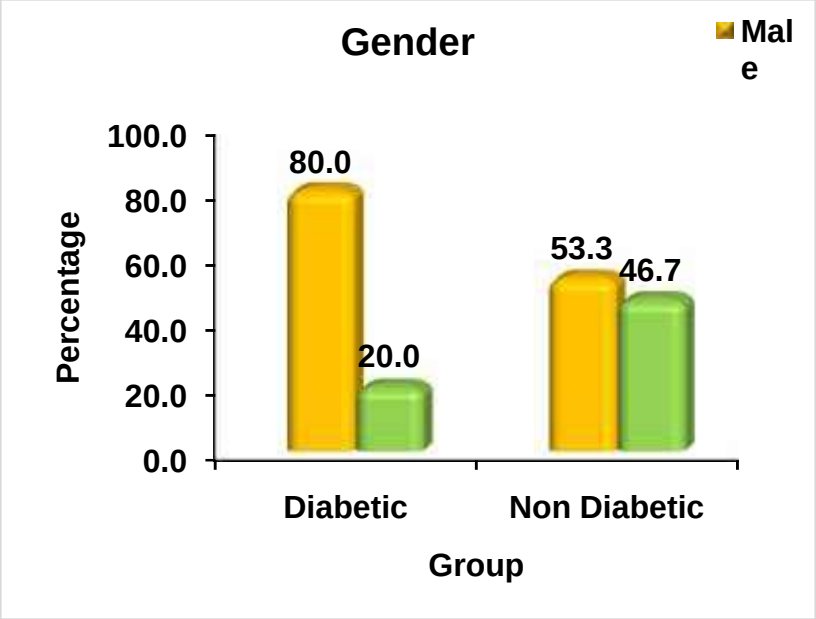

Figure 3: Comparison of gender proportions between groups

Among the diabetics there were 12 male and 3 female with mean age of 57 years. Among non diabetic patients there were 8 males and 7 females with mean age of 40 years with statistical significance of 0.121(table 8, Figure 3)

Table 9: Periodontitis in diabetic and non-diabetic

Periodontitis	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	11	73.3	3	20.0	14	46.7	0.003
No	4	26.7	12	80.0	16	53.3	
Total	15	100.0	15	100.0	30	100.0	

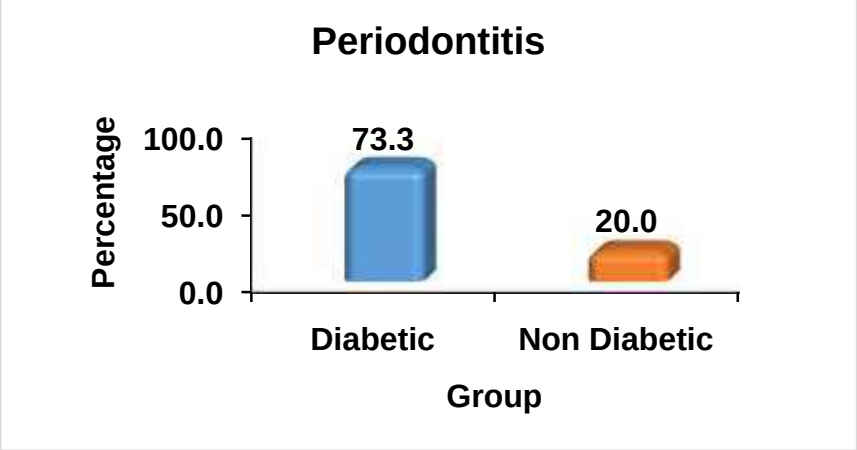

Figure 4: Periodontitis in diabetic and non-diabetic

According to the examination done on the patients regarding oral manifestation, about 73.3% of diabetic subjects have periodontitis where as only 20% periodontal problem seen in non diabetic with statistical significance (p=0.003)(Table 9, Figure 4)

Table 10: Oral candidiasis in diabetic and non-diabetic

Oral Candidiasis	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	2	13.3	0	.0	2	6.7	0.483
No	13	86.7	15	100.0	28	93.3	
Total	15	100.0	15	100.0	30	100.0	

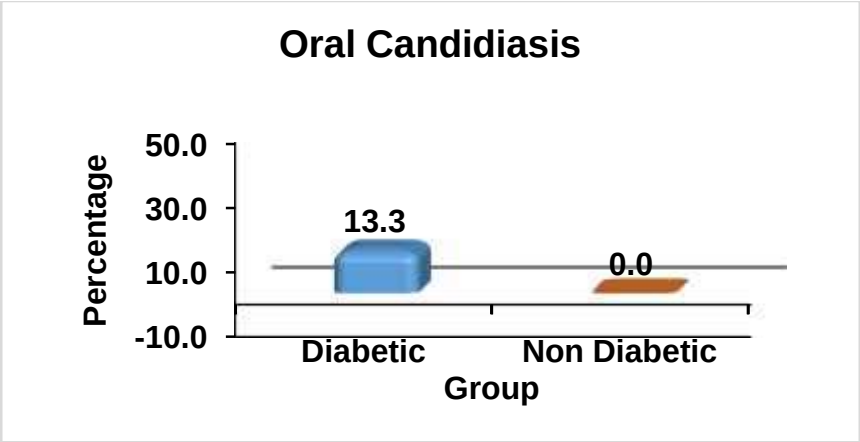

Figure 5: Oral candidiasis in diabetic and non-diabetic

13.3% of diabetic patients and 0% non diabetic subjects seems to have oral candidiasis with a statistical significance (p=0.483) (Table 10, Figure 5).

Table 11: Tooth loss in diabetic and non-diabetic

Tooth Loss	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	8	53.3	5	33.3	13	43.3	0.269
No	7	46.7	10	66.7	17	56.7	
Total	15	100.0	15	100.0	30	100.0	

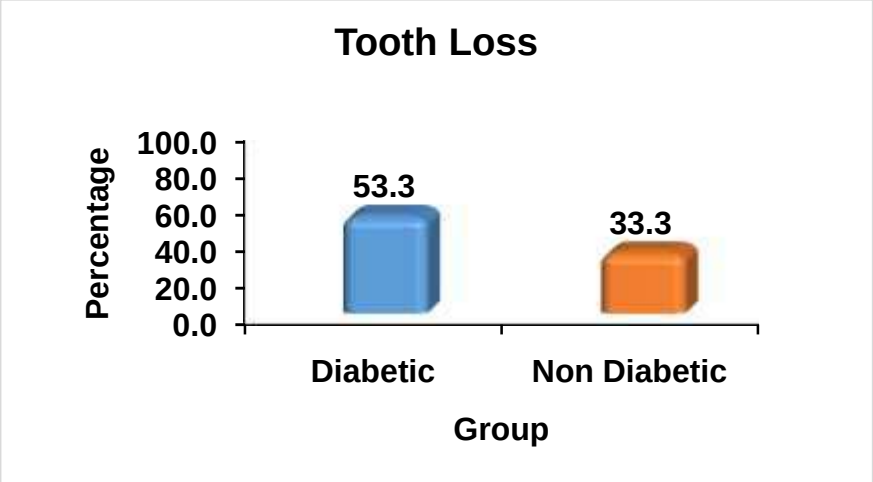

Figure 6: Tooth loss in diabetic and non-diabetic

53.3% of diabetic experienced tooth loss and 33.3% of healthy subjects shows tooth loss.(Table 11, Figure 6)

Table 12: Halitosis in diabetic and non-diabetic

Halitosis	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	7	46.7	2	13.3	9	30.0	0.109
No	8	53.3	13	86.7	21	70.0	
Total	15	100.0	15	100.0	30	100.0	

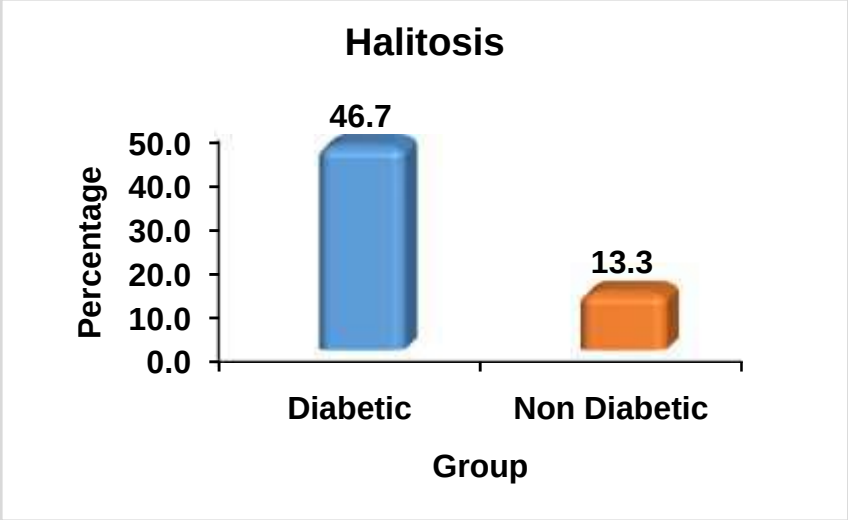

Figure 7: Halitosis in diabetic and non-diabetic

46.7% and 33.3% with statistical significance (p=0.269). halitosis is present highly in diabetic than healthy (Table 12, Figure 7)

Table 13: Dental caries in diabetic and non-diabetic

Dental Caries	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	15	100.0	8	53.3	23	76.7	0.006
No	0	0.0	7	46.7	7	23.3	
Total	15	100.0	15	100.0	30	100.0	

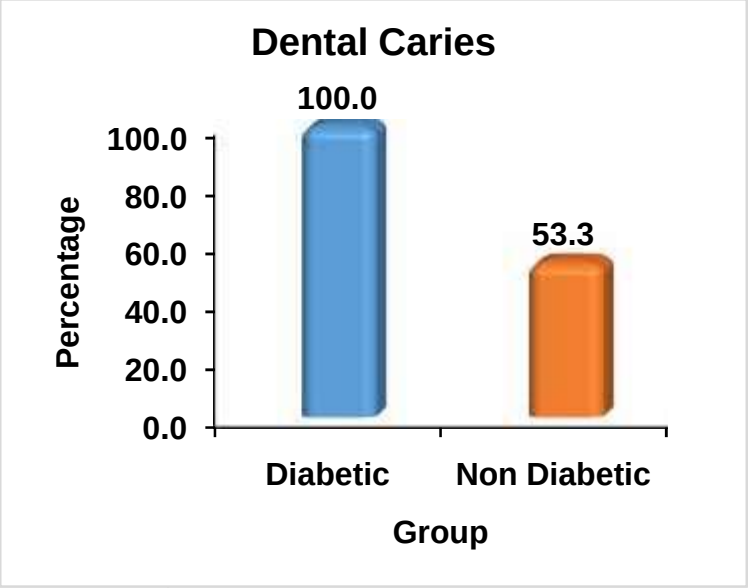

Figure 8: Dental caries in diabetic and non-diabetic

It is reported that all the diabetic subjects are subjected to dental caries where as in healthy the percentage came to half that is 53.3% (Table 13, Figure 8)

Table 14: Glossitis in diabetic and non diabetic

Glossitis	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	5	33.3	0	0	5	16.7	0.042
No	10	66.7	15	100.0	25	83.3	
Total	15	100.0	15	100.0	30	100.0	

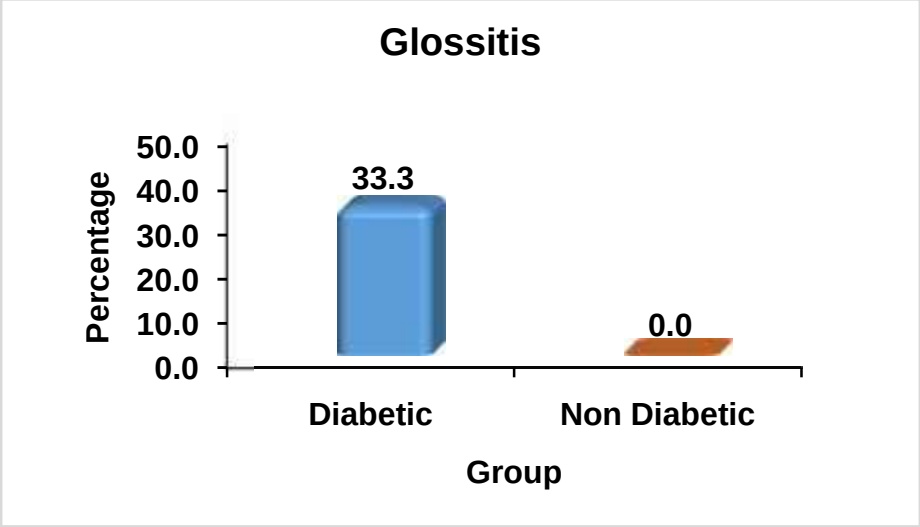

Figure 9: Glossitis in diabetic and non diabetic

33.3% of diabetic population reported to have glossitis (Table 14, Figure 9).

Table 15: Taste impairment in diabetic and non diabetic

Taste Impairment	Group						P value
	Diabetic		Non Diabetic		Total		
	N	%	N	%	N	%	
Yes	1	6.7	0	0	1	3.3	0.999
No	14	93.3	15	100.0	29	96.7	
Total	15	100.0	15	100.0	30	100.0	

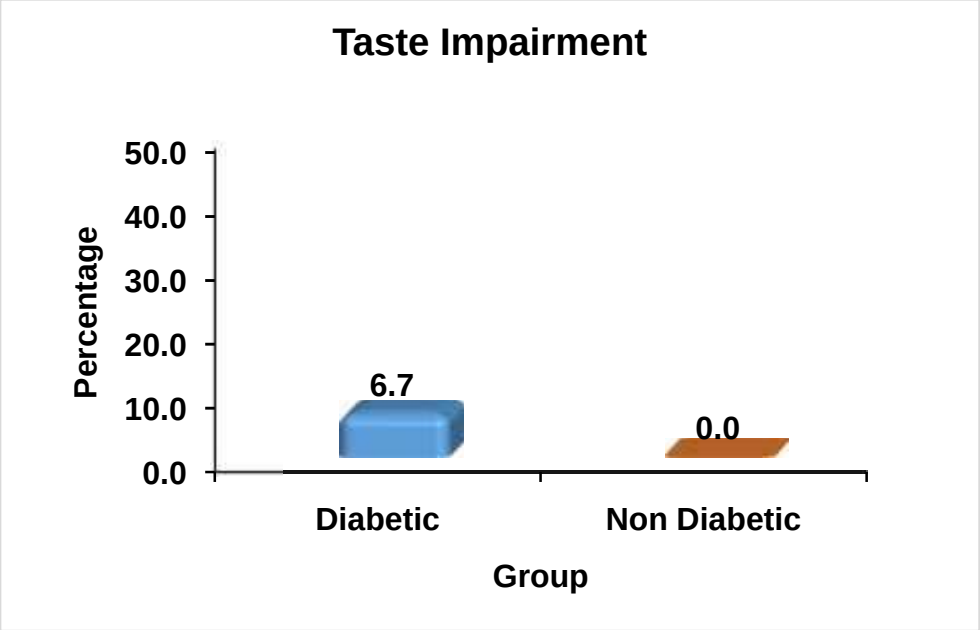

Figure 10: Taste impairment in diabetic and non-diabetic

Only 6.7% of diabetic patients experienced taste impairment and none in healthy(Table 15, Figure 10).

Table 16: Oral mucosal ulcer in diabetic and non-diabetic

Oral Mucosal Ulcer	Group					
	Diabetic		Non Diabetic		Total	
	N	%	N	%	N	%
Yes	1	6.7	2	13.3	3	10.0
No	14	93.3	13	86.7	27	90.0
Total	15	100.0	15	100.0	30	100.0

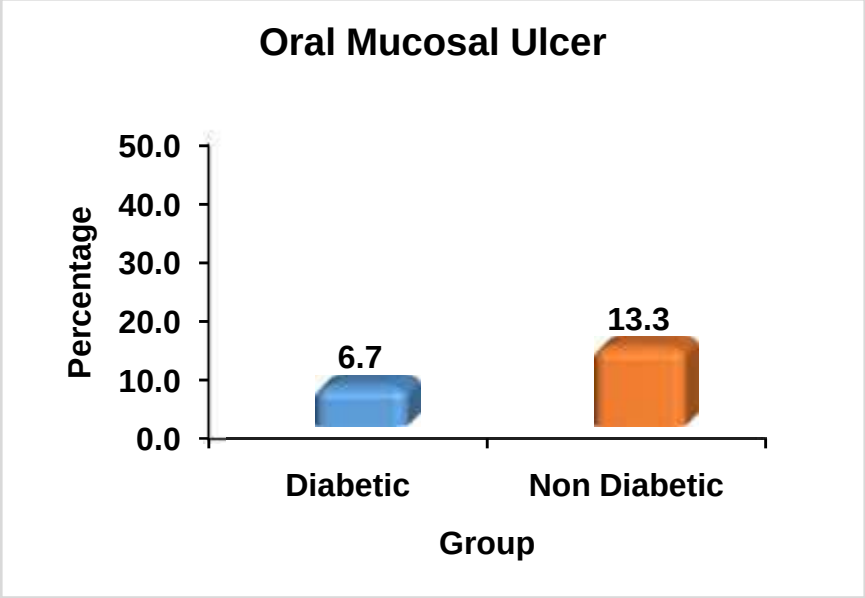

Figure 11: Oral mucosal ulcer in diabetic and non-diabetic

Surprisingly oral mucosal ulcers are more in non diabetic than diabetic that is 13.3% in non diabetic and 6.7% in diabetic (Table 16, Figure 11).

Discussion

Salivais a heterogeneous fluid consisting of proteins, glycoproteins, electrolytes, organic molecules, and also the compounds which are transported from the blood. Saliva constantly bathes the teeth and oral mucosa. saliva represents a mixture of all the secretions of both major i.e., parotid gland, submandibular gland and sublingual gland and minor salivary glands along with the gingival fluid. There are many biological factors in saliva which protects the enamel, dentin, and cementum from caries development and facilitate the remineralization.The ability of saliva to affect caries development is dependent on the quantity and composition of the secretion

In the present study it is reported that more than half of the diabetic patients are subjected to xerostomia. In the first minute the mean flow rate was surprisingly more in diabetic subjects than

that of the healthy subjects while other study outcomes were in contradiction to this finding, where as in the next four minutes the mean salivary flow was significantly more in healthy subjects than in diabetic subjects. It is observed that average mean salivary flow rate in healthy subjects are comparatively way higher than that of diabetic subjects which was consistent with other study findings(HakimehAhadian et al)[7]. The significant reduced salivary flow rate of diabetes is confirmed with the results of previous studies subjects (Kjellman 1970a: Conner et al. 1970)[8].

Diminished salivary flow rate can have deleterious effects on oral and systemic health(Navazesh et al., 1992a[9]; Atkinson and Wu, 1994[10]). Several studies reported that the unstimulated salivary flow rates in healthy individuals have found the average value which is about 0.3 ml/min. Value below 0.1ml/min are considered as hyposalivation and also values between 0.1-0.25ml/min(Tenovuo and Lagerlof, 1994)[11].It has been studied that there would not be any uniformly accepted reference values . The amount of saliva in the mouth changes within a person over time and individual (Ship et al., 1991)[12].

The affected salivary flow rate is mainly due to autonomic nerve dysfunction or microvascular changes which diminishes the ability of salivary gland to respond to hormonal stimuli[13]. Other causes are dehydration, side effects of drugs used by diabetic patients like diuretics, antihypertensive and antidepressents[14]. Lack of adequate salivary secretion leads to fungal infections like oral candidiasis and inadequate oral hygiene, discomfort in talking and swallowing food[15].

It was evident that all the diabetic subjects in this study developed dental caries which is closely associated with the hyposalivationwhich was also perceived in the study of(SadiaIqbal et al.,vol.31, no.1,june 2011)[16]. In addition to this periodontal disease was found as the mostcommon manifestation in the diabetic subjects followed by tooth loss, halitosis, glossitis, taste impairment, oral candidiasis and oral mucosal ulcer. this was in concordance with earlier literature(Sura A. A et al., Vol 3, No.2a,2015)[17] and also in other two studies(E Nandakumar et al[18]), (VaishnavisivakaliSubramanian et al[19]).

There are harmful effects of having a dry mouth, one of the study shows long term usage of biguanides drugs may decrease salivary flow rate[20].it is of extreme importance to keep saliva flowing as efficiently as possible. There are several ways to make this happen, and the most important is to increase the intake of liquids throughout the day. A dry mouth can sometimes be the first sign of dehydration, so drinking more water is the best way to fight the root cause, which increases the production of saliva, and a more provides balanced level of moisture in the mouth. Additionally, increasing the amount of fluids in the body can also help prevent ulcers and sores in the mouth and chapped lips. Severalstudies show that diabetics can fight dry mouth by drinking more liquids, but it is not a long term solution as once the body processed these fluids, the dry mouth again returns. When this happens, a more direct approach to the problem is needed. Fortunately, there are varioustreatmentto improve stimulate salivation, such as sugar-free gum, mouthwash, and mints. Some of therecent studies hasshown that drugs like Pilocarpine and Cevimeline has an effect of decreasing the sensation of oral dryness.

Conclusion

This study showed significant variation in salivary flow rates between diabetes and health emphasizing that most of the oral conditions are closely correlated to salivary secretion of the individual. This research was undertaken to increase the awareness of oral complications among diabetes and health. Of the oral manifestations screened, we found 100% positivity for dental caries followed by periodontitis. The data elicited from this study was restricted to the outpatient population visiting a medical hospital; a large scale study with screening for oral manifestations undertaken at various prominent hospitals in the metropolitan city would yield relevant epidemiological data.This study is a small step in the aforementioned direction.

Abstract

Introduction: Orthodontic appliances are meant for the correction of malocclusions. Placement of such appliances will necessitate a protracted period of 2 - 3 years wear. Neglect in maintenance of good oral hygiene may result in compromised periodontal health. Though many organisms in the mouth are found increased in their proportion during orthodontics, organisms like spirochetes, that grow well with simple source of nutrients, will flourishtoa larger extent.This preliminary study was undertaken to evaluate the prevalence of spirochete population in patients wearing orthodontic appliances by assessing the spirochetes load at different time intervals of treatment.

Reason: Spirochete is present in very small proportions, even in normal health mouth. In patients with poor oral hygiene and halitosis,thespirochetes has been demonstratedand found increased in its proportion, this is capable of deteriorating the oral health. Elimination of these organisms is a challenge.Studies have also revealed increased spirochete proportions in plaque samples from Orthodontic patients with poor oral hygiene.This study was conducted to analyse the time dependant changes in population of spirochetes in patients wearing orthodontic appliances. This will help to bring about awareness to the society about the importance of oral hygiene in orthodontic patients at all ages.

Materials and Methods: Inclusion criteria included a total of 10 participantsin the age of 20 - 35 years, who wererandomly selected,on the basis of willingness to participate in the study. Patients irregular for treatment and those with other systemic complications and periodontally compromised prior to commencement of Orthodontics were excluded from the study. Plaque

samples were collected from the participants at the 3rd, 6th or 9th month of treatment as T1, T2 and T3, respectively.

Result:The mean percentage value of spirochetes of the group with patients having the intra oral appliances for 3 months[T1] was 35.50%±25.544, T2 with appliance duration 6 months was 37.00%± 18.439and T3for 9 months was 57.50 % ± 22.267.

Conclusion: The study confirmedthat there is a statistically significant difference between spirochetes count found between 6 months and 9 months duration.[p =.023] On average, spirochetes count in 9 months was about 20.5% higher than spirochetes count in 6 months. It is concluded that, the increase in the duration of wear of the orthodontic appliance from 6 to 9 months proportionately increased the spirochete population from 37.00% to
57 .50% respectively.

Key Words: *appliances, plaque, microorganisms, orthodontics, spirochetes*

Introduction

Orthodontics is the science of dentistry that deals with the correction of malocclusion. The desired tooth movement is achieved by means of an orthodontic appliance that generates a force to bring about tooth movement for the correctionofmalocclusion.The treatment spans a duration of two to three years.The various mechanical components that constitute an orthodontic applianceincludesbrackets,buccaltubes,archwires, ligations made of stainless steel, nickel titanium, brackets, wires, springs and elastomeric components.This complex appliancesetup, predisposes to entrapment of food debris, and poses difficulty in cleaning,jeopardising the oral hygiene.Neglect of adequate oral health measures, can result in accumulation of plaque and colonisation with periodontopathicbacteriaresulting in gingival inflammation and bleeding [1] among orthodontic patients [2,3,4].

Compromised oral hygiene predisposes to white spot lesions,caries and periodontal diseases [5], and exposes to systemic complications.[6-10].Orthodontics was earlier done mostly for young children is now needed for adults too. The long duration of orthodontic appliance wear therefore, is likely to compromise on host response predisposing to periodontal diseaseamongorthodonticpatients.Studies using DNA probes have proven a close relationship betweenperiodontal disease and invasion of streptococci, lactobacilli and spirochetes in the subgingival plaque [11,12]

This increase in bacterial count in the plaque and tongue surface sometimes results in halitosis. [13,14,15]. These factors additionally can result in gingivitis, white spot lesion and caries when hygiene is neglected , contributing to complication of this treatment[16].

There are various organisms that colonise subgingivally in oral cavity like spirochaetes and fuseiform bacilli [17] .The streptococcus mutans and lactobacillus [18] are more responsible for caries and treponema are responsible for periodontal breakdown and halitosis during orthodontics. These microbes grow exclusively in conditions of poor hygiene. An orthodontic appliance affects the subgingival microbial composition, thereby increasing the prevalence of periopathogens

A preliminary study was thereforeundertaken to assess anaerobicspirochete levels in orthodontic patients presenting with normal oral health at different time intervals .The timedassessment of the spirochete count was conducted, on the third , sixthand ninth month of treatment .

Materials and Methods

This study was conducted to evaluate, the prevalence of oral treponema in patients having orthodontic appliances and presenting with normal oral health. The study design, a prospective longitudinal study, approved by the Institutional Ethical Committee, was conducted in patients attending the outpatient clinic of the Department of Orthodontics, Saveetha Dental College. The participants were under Orthodontic treatment with MBT .022 slot prescription, Abzil 3M conventional appliance.

Inclusion criteria included a total of 10 participantsin the age of 20 - 35 years, who wererandomly selected,on the basis of willingness to participate in the study. Patients irregular for treatment and those with other systemic complications andperiodontally compromised prior to commencement of Orthodontics were excluded from the study. Plaque samples were collected from the participants at the 3rd, 6th or 9th month of treatment as T1, T2 and T3, respectively

Sample collection

Participants were detailed about the study and the reason of this study. An informed consent was obtained. Soft plaque samples were collected under strict aseptic procedurewith sterile tooth pick from the tooth surfaces at 25, 26, 27, 35, 36 37 region. The plaque samples collected were immediately smeared on a clean glass slide and dried. These slides with smear were labelled and were rolled in a tissue paper and transported for microbial examination.

Microscopic Method

The smears were stained with simple staining method[19,20,21] with dilute carbolfuchsin for two minutes and washed in clean drinking water. The smears were then dried and examined under oil immersion objective of the microscope. In each smear more than 100 fields were examined.Each field was divided into a quarter and the investigator quantified the organisms based on their shape.

The study examined the total microbial elements present on the smear per field, and, the relative proportion of spirochetes were taken into consideration. A cumulative index of approximately 100 fields was figured out as percentage in relation to the other bacterial structures.Thepercentage of proportion of spirochetes was tabulated among each group separately.

Statistical Analysis

The relative proportion of spirochetes in most of the fields examined were noted and tabulated. Statistical analyses were performed including means and standard errors of the mean for each group. A value of $P<0.05$ was considered significant.

T2 & T3 – insignificant

T1 & T3 – insignificant

The mean percentage value of spirochetes of the group with patients having the intra oral appliances for 3 months[T1] was 35.50%±25.544, T2 with appliance duration 6 months was

37.00%± 18.439and T3for 9 months was 57.50 % ± 22.267. There is an increase in the proportion of the organism with increased duration of intra oral orthodontic appliance wear,more between 6 and 9 months than between 3 and 6 months.

From the paired samples t values it is inferred that there is a statistically significant difference between spirochetes count found between 6 months and 9 months duration.[p =.023] On average, spirochetes count in 9 months was about 20.5% higher than spirochetes count in 6 months. It is concluded that that, increase in the duration of wear of the orthodontic appliance from 6 to 9 months proportionately increased the spirochete population from 37.00% to
57.50%respectively.

Discussion

Severe crowding predisposes to poor oral health, attracting an increase in plaque deposition which can cause inflammation and gingivitis [22] that eventually leads to periodontitis and even bone loss.Orthodonticappliancespredisposes to periodontitis when hygiene is neglected.

The present study proved that increase in duration of treatment increases the population of spirochetes, in cases with neglected oral hygiene[Table 1]. The increase is statistically significant between 6 and 9 months. Statistical insignificance of the increase in spirochete population between T1 and T3 is probably because of the wide standard deviation, which is a reflection of the variation seen in the samples collected. The variations wherein, the spirochete count reduced in the 6th and 9th months in a few cases, was because some participants understood the implications of oral hygiene explained to them prior to their informed consent, and resorted to strict regimes of hygiene. The count was reduced in those participants after the initial sample.

Other studies have also recordedgradual increase in spirochetes population with increase in duration of the treatment, in patients who showed no improvement in oral hygiene[23]. This increase in spirochete population may be due to the fact that oral treponema are not obligate anaerobes and grow on simple source of nutrition.

BrekkEckley, 2012 [24]concludedthat plaque score and probing depths increased with successive orthodontic visits. This was attributed to an increase in the periodontopathogens, P gingivalis, T denticola, and T forsythia, particularly when hygiene was compromised . Additionally dark field microscopy in their study, confirmed an increase in the small and

large spirochetes population, non-motile rods, filaments and fusiforms, with a concomitant decrease inall coccoid forms and motile rods. The microbial profile contributes to the aggravated gingival inflammation, bleeding and increase in periodontal pocket depth in patients with compromised oral health.

The rough surface of the metallic component, the high surface tension of the various polymeric materials used and the complicated design of the appliance creates an environment for food stagnation and thereby biohostability of the appliance. Therefore an ideal appliance should be a poor biohost that will neither allow active growth of organism nor passively provide a media for multiplication of microorganisms which may be either chromogenic or that induces halitosis or interferes with the mechanical properties of the wires which could jeopardise orthodontic tooth movement [25].

The finding that the plaque score, probing depths returned to normalin thirty days post removal of the orthodontic appliance, reiterates the influence of these organisms during orthodontic therapy [24]. In spite of brushing twice a day patients under orthodontic treatment both adults and young children, are prone to poor oral hygiene [26], as mechanical restraints like bands, brackets and wires used in orthodontic appliances hinder cleaning of the debri and cause accumulation of plaque and microbial flora.

To prevent the plaque build up in orthodontic treatment the patient must be properly educated about the various techniques, and oral hygiene methods like brushing, flossing and rinsing [27,28,29], and the use of various prophylactic tooth pastes and mouth rinses.[30,31].

The present study therefore, highlights that maintenance of oral hygiene, is of paramount importance during orthodontic treatment, a very important message to be sent out to the society, particularly the aspirants of aesthetic correction of their malocclusion. Spirochetes classified as periodontopathogens are normal commensals found in small proportion in the oral cavity. The present study confirmed that with neglect in oral hygiene their proportions can increase, which is prone to pathogenecity.

Further studies, are required with greater sample size, to isolate the most prevalent pathogenic strains, to enable specific measures of their prevention in an Orthodontic patient.

Conclusion

There is an increase in the spirochete number,with increase in the duration of intra oral appliance.The mean percentage value of spirochetes at T1 at 3 months with orthodontic appliance was 35.50%, at T2 with appliance duration 6 months was 37.00%, and at T3 with

appliance for9months was 57.50%. Increase in spirochete count from 6 to 9 months showed a statistical significance.Neglect in oral hygiene during Orthodontics,can predispose to increase in spirochaete countin plaque samples, as the duration of treatment increases

Abstract

Introduction: Enterococci are Gram-positive facultative anaerobic bacteria which are normal commensals in the gastrointestinal tract, oral cavity, vagina etc [1].They are organisms of low virulence, but are known to cause various clinical infections that includes septicaemia, endocarditis, urinary tract infections, wound infections, and meningitis. Enterococci now rank among the top three-nosocomial bacterial pathogens, and strains resistant to currently available antibiotics, which pose real therapeutic difficulties [2] .Up to 90% of enterococcal infections in humans, are caused by Enterococcus faecalis

Aim and Objective: To detect the efaA (Endocarditis associated antigen) gene from Enterococcus faecalis isolated from patients with endodontic infections.

Materials and methods: A total of 20 isolates of Enterococcus faecalis were collected from patients undergoing endodontic infections. The samples were inoculated in Mac Conkey agar Brain infusion agar. Presumptive identification of Enterococcus was done by Gram's staining, Catalase test and heat tolerance test. DNA extraction was done. The amplificationof virulence genes was carried out. DNA analysis was done using PCR amplification.

Results: EfaA gene was detected in 3 out of 20 isolates.

Conclusion:E.faecalis though a commencal bacteria in Genito urinary tract it is gaining importance as in nosocomial pathogen and in endodontic infections. Within the limitations of this study it can be concluded that efaA, a potent *E. faecalis*virulence gene can be found in strains obtained endodontic infections.

Key Words: *Virulence factors, DNA extraction, Bacteraemia, Septicaemia, endocarditis*

Introduction

Enterococci are Gram-positive facultative anaerobic bacteria which are normal commensals in the gastrointestinal tract, oral cavity, vagina etc [1].They are organisms of low virulence, but are known to cause various clinical infections that includes septicaemia, endocarditis, urinary tract infections, wound infections, and meningitis. Enterococci now rank among the top three-nosocomial bacterial pathogens, and strains resistant to currently available antibiotics, which pose real therapeutic difficulties [2] .Up to 90% of enterococcal infections in humans, are caused by Enterococcus faecalis [3].

In the past few years, *Enterococcus faecalis* has been mentioned with increased frequency with regard to teeth with asymptomatic persistent endodontic infections, predominantly in therapy-resistant endodontic infection [4]. *E. faecalis* have been able to form biofilms in root canals, and this ability can be important for bacterial resistance and persistence after endodontic procedures [5]. There are studies that suggest that Enterococcus faecalis has the greatest potential to invade dentinal tubules and remain viable in themon comparison with S.mutans and S.gordonii which gives it the ability to cause chronic periapical disease and failure of endodontic treatment [5].

Besides this Enterococcus, faecalis have several virulence factors that promote a broad spectrum of events that allows disease development and progression. The infection was initiated as the bacteria binds to the ligands that are present at the site of infection after which the colonization can be accelerated through antibacterial attachment. They also modify the host's immune response. One important virulence factor is efaA [6].

E. faecalis endocarditis antigen (efaA) was first identified from the antiserum of a patient with *E. faecalis* endocarditis. The amino acid sequence of the associated protein efaA revealed 55–60% homology to a group of streptococci proteins known as adhesins. Hemolysin, gelatinase, ace, and ESP also function as putative virulence factors of endocarditis-causing *E. faecalis*. *E. faecalis* strains derived from different sources such as endocarditis, urinary tract infections, and even endodontic infections have been shown to possess distinct patterns of 'virulence factors' [7].Hence the aim of our study was to detect the presence of putative *E. faecalis* virulence factor efaA in root canals of therapy-resistant endodontic infections using the PCR method.

Materials and method

A total of 20 isolates of Enterococcus faecalis were collected from patients undergoing endodontic treatment. The samples were inoculated in Mac Conkey agar and Brain infusion agar. Presumptive identification of Enterococcus was done by Gram's stain, Catalase test and heat tolerance test. On Gram's staining Enterococcus are Gram positive cocci arranged in pairs, on catalyst test they are Catalase negative and in heat tolerance test that tolerate the temperature of 60 degrees C for 30 minutes. On mac Conkey agar they showed small lactose fermenting colonies.

DNA Extraction

Genomic DNA used as template for polymerase chain reaction (PCR) amplification was prepared using conventional phenol-chloroform DNA extraction method.

Amplification

The amplification of virulence genes was carried out as follows: Initial denaturation at 95°C for 15 min followed by denaturation at 94°C for 1 min, annealing at 56°C for 1 min, and extension at 72°C for 1 min.

The Polymerase Chain Reaction amplification of the efaA gene was carried out as follows: Predenaturation at 95°C for 4 min followed by denaturation at 95°C for 30 cycles of 30 s each; 1 min for annealing at 52°C and elongation at 72°C for 1 min. Both positive control and negative control, consisting solely of the PCR reaction mixture without DNA template were included to check the validity of the technique utilized.

DNA Analysis

Twenty-five microliters of respective amplified products were loaded into the wells and electrophoresed at a constant current of 50V for about 45 min using 1.5% agarose gel. A 100 bp DNA ladder marker was included as the standard molecular weight marker. The electrophoresed gel was later subjected to ethidium bromide staining and photographed under UV transillumination

Result

EfaA gene was detected in 3 out of 20 isolates.

Discussion

Enterococci are gram positive cocci that can occur singly, in pairs or as short chains. They are facultative anaerobes, possessing the ability to grow in the presence or absence of oxygen. Enterococci can withstand harsh environmental conditions [8]. Enterococci can grow at 10 degree Celsius and 45 degree Celsius, at pH 9.6, in 65% Nacl broth and survive at 60 degree Celsius for 30 minutes. E faecalis can adapt to adverse conditions [9].

There are currently 23 enterococci species and they are divided into five groups based on their interaction with mannitol, sorbose and arginine.*E. faecalis* can survive extreme

challenges. Its pathogenicity ranges from life-threatening diseases in compromised individuals such as bacteraemia,septicaemia, endocarditis, and urinary tract infections to less severe conditions, such as infection of obturated root canals with chronic apical periodontitis.The persistence of E.faecalis might be due to the virulence factors ace and esp.Virulence factors of *E. faecalis* enable adherence to host tissue, invasion and modulation of host inflammatory response, and secretion of various products which enhance biofilm formation [10].

Serum plays an important role in the invasion. The expression of virulence factor efaA is expressed when E.faecalis is grown in a medium that contains serum [11].The extra cellular matrix of our tissue consists of glycoproteins like collagen, laminin, fibronectin and proteoglycans.These can be exploited by micro-organisms for colonization and initiation.The ability of a microorganism to adhere to collagen play an important role in the pathogenesis of endocarditis [12]. The dentinal tissue and the heart tissues share common proteins, it is believed that efaA should be facilitated through bacterial adhesion to collagen and extracellular matrix relevant in endodontic infections [13].

About 3 out of 20 (almost 15%) isolates were detected with efaA gene. E faecalis have been able to form biofilms in root canals and this ability can be important for bacterial resistance and persistence after endodontic procedures.

A similar recent molecular-based study by Randa Salah indicated that virulence determinants endocarditis antigen (efaA) genes and ace genes has been found in *E. faecalis* isolates of oral rinse samples of patients suffering from dental diseases[14].

In a study conducted by Creti *et al*. showed that E.faecalis strains derived from different sources such as endocarditis, urinary tract infections possessed distinct patterns of virulence factors ace, efaA, and gel genes. These were found to be the most common virulence factors.

Thomas Preethee conducted a study in which 32 contaminated root canal samples were analysed in which 15 of them were positive for E.faecalis. Out of the 15 positive samples, efaA gene was identified in 11 samples (almost 73%) [15]. Bittencourt de Marques observed that the efaA gene is frequently associated with ESP or eep (enhanced expression of pheromone) and to a lesser extent with virulence markers aggA (aggregation substance gene) [16].

Although molecular based identification methods are designed to detect molecular DNA, a limitation of this method is that it cannot distinguish between DNA from viable and dead cells and it’s unclear whether the results from PCR methods represent the living flora or rather a record of an organism that have entered but not survived in the canal [17 -20].

Conclusion

E.faecalis though a commencal bacteria in Genito urinary tract it is gaining importance as in nosocomial pathogen and in endodontic infections. Within the limitations of this study it can be concludedthat efaA, a potent *E. faecalis*virulence gene can be found in strains obtained endodontic infections. Hence this virulence gene can be correlated with the pathogenicity of E.faecalis.Further studies should aim at obtaining blood samples from patients immediately after endodontic retreatment procedure to analyse the role of the efaA gene in causing bacteremia.

Abstract

Introduction:PVL and γ -haemolysin are considered to be members of a toxin family known as synergohymenotropic toxins, as they act on cell membranes by the synergy of two proteins that form a pore. Only 2% of S. aureus isolates produce PVL, while γ -haemolysin is produced by more than 99% of S. aureus isolates. PVL is the most leukocytolytic toxin in the family, however it does not exhibits no haemolytic activity on human erythrocytes. A sum of 20 clinical isolates of S. aureus were subjected to antibiotic sensitivity pattern followed by the detection of pvl gene by PCR. We have observed increased resistance to most of the routinely used antibiotics and 10% of our isolates found to have pvl gene. As this gene is directly associated with skin and soft tissue infections by S. aureus, our two isolates may even cause such infections, although none of these strains were not obtained from cutaneous lesions. Panton–Valentine leukocidin (PVL) is one of many toxins associated with S. aureus infection. Because it can be found in virtually all CA-MRSA strains that cause soft-tissue infections, it was long described as a key virulence factor, allowing the bacteria to target and kill specific white blood cells known as neutrophils. This view was challenged, however, when it was shown that removal of PVL from the two major epidemic CA-MRSA strains resulted in no loss of infectivity or destruction of neutrophils in a mouse model.

Materials and Method: These antibiotics were procured from Himedia, Mumbai. This was performed by Kirby-bauer disc diffusion method as per CLSI guidelines.

Result: We have observed a varied pattern of sensitivity among one *S.aureus*isolates. There was complete resistance observed for penicillin(100%), 9/20(45%)isolates were shown to the resistant to erythromycin,6/20(30%) were to cotrimoxazole,4/20(20%)were to linezolid followed by 3/20(15%) were resistant to ciprofloxacin and clindamycin

Conclusion: The pathogenicity of *Staphylococcus aureus* depends on various bacterial surface components and extracellular proteins.uggests that the Panton-Valentine leukocidin (PVL) is 1 such virulence factor that has a major role in pathogenicity.

Key Words: *Staphylococcus aureus, Pvl gene, PCR, Leukocidin ,Haemolysin.*

Introduction

Staphylococcus aureus is an important human pathogen that causes a wide range of diseases from mild superficial skin infection to life-threatening bacteremia and infective endocarditis, as well as toxin-mediated conditions such as toxic shock syndrome.[1] They produce more than 30 different extracellular products.[2]Nearly all strains exhibit a group of enzymes and cytotoxinsthat includes haemolysins (α, β, γ and δ), nucleases, proteases, lipases, hyaluronidase and collagenase. Some strains produce one or more additional exoproteins, which include toxic shock syndrome toxin-1 (TSST-1), the staphylococcal enterotoxins (SEA-E, G-I), the exfoliative toxins (ETA and ETB) and Panton–Valentine leukocidin (PVL) [3].

Two major mechanisms of eukaryotic cell death have been identified, namely necrosis and apoptosis. Necrotic cell death has classically been considered as a passive process resulting from physical or chemical injury. In contrast, cells undergoing apoptosis play an active role in their own demise: extracellular stimuli or genetic programming activates a cascade of intracellular

events resulting in morphological and biochemical alterations. Apoptosis has already been described in monocytes and PMNs exposed to S. aureus α-toxin and Fusobacterium necrophorum leukotoxin, respectively (15, 16). PVL-sensitive target cells, including PMNs, macrophages, and the promyelocytic cell line HL-60 (8, 17, 18) are thought to undergo osmotic lysis secondary to pore formation in the cell membrane. This process would be consistent with necrosis.

Although PVL has potent membrane-disturbing and cytolytic activities in vitro, the mechanisms by which it exerts its lethal effects on target cells, particularly on the first line of host defense cells such as neutrophils, and the sequence of events in the overall cytotoxicity are not known. Furthermore, in other clinical situations such as fulminant hepatitis (19), the apparent predominance of necrosis has been shown to be actually secondary to apoptosis. Hence, the mechanisms by which PVL causes injury to host tissues and potentially to peripheral blood cells during the course of infection are not clearly established, and the role of necrosis versus apoptosis in the pathogenesis of PVL-associated infections remains to be defined. The focus of the present study was to characterize the biological effects of S. aureus PVL on human peripheral PMNs in relation to the possible involvement of this toxin in necrotizing pneumonia pathogenesis.

Apoptosis was only triggered at low PVL concentrations, whereas higher concentrations induced necrotic alterations. These different actions may be related to the molecular properties of PVL. At low concentrations, PVL, which binds to specific but unidentified cell surface receptors (17), could produce small numbers of octameric pores (9). These pores could favor the entry of other PVL molecules into the cell, allowing the toxin to act on mitochondria and induce apoptosis. However, at high concentrations (200 nM), PVL may nonspecifically adsorb to the lipid bilayer, forming larger pores that are Ca2+ permissive, forming more numerous octameric pores, or leading to Ca2+ channel opening (36), all of which can result in necrosis. Moreover, larger pores would also lead to a loss of ATP, which is required for most apoptotic processes (37, 38). Thus, the modes of cell death in vivo (necrosis versus apoptosis) may critically depend of the PVL concentration. In staphylococcal infection, cells of the host tissue surrounding the bacteria are

likely to be exposed to a PVL concentration gradient: necrosis would occur locally, while apoptosis would occur in the periphery and even in circulating blood cells.

In previous study, the population structure of S. aureus, isolated from the nares of healthy persons in the Rotterdam area, the Netherlands, was elucidated (8). Strains were obtained from healthy children (<19 years) and elderly persons (>55 years). Invasive strains (blood culture, skin and soft tissue infections, and impetigo isolates) were included in this study (Table). All carriage and clinical isolates (n = 1,033) were mecA negative. We used the same strain collection to study the PVL prevalence in carriage and invasive isolates of S. aureus from a single geographic region.

Detection of PVL gene in Staphylococcus aureus

Staphylococcus aureus isolates were detected for the presence of *pvl*gene by PCR analysis. Detection of the gene was carried out using primer as depicted in table 1. Bacterial DNA was extracted by boiling lysis method. 1 µL of DNA extract was used as template for PCR reaction. The reaction mixture contained 2mM of $Mgcl_2$ 0.2mM dNTP mix and 0.8µM of *pvl*gene with IU of Taq polymerase (New England Biolabs) in a 1x PCR buffered reaction. A positive control of S. aureus with *pvl* gene was also included in this study. PCR amplification was carried out using thermal cycler (Eppendorf) with the following cycling condition. Initial denaturation at 96^{o}C for 2 min and 30 cycles for 30s, 52^{o}C for 60s and 73^{o} C for 30s, followed by a final extension of 6 min at 72^{o}C. PCR products were resolved in 1.5% agarose gel. A 100bp ladder was including in all the gel analysis.[8]

Discussion:

S. aureus is one of the most common Gram-positive bacterial pathogens in humans. It is an opportunistic pathogen that colonizes the skin of approximately 20% of the population without causing clinical symptoms (22, 23). However, breached mucocutaneous membranes or impaired host immunity facilitate tissue invasion and bloodstream dissemination of S. aureus (24). This bacterium can cause serious infections often associated with abscess formation such as osteomyelitis, endocarditis, and pneumonia that often require a prolonged and aggressive antibiotic treatment. Among the most serious complications of S. aureus infections are manifestations of septic and toxic shock syndromes that may lead to multiple organ failure (25). We recently described a novel clinical entity, S. aureus necrotizing pneumonia, which is associated with a massive cell lysis of host pulmonary tissue and is highly lethal in young immunocompetent patients (1). We also found that these cases were strongly associated with S. aureus strains producing the otherwise very infrequent exotoxin PVL (1). In the present report, we demonstrated that PVL is a remarkable bacterial virulence factor because this toxin is localized in the pulmonary lesions of patients who died from necrotizing pneumonia and induces PMN apoptosis by directly targeting mitochondria.

Staphylococcal infections are typically associated with tissue death. Induction of apoptosis by S. aureus may cause tissue damage, compromise the antimicrobial immune response, and thereby

facilitate bacterial spread. S. aureus can induce apoptosis of epithelial cells (26–28), endothelial cells (29–31), keratinocytes (32), osteoblasts (33), lymphocytes, and macrophages (34). In epithelial cells, keratinocytes, or osteoblasts, S. aureus–induced apoptosis may require internalization of the bacteria (26, 27, 30, 32, 33). Conversely, Bantel et al. (16) showed that S. aureus α-toxin does not require bacterial internalization to induce apoptosis. Similarly, our data indicate that bacterial invasion of PMNs is not required for PVL to induce apoptosis. Hence, soluble PVL can be regarded as a mediator of S. aureus–induced neutrophil apoptosis, depleting neutrophils available for phagocytosis. Neutrophils transit through the human circulation en route to tissues, where they form the first line of cellular defense against invading bacterial pathogens. Phagocytosis of complement-opsonized targets is a primary function of neutrophils at sites of inflammation, and clearance, by apoptosis, of PMNs that have phagocytosed microbes is important for the resolution of inflammation (35). By inhibiting neutrophil phagocytosis, PVL could enhance the pathogenicity of S. aureus. Neutropenia is significantly more frequent in patients with necrotizing pneumonia caused by PVL-positive S. aureus than in patients with pneumonia caused by PVL-negative S. aureus (1) and could be due to the presence of PVL in pulmonary endothelial cells. Circulating PMNs could encounter PVL during their passage into the pulmonary vessels and therefore enter the cascade that leads to their apoptosis. As the cellular systems used in this study may not accurately reflect host-pathogen interactions in vivo, we cannot exclude the possibility that other staphylococcal exoproteins might contribute to human cell death.

In the present study, we have detected pvl gene in 2/20 (10%) of our S. aureus isolates. Similar kind of study conducted by Johnsson and colleagues in 2004 reported PVL gene was detected in one out of 65 S. aureus isolates collected prospectively from septicaemic patients.[9] This finding was in agreement with our study and other previous studies showing prevalences of 0–2% in positive blood cultures.[10] In addition, none of the S. aureus isolates causing infective endocarditis was PVL-positive.[11]Thus, PVL does not seem to represent an important virulence factor in invasive bloodstream infections. Our isolates were not collected from skin and soft tissue related infection, even though, two strains were showed positive for this gene. In cutaneous infections, PVL has been associated more frequently with direct invasion and tissue

destruction (e.g., necrotising primary skin infections such as furunculosis) than with secondary infections after skin injury. he Staphylococcus aureus Panton-Valentine leukocidin (PVL) is a pore-forming toxin secreted by strains epidemiologically associated with the current outbreak of community-associated methicillin-resistant Staphylococcus aureus (CA-MRSA) and with the often-lethal necrotizing pneumonia. To investigate the role of PVL in pulmonary disease, we tested the pathogenicity of clinical isolates, isogenic PVL-negative and PVL-positive S. aureus strains, as well as purified PVL, in a mouse acute pneumonia model.

Isolates categorized by type of staphylococcal infection revealed that PVL positive isolates were strongly associated with superficial abscesses and other skin and soft tissue infections, whereas the association of the PVL positive isolates with bone and joint infections was low. These results confirm reports from previous studies where it was detected that 93% of PVL positive S. aureus isolates were associated with furunculosis and other skin and soft tissue infections [6]. The current study and recent reports from Europe demonstrate that PVL positive methicilin susceptible S. aureus has emerged as a significant cause of skin and soft tissue infections and invasive infections such as necrotising pneumonia, soft tissues necrosis [24-26]. Alhough PVL positive S. aureus are often associated with fatal necrotising pneumonia cases in the present study there were only two PVL positive MSSA caused pneumonia cases with positve outcome.

PVLpositive S. aureus is isolated rarely from cases of folliculitis or impetigo. PVL and γ -haemolysin are considered to be members of a toxin family known as synergohymenotropic toxins, as they act on cell membranes by the synergy of two proteins that form a pore. Only 2% of S. aureus isolates produce PVL, while γ -haemolysin is produced by more than 99% of S. aureus isolates. [4]Pvlis the most leukocytolytic toxin in the family, however it does not exhibits no haemolytic activity on human erythrocytes.[5] It also dermo-necrotic, as observed after .intradermal injection of rabbit skin. [6] At sub-lytic concentrations, PVL has been demonstrated to induce granule secretion and release of leukotriene B4 and interleukin-8 from human polymorphonuclear leukocytes.[6] Based on this background, we have undertaken this study to detect the presence of pvl gene among S. aureus by PCR. In 1932, Panton and Valentine described PVL as a virulence factor belonging to the family of synergohymenotropic toxins (4).

These toxins form pores in the membrane of host defense cells by synergistic action of 2 secretory proteins, designated LukS-PV and LukF-PV, which are encoded by 2 cotranscribed genes of a prophage integrated in the S. aureus chromosome (5). PVL is mostly associated with community-acquired methicillin-resistant S. aureus (MRSA) infections and distinguishable from nosocomial MRSA by nonmultidrug resistance and carriage of the type IV staphylococcal chromosome cassette element .

Conclusion:

In our study, we have seen only 10% of them were found to harbor pvl gene. As this gene is directly associated with skin and soft tissue infections by S. aureus, our two isolates may even cause such infections, although none of these strains were not obtained from cutaneous lesions. In order to prove its virulence, it is necessary to include more samples especially from cutaneous lesions.

Abstract

Background: Determination of sex is an essential criteria, for the identification of an individual.In number of civil and criminal matters identification of the individual, either living or dead, is needed. The anatomical and medical features are the two major characters to constitute the identity. The establishment of identity is required from fresh intact corpses, decomposed corpses, mutilated and dismembered corpses or skeletalised material

Aim: The aim of the research was to measure the height and width of mastoid process and distance between the asterion to tip of the mastoid process for the determination of sex.

Objective: In this research the measuring of height,width of mastoid process and distance between the asterion to tip of the mastoid process in the dry skulls of South Indian adults was focused.The measurement of mastoid process will differ in male and female.since it is different,the measurement is useful in anthropology and also in forensic studies.

Materials and Method: The collection of 30 human dry skulls and measuring the height,length and width of mastoid process for the sex determination.Determining the sex of human skeletal remains using the skull is important to the disciplines of human osteology, forensic anthropology, paleopathology,paleodemography for examination and diagnosis.

Result: 30 skulls are used for this study.In that 14 Skulls are identified as female skull and remaining 16 skulls are identified as male skull by measuring the area of a mastoid triangle by using heron's formula.The mastoid process is lengthier in males than in females.

Conclusion: Sex could be determined very well from the cranium using Anthropometry.Parameters like mastoid process length can be used as a good index for the determination of sex.From the present study conducted on 30 dry skulls it is concluded that mastoid length is a reliable indicator for sexual dimorphism in mastoid process of skulls. The result of this study offering a good opportunity to identify the sex using the mastoid process. The length of the mastoid process is higher in males than females.

KeyWords*:Mastoidprocess,Mastoidtriangle,asterion,porion,mastoidale,Heron'sformula,sexdifferentiation,Forsenic studies.*

Introduction

Determination of sex is an essential criteria, for the identification of an individual.In number of civil and criminal matters identification of the individual, either living or dead, is needed. The anatomical and medical features are the two major characters to constitute the identity. The establishment of identity is required from fresh intact corpses, decomposed corpses, mutilated and dismembered corpses or skeletalised material [2]. Sex determination of human or human skeletal remains is considered vital step in identification and is crucial for further analysis.Skull and pelvis assume great importance in establishing sex of an individual.The sex is best assessed from pelvis but it is very often damaged in case of decomposition,fire accidents,etc.,The second best area for the identification of sex is the skull.Krogman [21] states that skull is the most dimorphic and easily sexed portion of skeleton after pelvis, providing up to 92% reliability. Bass [22] states that the skull probably is the second best area of the skeleton to use for determining sex. Bass [22], Byers [23] and Pickering and Bachman [24] presented the idea that skull is the second best choice to estimate the sex of the dead body.Thefeatures in the skull, that helps in the sex determination includes general appearance,supra orbital ridges,glabella,zygomaticarches,mastoidprocesses,external occipital protuberance,mandible and palate.

The mastoid process characteristics has a greater utility in the determination of sex.It is a pyramidal shaped projection in the temporal bone situated behind the ear on each side(1). If the pelvis is absent in accidental cases,it is difficult to identify the gender of a human .In such cases,the mastoid process is used to determine the sex by measuring the mastoid triangle because the length varies in both the male and female.It is situated behind the external auditory meatus and lateral to styloid process [1].The mastoid process is sexually dimorphism has been affirmed non- metrically by Hoshi [18],Larnach and Macintosh [19] and metrically by Saavedradepaiva and sagre [1].Mastoid region is one of the regions with most dimorphic traits. The tip of mastoid process is sexually dimorphic. It tend to be vertical in male and pointed inwards in females [25].

Surface

A sex differentiation in the mastoid process is made by calculating the area of mastoid triangle which is a technique reported by Paiva and Segre [20].This technique involves the measurement of the distance between the three triangular points(Asterion,Porion and Mastoidale).

Asterion- Meeting point of lambdoid,occipitomastoid and parietomastoid sutures.
Mastoidale-Tip of the mastoid process.
Porion -The uppermost lateral point of external auditory meatus.

Calculating the area of the triangle and then adding the right and left areas of the triangle gives a value which is used to identify the sex which is calculated by using heron's formula.The value is higher in males when compared to females.This method of sex differentiation is useful in forensic studies.

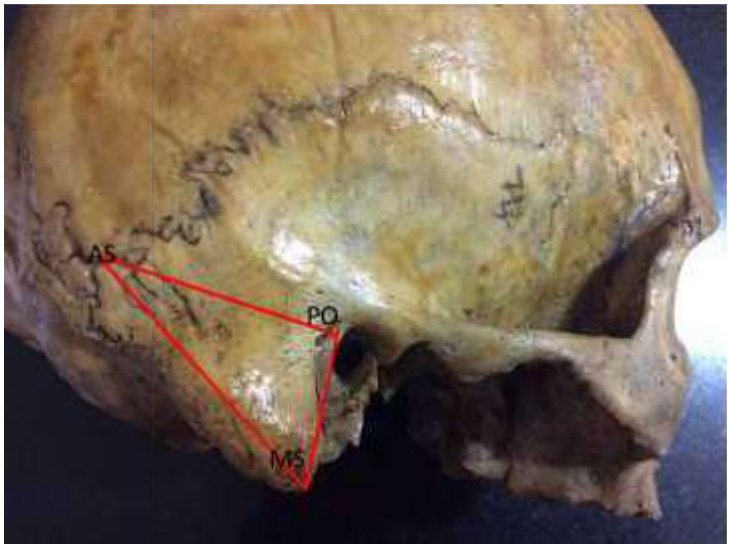
Materials and Methods

The study sample was taken from the Department of Anatomy,Saveetha dental college,SaveethaUniversity,Chennai,TamilNadu,India which represents the south Indian population.A total of 30 skulls were selected for the study.Three points (Asterion (As),Porion (Po) and Mastoidale(Ms)which forms the mastoid triangle were marked.The measurements are made by using the verniercalliper (0.01mm) between asterion to mastoidale,mastoidale to Porion and asterion to porion.The area of the triangle was calculated by the Heron's formula with the three sides a,b&c.

A=square root of s(s-a)(s-b)(s-c)

If the value of the total area is greater than or equal to1447.60mm2 ,it denotes the male skull or if the value is less than or equal to 1260.70mm2.

Figure 1: Shows Mastoid Triangle



Result

30 skulls are used for this study.In that 14 Skulls are identified as female skull and remaining 16 skulls are identified as male skull by measuring the area of a mastoid triangle by using heron's formula.The mastoid process is lengthier in males than in females.

Table-1: Shows values after measuring mastoid angle using Herons formula

	N	Range	Minimum	Maximum	Mean	Std. Deviation
LENGTH BETWEEN ASTERION AND MASTOIDALE .Right	30	21.0	35.0	56.0	45.630	5.2261
LENGTH BETWEEN ASTERION AND MASTOIDALE .Left	30	21.1	34.8	55.9	44.497	5.1854
LENGTH BETWEEN ASTERION AND PORION. Right	30	23.7	27.8	51.4	40.938	5.2963
LENGTH BETWEEN ASTERION AND PORION. Left	30	24.9	25.7	50.5	40.453	5.7737
LENGTH BETWEEN PORION AND MASTOIDALE. Right	30	17.5	13.9	31.4	23.289	4.5257
LENGTH BETWEEN PORION AND MASTOIDALE. Left	30	17.2	14.7	31.9	23.017	4.1514

Discussion

The determination of mastoid triangleis important in sexing the individuals.This is the most damaging part during the skull damage.This study involves the measurement of mastoid

process by using heron's formula.The area for mastoid triangle is calculated for each skull.According to the study by Paiva and Segre, male triangle area was significantly greater than female triangle area. Values calculated according to their study mean values was : in female : 570.9 mm2 and 575.1 mm2 in right and left sides. In male : 723.9 mm2 and 731.2 mm2 in right and left sides(1).One of the previous studies results shows male right :663.66mm2 ,male left : 662.54 mm2, female right : 595.92 mm2, female left : 589.29mm2 was found [20].

In this study,the value of the total area is greater than or equal to 1447.60mm2 ,it denotes the male skull or if the value is less than or equal to 1260.70mm2, denotes a female skull.In this study 14 skulls have a value less than 1260.70mm2 and 16 skulls have a value above 1447.60mm2.One of the defect of this technique is its use in sexing individual skulls and also due to asterion point localization, which position changes during the course of life [1].Other studies are done by using the known skulls(i.e.,by knowing whether skull is male or female).But this present study was done by using the unknown skulls (i.e.,without knowing the sex of the skull).

One of the previous studies suggests that, when skulls were placed on at surface, the male skulls rest on the mastoid processes while female skulls on occipital condyles or other portions of the skull. This observation indirectly indicates that males skulls have more mastoid length as compared to female skulls, that is why, male skulls rest on mastoid processes but not female skulls [3].

Area values are compared between present study and reference study which are depicted in the Table-2.

Table-2 depicts the difference in total area of males and females between present study and one of the reference studies

SEX	TOTAL AREA	
	Presentstudy	Reference study
Male	1492.62mm2	1461.06mm2
Female	1243.81mm2	1222.79mm2

Conclusion

Sex could be determined very well from the cranium using Anthropometry.Parameters like mastoid process length can be used as a good index for the determination of sex.From the present study conducted on 30 dry skulls it is concluded that mastoid length is a reliable indicator for sexual dimorphism in mastoid process of skulls. The result of this study offering a good opportunity to identify the sex using the mastoid process. The length of the mastoid process is higher in males than females.

Dysmenorrhea in Women

Harini. N.S[1], Gowri Sethu[2], Sankari.M[3]

Graduate student[1], Professor [2],Department of Physiology,

Professor[3], Department of Periodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Dysmenorrhea is a common menstrual complaint with a major impact on women's quality of life, work productivity, and health-care utilization. The prevalence of dysmenorrhea varies between 16% and 91% in women of reproductive age, with severe pain in 2%–29% of the women studied. Women's age, parity, and use of oral contraceptives were inversely associated with dysmenorrhea, and high stress increased the risk of dysmenorrhea. Inconclusive evidence was found for modifiable factors such as cigarette smoking, diet, obesity, depression, and abuse. Dysmenorrhea is a significant symptom for a large proportion of women of reproductive age; however, severe pain limiting daily activities is less common.

Aim: The main aim of this review article is to know in detail about Dysmenorrhea in Women.

Objective: The objective of this article is to know about dysmenorrhea in women, what is the cause, what are the consequences and why is it happening and also to know about dysmenorrhea in all aspects and to know the opinions from different authors.

Materials and Methods: The present study was to know about Dysmenorrhea in women. Various articles from different authors were collected and summed up as a review article so that Dysmenorrhea in women is known elaborately in all aspects.

Conclusion: In conclusion, this review shows that dysmenorrhea is a significant symptom for a large proportion of women throughout the reproductive years. Severe dysmenorrhea limiting daily activities is much less common. Improvement of the symptom over time has been observed, although many women also experience unchanged or worse symptoms. Dysmenorrhea is inversely related to age, parity or number of live births and oral contraception us. Dysmenorrhea is positively associated with stress related to both work and general life, as well as with family history of dysmenorrhea.

Keywords: *Dysmenorrhea, women, menstruation, painful periods, abdomen.*

Introduction

Dysmenorrhea or painful menstruation is defined as a severe, painful, cramping sensation in the lower abdomen that is often accompanied by other symptoms, such as sweating, headaches, nausea, vomiting, diarrhoea, and tremulousness, all occurring just before or during the menses [1]. There are 2 types of dysmenorrhea: Primary dysmenorrhea refers to pain with no obvious pathological pelvic disease and almost always first occurs in women 20 years or younger after their ovulatory cycles become established [1]. Secondary dysmenorrhea is caused by underlying pelvic conditions or pathology and is more common in women older than 20 years [1, 2].

Dysmenorrhea is considered the most common symptom of all menstrual complaints and poses a greater burden of disease than any other gynecological complaint in developing countries [3]. Among women of reproductive age worldwide, dysmenorrhea is more prevalent than the other 2 common types of chronic pelvic pain, namely, dyspareunia and noncyclical chronic pelvic pain [4]. Being a debilitating condition for many women, it has a major impact on health-related quality of life, work productivity, and health-care utilization [5–9]. As a result, dysmenorrhea is responsible for considerable economic losses due to the costs of medications, medical care, and decreased productivity [1]. The prevalence of dysmenorrhea reported in the literature varies substantially. A greater prevalence was generally observed in young women, with estimates ranging from 67% to 90% for those aged 17–24 years [10, 11].

A recent large Australian study of senior high school girls found that a higher proportion, 93%, of teenagers reported menstrual pain [12]. The studies in adult women are less consistent in reporting prevalence of dysmenorrhea and often focus on a specific group, with rates varying from 15% to 75% [10]. Severe pain sufficient to limit daily activities is considerably less common, affecting approximately 7%–15% of women [10], although a study of adolescents and young adults aged 26 years or less reported that 41% of the participants had limitations in their daily activities due to dysmenorrhea [7].

A range of risk factors for dysmenorrhea have been identified in the literature, although mixed results have been observed for many of these factors. In general, increased severity of dysmenorrhea has been suggested to relate to age [13–15], smoking [14, 16, 17], higher body mass index [18], earlier age at menarche [15, 18], nulliparity [15, 19], longer and heavier menstrual flow [15, 18], and family history of dysmenorrhea [20]. Women using oral contraceptives generally report less severe dysmenorrhea [14, 15, and 21]. Depression and stress have also been shown to increase the risk of dysmenorrhea [9, 22]. Other common factors, such as education [23], marital status [14], employment [19], alcohol consumption [17, 18], and physical activity [15, 18], show largely negative or inconclusive results.

Material and Methods

The present study was to know about Dysmenorrhea in detail. Various articles from different authors were collected and summed up as a review article so that dental crowding is known elaborately in all aspects. The articles were collected by manual searching of the references of the relevant retrieved articles, peer-reviewed physiologic journals, and gray literature. Search terms included dysmenorrhea, menstruation, women, painful periods. Non-English articles were excluded from the review in the study-selection stage. Data extraction and evaluation of primary studies were performed independently by 2 reviewers.

Discussion

Knowledge of physiology of reproduction is important for teenage girls to practice menstrual hygiene [47]. Dysmenorrhoea is a common distressing disorder in women that manifests during menstrual phase especially in young females [51]. Primary dysmenorrhea is a medical condition

of pain which is worst during first day of menstruation that interferes with daily activities. It is not associated with any pathological changes.[48]. Dysmenorrhea is defined as painful menstrual cramps of uterine origin. It is the common gynecological condition that can affect as many as 50% of women. [49].

Dysmenorrhea is one of the most common gynecological problems among female students, which may be the leading cause of absenteeism from college. Dysmenorrhea is of two types. The primary is a menstrual pain without any organic pathology. When the pelvic pain is associated with identifiable pathological conditions, it is called secondary. Dysmenorrhea also may be due to anxiety, emotional instability, a faulty outlook on sex and menstruation, or imitation of the mother's feelings about menstruation. Researchers reported that excessive production of prostaglandins, which causes severe uterine contractions, which cause pain and decrease blood flow and oxygen to the uterus. Similar to labour pains, these contractions can cause significant pain and discomfort. Prostaglandins may also contribute to nausea and diarrhoea. [49].

Most studies show that dysmenorrhea is a common problem affecting the majority of women in the community. Severe pain or pain limiting women's daily activities, however, occurred only in 2%–28% of adult women. Self-medication is a worldwide problem and it is common in developing countries like India every day, everywhere, consumers reach for self-care products to help them through their common health problems.[50] The lowest rate of 2% reported in a longitudinal study was possibly due to potential underreporting as 74% of the included women were employed and thus less likely to stay in bed and miss work, which is used to define severe pain in the study [37]. The prevalence of severe pain reported in this review appears to be higher than the 12%–14% reported in community-based studies in the World Health Organization review [4] but comparable with 5%–20% reported in another review of the condition in developing countries [38].

Weissman [37] found that dysmenorrhea persisted over the 6-year follow-up among the majority of women reporting it at baseline, and improvement or worsening of the symptom was equally likely. In their multivariable analysis, the presence of dysmenorrhea at baseline [excluding

women with severe dysmenorrhea] was a strong predictor of reporting moderate or severe dysmenorrhea at follow-up [odds ratio = 7.48, 95% CI: 3.09, 18.15]. More studies are needed to explore the natural history of the symptom. Despite some disagreement, the majority of the previous literature generally demonstrates an inverse association between both age and parity and dysmenorrhea [10, 13–15, 41].

This association was confirmed by the vast majority of studies included in this review, consistent across different types of study, although 3 studies failed to adjust for parity in their analysis on the association between age and dysmenorrhea [30, 32, 34]. Interestingly, Burnett et al. [26] found that the effect of age remained in the adjusted model including nulliparity, whereas the association between nulliparity and primary dysmenorrhea was no longer significant when controlled for age and smoking [$\beta = 0.93$; $P = 0.582$]. It is unclear though what the proportion of nulliparous women was in the study.

Furthermore, the study did find that the women most debilitated by pain were significantly more likely to be nulliparous. Nevertheless, the longitudinal study by Weissman et al. [37] provides stronger support for the inverse association between both age [odds ratio = 0.92, 95% CI: 0.86, 0.98] and livebirth [odds ratio = 0.20, 95% CI: 0.08, 0.53] and the severity of dysmenorrhea after controlling for each other; however, parity clearly had a much stronger effect in their analysis. In addition, the study also found that gravidity was less influential than livebirth, consistent with other studies showing no effect from pregnancies ending in miscarriage or abortion [15, 41].

Different mechanisms have been proposed for the relation between livebirth and dysmenorrhea. One is related to the pathogenesis of primary dysmenorrhea of the close association with elevated prostaglandin levels in the secretory endometrium that triggers pain [1, 42]. After a term delivery, the endometrium may release a lower level of prostaglandins, resulting in decreased pain [41]. Another hypothesis is that neuronal degeneration in the uterus following term pregnancy, due to disappearance of uterine adrenergic nerves and a decrease in uterine noradrenalin in the third trimester of pregnancy, may explain the disappearance or reduction of menstrual pain after childbirth [15].

A strong effect of family history of dysmenorrhea and risk of dysmenorrhea was shown in 2 studies, which is in line with some previous studies reporting a similar association, suggesting genetic susceptibility to dysmenorrhea among women with variant genotypes in a number of metabolic gene polymorphisms [20, 43]. However, other possible explanations are that the association could be related to conditioned behavior that is learned from mother or sisters for the possibility of societal reward or that control for pain exists [1]. Alternatively, it could be simply due to similar living patterns and lifestyles in the families [34]. Among the range of lifestyle and other demographic factors studied such as smoking, body mass index, and socioeconomic status, conflicting results were shown.

Previous studies on the association between smoking and dysmenorrhea are mixed. Although most cross-sectional studies show an increased risk among smokers [13, 14, 16], a negative effect was also seen [44]. Inconsistent results have also been observed for smoking and the incidence or the severity of dysmenorrhea in longitudinal studies [15, 18]. Sundell [15] found that the prevalence and severity of dysmenorrhea were increased in smokers and that the severity increased with the number of cigarettes smoked per day.

On the other hand, Harlow and Park [18] found that smoking was not associated with the probability of having pain or severe cramps but, among those with pain, smokers were more likely to have pain lasting longer than 2 days. Similarly, being overweight was found to be an important risk factor for the probability of experiencing pain and for increasing duration of pain in 1 longitudinal study [18], and severity of dysmenorrhea was not associated with either height or weight in another [15]. The systematic review also failed to detect a significant association between obesity and dysmenorrhea in the pooled analysis of 5 studies [40]. No association was shown among women's education, marital status, alcohol use, and the risk of dysmenorrhea in the current review, which is supported by the recent systematic review identified [40] and previous studies [14, 17, 18].

However, caution should apply when interpreting the systematic review results, as heterogeneity was present in all analyses with multiple studies, and the review is based largely on case-control studies that are subject to recall bias. A protective effect of OCPs or other forms of hormonal

contraceptive for dysmenorrhea is evident in the majority of previous studies [10, 13–15, 21], consistent across different study types.

This is largely confirmed by the current review, although 1 of the studies on a large sample of Indian women did not show any significant association between different methods of contraception, including OCPs, and moderate to severe dysmenorrhea [3].

The reason for this discrepancy may be due to the small number of women using OCPs [n = 43] in the study. There is evidence suggesting an association between early age at menarche and increased risk of dysmenorrhea [15, 18, 19], which is supported by the systematic review [40]. However, most of the studies reporting it in this review failed to show an association [26, 31, and 35] with the exception of the Indian study [3].

The reason for the discrepancy is not readily apparent, and the association may be confounded or mediated by other factors. Furthermore, although there is suggestion of some associations of other reproductive factors such as age at first birth, caesarean section, and heavy and irregular menses [14, 18, 41], this review is unable to reach any firm conclusion because of the limited number of studies reporting these effects. Among the psychological factors studied, a positive association between perceived stress, related to work or general life events, and the risk of dysmenorrhea was shown in most included studies.

The biological mechanism for association between work stress and dysmenorrhea is not well understood, although potentially through a cascade of neuroendocrine responses [36]. Stress inhibits the release of follicle-stimulating hormone and luteinizing hormone, leading to impaired follicular development. This can alter progesterone synthesis and release, which may influence the activity of prostaglandin.

Besides progesterone, stress-related hormones, including adrenaline and cortisol, also appear to influence prostaglandin synthesis and/or binding in the myometrium [36].

Furthermore, mental health may act as a mediator in the relationship between stress and dysmenorrhea, with high job stress increasing the risk of mental health morbidity, which in turn

is positively related to painful menses [28]. Of note is that these studies were generally conducted on groups of employed women, whereas another included cross sectional study of a random sample of Iranian women did not observe a significant association between stress level and the severity of pain in the adjusted analysis [34].

Conclusion

In conclusion, this review shows that dysmenorrhea is a significant symptom for a large proportion of women throughout the reproductive years. Severe dysmenorrhea limiting daily activities is much less common. Improvement of the symptom over time has been observed, although many women also experience unchanged or worse symptoms. From longitudinal or population data, this review has confirmed the following:

• Dysmenorrhea is inversely related to age, parity or number of livebirths, and oral contraception use;

• Dysmenorrhea is positively associated with stress related to both work and general life, as well as with family history of dysmenorrhea.

However, uncertainty still remains for a number of lifestyle factors, such as smoking, obesity and diet, psychological factors, and environmental factors. Furthermore, there is a lack of longitudinal data to study the natural history of dysmenorrhea and the effects of a range of modifiable risk factors over time. More research on these from population-based, prospective, longitudinal studies to generate robust evidence will help to support targeted preventive interventions.

Saveetha University, Chennai, India

Abstract

Dental caries (tooth decay) is one of the common dental problem in most countries, affecting 60-90% of school children and the majority of adults. Reports have brought out the evidence that green tea and ginger have a synergistic impact to limit the growth of bacteria such as E.coli owing to their anti-microbial effects. So the aim of the present study was to evaluate the anti-bacterial activity green tea and ginger alone and also their synergistic activity on Streptococcus mutans, the potent initiator and leading cause of dental caries worldwide. Antibacterial activity of green tea along with ginger was screened against Streptococcus mutans, using agar well diffusion technique. The results of this study showed that both green tea and ginger has got good antibacterial activity. But they didn't exhibit synergistic activity on the organism tested.

Materials and methods: Bacterial strain used was Streptococcus mutans. The organism was isolated. Isolation was done using selective media Mutans-Sanguis agar [Hi media M977], and maintained in nutrient agar slope at 4 in Department of Microbiology, Saveetha Dental College.

Results: Cinnamon and ginger have excellent antimicrobial activity on the growth of Mutans streptococci and lactobacilli, but their effects are more on lactobacilli than mutant streptococci. Cinnamon should be prescribed prior to ginger because it has more antibacterial activity on the growth on both bacteria types even in small concentration.

Conclusion: Green tea contains chemical ingredients such as polyphenols which possess antimicrobial, anti-inflammatory and anti-cariogenic effects. Oral rinsing with green tea reduces the quantity of cariogenic bacteria significantly and also decreases acidity of plaque and saliva as well. It can be used as a cost-effective caries preventive measure in developing countries.

Key Words: *Dental caries, agar well diffusion, synergistic effect, green tea, ginger.*

Introduction

Dental caries is the demineralization of the tooth surface caused by bacteria. [1, 2] The bacterial aspect of dental caries can be explained such that the bacteria produce acids that cause the irreversible solubilization of tooth structure. Streptococcus mutans is the main cause of dental decay while various lactobacilli are associated with progression of the lesion. Reports have brought out the evidence that green tea and ginger have a synergistic impact to limit the growth of bacteria such as E.coli owing to their anti-microbial effects. [3, 4]

The ability of this bacterium to produce (acid genic) and tolerate (acid uric) acids coupled with its property of synthesizing extracellular glucans allows its effective colonization in the oral cavity leading to the establishment of highly cariogenic dental biofilms [5]. Extracellular glucans which are synthesized from sucrose by glucosyltransferases (GTFs) play a critical role in the adhesive interactions of S. mutans and contributes to the structural integrity of dental plaque [6]. S. mutans expresses three different GTFs viz., GTF B, GTF C and GTF D. The insoluble and soluble glucan is mostly synthesized by GTF B and GTC C respectively. However, GTF C is known to synthesize a mixture of soluble and insoluble glucans [7]. These virulence properties thus provide a unique microenvironment for unobstructed survival of S. mutans in the oral cavity [8]. Therefore, approaches to inhibit various factors governing the virulence properties of S. mutans, could be an alternative to prevent dental caries.

There are numerous anti-plaque agents that are known to reduce dental biofilm formation amongst which fluoride is a well-known cariostatic agent [9]. However, its excessive use results in side effects like fluorosis and hence its use is limited [10]. Moreover, chlorhexidine which is considered as a standard anti-plaque agent have also been reported as genotoxic [11]. Therefore, despite of the presence of a variety of anti- plaque agents, the quest for an effective agent still continues. Therefore, the development of alternative therapeutic agents with anticariogenic properties and minimal side effects is a promising approach.

Zingiber officinale (or ginger), is one of the most extensively used herbs in the Indian system of traditional medicine. Many studies have revealed its numerous pharmacological activities, such as, antioxidant, antibacterial, anti-inflammatory, antinociceptive [12], antimutagenic [13] and

hepatoprotective [14]. Furthermore, there are several other studies showing the antibacterial effect of Z. officinale against a number of micro-organisms including S. mutans [15-17]. However, there are hardly any reports evaluating its anticariogenic potential. Hence, in view of the current need of alternative therapeutic approach, we initiated our study to provide an innovative and comprehensive insight of the effect of Z. officinale to inhibit various virulence traits of S. mutans.

Ginger has been known for medicinal purposes since antiquity. Ginger is from the botanical family Zingiberaceae. Its botanical name is Zinger officinale. The parts of the ginger plants that are of medicinal value are the rhizomes (underground stems). Ginger has long been an alternative therapeutic to prevent motion sickness i.e, nausea and vomiting. Its synergistic and individual impact with green tea is found to affect some bacterial populations.

Tea- the most preferred beverage of the century. The beverage tea has its roots in Southwest China, where green tea is not just a beverage but a medicinal drink too. The source of tea isCamellia sinensis[18].Thisaromatic beverage is commonly prepared by pouring hot or boiling water over the cured leaves of this plant. There are many different types of tea, such as white tea, green tea, yellow tea, black tea, oolong tea and pureh tea. The fact is that all these tea types have a common source, the Camellia sinensis. The processing method of the leaves after harvesting decides the type of tea produced.The different processing methods impart characteristic colour and flavour to the tea leaves. For our study, we chose three tea types, namely green tea, red tea and black tea respectively.

Green tea, an aqueous infusion of dried leaves of the plant Camellia sinesis, is the most popular beverage consumed worldwide [19]. It has received considered attention because of its scientifically proved beneficial effects on human health. The effect has been largely attributed to the poly phenol content namely epigallocatechin gallate which is known to induce apoptosis of tumor cells and has little or nil effect in normal cells [20, 21]. It is consumed throughout the ages in India, China, Japan and Thailand. Several epidemiological studies have proven that green tea also has some general health beneficial properties like anti- hypertensive, anti-bacterial, anti-viral and anti- fungal activity. Traditional Chinese medicine has recommended this plant for headache, body ache, and as an energy drink. It has cognitive function and positive impact on bone density, dental caries and periodontal health [22]. Green tea is usually available in the form

of beverage, mouth wash containing extract of green tea, and as a chewing gum. Green tea catching can be affected by various factors like type of green tea leaves, type of processing before drying, growing conditions and the geographic conditions. This present article reviews the effectiveness of green tea on oral health and periodontium.

Green tea is the most ancient and popular beverage consumed around the world it is made up of leaves of the plant camellia sinensis. It is loaded with polyphenols like flavonoids and catechins, which function as powerful antioxidants. These substances can reduce the formation of free radicals in the body, protecting cells and molecules from damage. These free radicals are known to play a role in aging and all sorts of diseases. One of the more powerful compounds in green tea is the antioxidant Epigallocatechin Gallate (EGCG), which has been studied to treat various diseases and may be one of the main reasons green tea has such powerful medicinal properties. Green tea also has small amounts of minerals that are important for health. Green tea can boost the metabolic rate in the short term, it makes sense that it could help you lose weight. Green tea contains many bioactive ingredients mainly polyphenols which play a key role in the prevention and treatment of many diseases the catechins in green tea may inhibit the growth of bacteria this can lower the risk of infections and lead to improvements in dental health, a lower risk of caries and reduced bad breath (halitosis) [23]

Green tea (Camellia assamica) is cultivated in many countries of the countries of the world, Japan being the largest producer in the world. Green tea has been chosen as a raw material for extracts used in different beverages, dietary supplements and cosmetic items.Green tea is derived from the dried leaves of the plant Camellia sinensis. Green tea is usually available in the form of beverage, mouth wash containing extract of green tea, and as a chewing gum. Green tea catching can be altered by different factors like type of green tea leaves, type of processing before drying, growing conditions and the geographic conditions. [24]Significant antibacterial activity has been reported for extracts of green tea. Green tea is observed to inhibit the growth of bacteria such as Streptococcus mutans and Lactobacillus acidophilus.

Materials and Methods

Test Microorganisms

Bacterial strain used was Streptococcus mutans. The organism was isolated. Isolation was done using selective media Mutans-Sanguis agar [Hi media M977], and maintained in nutrient agar slope at 4 in Department of Microbiology, Saveetha Dental College.

Methodology

The green tea and ginger were dissolved in distilled water in following concentrations 2.5mg/ml, 5mg/ml and 10mg/ml so that 100µl delivers 250µg/ml, 500µg/ml and 1000 µg/ml respectively.

Screening of antibacterial activity [Agar well diffusion technique]

Broth culture of the specified bacterial strain according to Mac Farmland's standard [24-26] 0.5 was prepared. On Muller Hinton agar [MHA-Hi media M1084] plate's lawn culture of the test organisms was made using sterile cotton swab and plates were dried for 15 minutes. Using a sterile well cutter wells measuring 4mm depth were made on the agar plates. 100 µl of different concentration of the extract were then filled in the wells. To determine the synergistic activity 50µl of green tea and 50µl of zinger extract from different concentrations were loaded on to the wells. 0.2% chlorhexidine was used as the positive control. The plates were incubated at 37°C overnight and the zone of inhibition of growth was measured in millimeters. All the tests were done in triplicate to minimize the test error.

Results and Discussion

The antibacterial activity of green tea and ginger at different concentrations was screened by agar well diffusion technique and zone of inhibition was measured in mm diameter. The results are given in Table 1. The green tea alone was more effective against Streptococcus mutans with a zone of inhibition of 22mm; ginger showed a zone of 19mm diameter and with both green tea and ginger the zone diameter was 20 mm.

The present study was to analyze the antibacterial activity of green tea and ginger alone and together on caries causing organisms. The results obtained from our study show that green tea and ginger have good antibacterial activity but do not have much of a synergistic impact against Streptococcus mutans.

There is convincing evidence that the different components of catechins have their action on different species of microorganisms responsible for caries production.

Taking two cups of green tea as a daily routine is good for the health as the results show that intake of green tea which contains catechins like epigallocatechin-3-gallate and polyphenols which show negative effect to the growth of bacteria and inhibit the growth of bacteria in the oral cavity which reduces the oral bacterial count and improves the oral health care so green tea plays a key role in prevention and treatment of many diseases.

Roopal V Patel demonstrated that combined extracts of ginger and honey showed maximum inhibitory concentration against S.mutans and S.aureus and were least effective against L.acidophillus in comparison with gentamycin, showing, there is a significant synergistic effect of antimicrobial activity from the combination of ginger and honey, against isolates from carious teeth [27].

Cinnamon and ginger have excellent antimicrobial activity on the growth of Mutans streptococci and lactobacilli, but their effects are more on lactobacilli than mutant streptococci [28]. Cinnamon should be prescribed prior to ginger because it has more antibacterial activity on the growth on both bacteria types even in small concentration (50mg/ml) [29].

Table 1:Anti-bacterial activity of Green Tea and Ginger

Organism	Conc. ml	E1 mm	E2 mm	E3 mm	Chlorhexidine mm
Streptococcus mutans	250µg/ml	14	08	10	24
	500µg/ml	17	12	14	27
	1000µg/ml	22	19	20	34

E1 – Green Tea, E2 – Ginger, E3 – Green Tea + Ginger

Conclusion

Green tea contains chemical ingredients such as polyphenols which possess antimicrobial, anti-inflammatory and anti-cariogenic effects. Oral rinsing with green tea reduces the quantity of cariogenic bacteria significantly and also decreases acidity of plaque and saliva as well. It can be used as a cost-effective caries preventive measure in developing countries. Ginger has been used as an herbal ingredient in dental products as well [30]. Together these two do not seem to significant synergistic effect.

Abstract

Introduction: The aim of this present study is to compare the effect of herbal and fluoride toothpaste on the bacteria causing dental caries.The effect of the herbal toothpaste and fluoride toothpaste are compared and hence an idea on how to prevent, control and treat the dental caries is formulated.Lactobacilli acidophilus have been associated with the presence and progression of dental caries.Production of organic acids by lactobacilli is considered to be important in causing decalcification of the dentinal matrix.

Material and Methods: One herbal toothpaste and fluoride based toothpaste are used for the study. The effect of these two toothpastes on bacteria causing dental caries like lactobacilli will be studied by agar will diffusion technique. The findings are compared between the groups.

Results: The results suggested that Herbal toothpaste had maximum antimicrobial activity at all concentrations when compared to Fluoride toothpaste.The higher antimicrobial activity of herbal toothpaste could be attributed to the presence of different components like Lavang and Elaichi.

Conclusion: The study showed dentifrice with combination of herbs had better effect in inhibiting cariogenic bacteria compared to the ones with fewer herbal ingredients.

Key Words:*Dental caries, fluoride, herbal, toothpaste, lactobacillus.*

Introduction

Toothpastes are recognised as the best source of fluoride, which most effectively protects both deciduous and permanent teeth from caries. The cleaning abilities of toothpaste provided by abrasives, the antibacterial qualities, which, in turn, are provided by a variety of substances with different abilities to inhibit the growth of germs in the oral cavity.The purpose of oral hygiene using toothpaste is to reduce oral bacterial flora [1].Toothpaste is by far the most commonly used mode of delivery of fluoride and the decline in the prevalence of dental caries in developed countries is mainly attributed to its increased use [2,3].The advantages of fluoridated products is well documented in the literature. It is the most spoken and debated topic all over the world with researchers having diverse views about its use and safety.The intensive promotion of fluoridated toothpastes by the oral health care industry is a major factor in their increased use.The other alternative toothpaste on the market for use by infants, do not contain fluoride in their composition, but have herbal products or enzymes to produce antiseptic or antimicrobial effects against cariogenic and opportunistic micro-organisms in the oral environment [4]. The components of natural toothpastes should be as safe as those of conventional toothpaste provides safe as those of conventional toothpastes, provide efficient,protection against carcinogenic microorganisms [5].This study is thus aimed at comparing the antimicrobial efficacy of triclosan containing fluoridated toothpaste and Herbal tooth paste.

WHO declares that deprived oral health and its related diseases may have dreadful effect on common health as well as eminence of life. Dental caries is a common and major public health oral disease which hampers the attainment and protection of oral health in different age groups. The prevalence pattern and severity of dental caries varies with age, sex, race, socio-demographic characteristics, economic status, geographical location, food practice and oral hygiene habits within the same country or region in various parts of the world.

During the last few decades, the incidence of microbial diseases has amplified drastically. Microorganisms are the super bug agent responsible for causing dental caries. Many facultatively and obligately anaerobic bacteria dominate the microbial community of dental caries. But, the most important etiological agent of dental caries is Streptococcus mutans. Tooth decay takes place when a vulnerable tooth surface is colonized with cariogenic microbes and dietary source of sucrose or re ned sugar. Fermentation of carbohydrate leads to production of lactic acid by the action of bacteria which melts the hydroxyapatite crystal

structure of the tooth which grounds caries [6].

The experience of pain, problem with eating, chewing, smiling and communication due to missing, discoloured or spoiled teeth have a foremost impact on people's everyday life. Low self-esteem, adverse pregnancy outcomes, increased risk of myocardial infarction, cardiovascular disease, respiratory, erectile, diabetes complications, cavernous sinus thrombosis and Ludwig angina are associated with dental caries which can be crucial to human beings. Moreover, oral diseases hamper activities at school, at occupation and at residence causing millions of school and employment hours to be vanished each year throughout the globe. As a consequence, the treatment need is enhanced nowadays.

Globally, there is a great interest in the use of antimicrobial agents for prevention and treatment of dental diseases. The emergence of antibiotic resistance has been identified due to inappropriate prescription and practice of antibiotic use. In the recent years, dentists and dental professionals has shifted their interest from narrow spectrum antibiotic prescriptions to broad-spectrum aminopenicillinsdue to enhancement of bacterial isolates resistant to the former antibiotics in prescription practices. Antibiotic resistance increases the morbidity associated with dental caries and contributes substantially to rising costs of care and the need for more expensive drugs [7].

Among the plethora of diseases manifesting in the oral cavity dental caries remains one of the most prevalent diseases of this site. Even with improved means to maintain oral hygiene dental caries occurrence is still on the rise. This is predominantly due to changing dietary habits and increased consumption of sugar [8]. Also factors like geographic, climate, cultural, ethnic and socioeconomic conditions also play an important role. The global distribution of dental caries has shown distinctive variations [9]. The scenario in India also shows similarities with other developing countries. Prevalence studies on dental caries in India have shown a results ranging from 31.5% to 89% [10].

Periodontal diseases and dental caries are the most prevalent oral infections affecting mankind worldwide. Endogenous oral bacterial species such as A.actinomycetemcomitans, Porphyromonas gingivalis, Streptococcus mutans, Streptococcus sorbicus, Bacteroides sp.,Prevotellamsp.,Fusobacterium sp., and their metabolites play major role in the initiation and progression of these infections. Effective prevention of these infections can be achieved

by mechanical removal of Dental plaque by proper tooth brushing and flossing. However, the majority of the population, particularly aged individuals, may not perform mechanical plaque removal sufficiently, and thus antimicrobial mouth rinses such as triclosan and chlorhexidine may be used to limit these two plaque-related oral infections. These chemical agents used in the form of either dentrifrices or mouth rinses may have undesirable side effects such as tooth staining, taste alteration and development of hypersensitivity reactions. Although antibiotics are used routinely to prevent systemic infections originating from the oral cavity, they are not recommended for regular prevention of dental plaque formation because of the risk.

It is well established that most infectious oral disease such as dental caries and periodontal disease are linked to the microbial flora of the oral cavity. Dental caries is caused by acidogenic species of bacteria, mainly S.mutans, Lactobacillus and Actinomyces. These oral bacterial species metabolise sucrose to lactic and other organic acids in dental plaque produced on the surface of the tooth and dissolve calcium phosphate in the enamel, consequently giving rise to dental caries. Periodontal disease is mostly associated with anaerobic gram-negative rods such as A.actinomycetemcomitans, P.gingivalis, Tannerellaforsythus, Bacteroides, prevotella and Fusobacterium species. These periodontopathogens are frequently isolated from periodontal pockets of patients with periodontitis.

Materials and Methods

Toothpastes

Three toothpastes namely fluoride toothpaste A , a Herbal Toothpaste B and a herbal Toothpaste C were selected for this study. The products were collected from local market, Chennai.

Tests for Microorganisms

Bacterial strain was lactobacilli which is a fermentativebacteria and considered as a probiotic. Lactobacillus acidophilus was obtained from Microbiology Lab, Saveetha Dental College,Chennai.

Methodology

The antimicrobial activity of different concentrations of the dentifrices was determined by modified agar well diffusion method. Lawn culture of the test organisms were made on the Muller Hinton agar [MHA-Hi media M1084] plates using sterile cotton swab and the plates were dried for 15 minutes. Dentifrice dilutions at different concentrations were introduced into each of the three wells. The uninoculated plates were maintained as a control. The plates were incubated at 37o C for 24 hours for isolation of bacteria.The antimicrobial activity was evaluated by measuring the diameter of zones of inhibition (mm).

Result

The antibacterial activity of the three toothpastes at different concentrations was screened by modified well diffusion technique and the zone of inhibition was measured in mm diameter. The herbal toothpaste B was more effective against lactobacilli with a zone of inhibition of 29mm diameter, fluoride toothpaste A showed a zone of 25mm diameter and with the herbal toothpaste C the zone diameter was 23mm.Thus, One herbal tooth paste with multiple herbal ingredients had greater zone of inhibition compared to the fluoride containing tooth paste and other herbal toothpaste. The results are given in Table1.

Table 1: Zone of inhibition of three toothpastes(mm)

Organism	Fluoride toothpaste A	Herbal toothpaste B	Herbal toothpaste C	Control chlorhexidine
Lactobacillus acidophilus	25mm	29mm	23mm	29mm

Discussion

Good oral hygiene is necessary for the healthy teeth, gum and fresh breath. Fluoride and plant extracts incorporated in toothpastes help to protect teeth by binding with enamel to make it stronger [11]. Most of the people use toothpaste without knowing their potential efficacy, bacteria form an important group of micro-organisms found in both healthy and diseased mouths. It is of importance to know the role of plants play in

oral hygiene as a number of them have medicinal properties.Natural toothpastes are those without triclosan or fluoride (herbal toothpaste). They usually contain natural ingredients such as special mineral salts like Sodium fluoride and sodium chloride, and plant extracts like lemon, eucalyptus, rosemary, chamomile, sage and myrrh. There are toothpastes and other remedies that help kill and prevent bacteria in people's mouths[12]. Dental caries is a multifactorial disease in which, streptococci mutans and lactobacilli in dental plaque, play an important role. Lactobacillus species and other non-mutans acidogenic and acid-tolerant bacteria are also known as significant etiologic agents [13]. Furthermore, few research efforts have been directed toward addressing the potency or quality of herbal ingredients used in these dental products. It is generally agreed that, with the exclusion of fluoride from most natural herbal dentifrices, these dentifrices usually forfeit caries-preventive benefits [14]. While many herbal dentifrices claim to have antimicrobial properties and have caries preventive action, very little research has been conducted to investigate these claims.Results indicate that both herbal toothpaste and fluoride containing toothpaste were effective against both the cariogenic bacteria. The zone of inhibition when compared, the herbal dentifrices were comparatively better than the fluoride containing tooth pastes. Chemicals, mainly triclosan and chlorhexidine, have been added in mouth rinses and dentifrices to prevent plaque and gingivitis. But some of these substances show undesirable side effects such as tooth staining and altered taste. This had led to paying increased attention on using natural ingredients in herbal dentifrices. Herbal ingredients have several benefits; chamomile has anti-inflammatory effect, echinacea has immune stimulatory property, sage and rhatany have anti-hemorrhagic properties, myrrh is a natural antiseptic, and peppermint oil has analgesic, antiseptic, and anti-inflammatory properties. There are limited studies available regarding the efficacy of herbal dentifrices; hence, the present study was undertaken to assess their plaque and gingival preventive action.

Our study mainly concentrates in comparing efficacy of herbal dentifrices with conventional ones in inhibiting cariogenic bacteria, suggesting that efficacy of herbal dentifrices is similar and some have superior antibacterial efficacy [15]. Herbal toothpaste is available in most rural areas of the poor countries. It does not need expertise or any extra resources to manufacture it. Thus it appears to be a potent antimicrobial agent that could be considered as a medicinal plant. Thus provides evidence to the claim of anti-cariogenecity of herbal dentifrices[16]. The study also

showed dentifrice with combination of herbs had better effect in inhibiting cariogenic bacteria compared to the ones with fewer herbal ingredients[17].

Dental plaque deposit on teeth is a concern for both cosmetic and its pathogenic nature. Presence of plaque may be the culprit for dental caries, gingivitis, periodontal problems, and halitosis. Many mechanical aids are used worldwide to remove or control plaque, including tooth brushes, dental floss, mouth rinses, and dentifrices.Mechanical plaque removal is one of the most accepted methods of controlling plaque and gingivitis. But it is expected that less than one-third of the population can effectively perform mechanical plaque removal. Several chemical preventive agents have beneficial effects in the control of plaque and to reduce or prevent oral disease. Hence, various chemical formulations were tried in dentifrices[18]. Chemicals, mainly triclosan and chlorhexidine, have been added in mouth rinses and dentifrices to prevent plaque and gingivitis. But some of these substances show undesirable side effects such as tooth staining and altered taste[14]. This had led to paying increased attention on using natural ingredients in herbal dentifrices. Herbal ingredients have several benefits; chamomile has anti-inflammatory effect, echinacea has immune stimulatory property, sage and rhatany have anti-hemorrhagic properties, myrrh is a natural antiseptic, and peppermint oil has analgesic, antiseptic, and anti-inflammatory properties[19].This study has proved that herbal dentifrices do not cause any adverse effects on the oral cavity and are effective in reduction of plaque and gingivitis, as that of fluoridated non-herbal dentifrice. Several studies have proven the medicinal values of herbal products. Hence, medicated herbal toothpastes can be safely used to control plaque and gingivitis. Further long-term studies are required to prove their effectiveness[20].

During recent years, many researchers throughout the world have studied Miswak as a helpful plant in oral hygiene. Clinical trials have shown that regular use of chewing stick of Salvadora Persica reduces plaque. It has been reported that incidence of caries among users of chewing sticks is low despite the intake of a carbohydrate rich diet and a lack of modern dental prophylactic measures[21].The Arabian researchers concluded from a comprehensive survey of several thousands of Saudi school children that the low incidence of gingival inflammation was attributable to the practice of using Miswak for teeth cleaning (Gazi et al 1992).

In vitro studies indicate that, of a variety of common oral bacteria, members of the genus streptococcus (including the mutans streptococci) are especially sensitive to the

antimicrobial activities of S. Persica (Al-lafi&Ababneh 1995).

In a study the efficacy of Miswak in the prevention of dental caries has been investigated and compared with the efficacy of ordinary toothbrush and toothpaste[18]. The data collected at the end of the study showed that the risk of dental caries for each tooth in the control group was 9.35 times more than the case group (Aldini&Ardakani 2007).

It has been told rinsing with Miswak extract stimulated parotid gland secretion and raised the plaque PH, suggesting a potential role in caries prevention (Sofrata et al 2007).

It has been observed that miswak was as effective as a toothbrush for reducing plaque on buccal surfaces of teeth both experimentally and clinically (Mohammed et al 2006).

Another study compared the oral health efficacy of persica mouthwash with that of a placebo. The results showed that use of persica mouthwash improves gingival health and lower carriage rate of cariogenic bacteria when compared with the pretreatment values (Khalessi et al 2004).

Scientific evaluation of use of miswak revealed that it is at least as effective as toothbrushing for reducing plaque and gingivitis and that the antimicrobial effect of S. persica is beneficial for prevention/treatment of periodontal diseases (Al- Otaibi 2004).

A clinical study was conducted using patients` saliva and measuring the effect of miswak (chewing stick), miswak extract, toothbrush, and normal saline on mutans and lactobacilli[19]. The results showed that there was a marked reduction in Strep. Mutans among all groups.When the groups were compared, the reduction in Strep. Mutans was significantly greater using miswak in comparison to toothbrushing and there was no significant differences for lactobacilli reduction[21]. The investigators concluded that miswak has an immediate antimicrobial effect. Strep. Mutans were more susceptible to miswak antimicrobial activity than lactobacilli (Almas & Al-Zeid 2004).

Conclusion

Lactobacilli acidophilus were quantitatively assessed by the presence or absence of inhibition zone and their zones diameter. Among this, herbal toothpastes showed the highest resistance capacity. The herbal tooth pastes have similar and slightly better antibacterial activity compared to the conventional tooth pastes. The herbal tooth pastes which have combination of herbs have better antimicrobial activity compared to those with single ingredient against certain organisms. Thus turning to nature can be as good as the latest

advances. These traditional methods have numerous other claims also which are of great benefit for health. Exploring and harvesting these herbal products and blending the same with the advances may make oral and health care better. Thus the present article also provides insight to the dentists that the herbal toothpastes are equally effective as the conventional toothpastes and can be advised to those who prefer natural products.

Abstract

Background: Prevalence of oral cancer is high in India, other Asian countries, Brazil and France. Micro nutrients like copper and zinc are increasingly recognized for their role during the onset and progression of pre malignant and malignant orallesions. The aim of this study is to determine serum levels of copper and zinc among oral cancer patients**.** The objective is to estimate and compare the serum levels of copper and zinc in healthy and cancer patients and to derive Cu/Zn ratio, to establish a possible relationship between micro nutrients and oral cancer.

Materials and Methods:25 patients clinically diagnosed with oral cancer (study group)and 25 healthy individuals (control group)in the age group of 30-50 years were included in the study. Blood samples were collected and serum copper and zinc valuesfor both cancer and control group wereestimated using ERBA CHEM 5 semi auto analyzer. Mean and standard deviation of serum copper and zinc values for both groups weredetermined and compared. .

Results: Significantly higher values ($p < 0.04$) were noted for serum copper level (mean value249.39± 58.3µg/dl) for study group compared to control group (123.95 ± 16.2µg/dl).However there was no significant difference in serum zinc values between the groups.

Cu /Zn ratio of 1.43 and 2.86 for control and study group respectively was derived from the estimated value

Conclusion: Mean serum copper value in study group was significantly higher than in the control groupand may be considered as a biological marker for oral cancers.

Keywords*: Serum micronutrients, serum zinc, serum copper, premalignant, malignant oral lesion*

Introduction

Oral cancer is one of the most prevalent and 6th most common type of cancer in the world [1]. Prevalence of oral cancer is higher in, India, Asia Brazil and France compared to other countries globally.Incidence and distribution varies by age, ethnic group, culture and lifestyle associated factors [2]. Alcohol, viruses, genetic mechanisms, Candida and chronic irritation have modifying effects on the etiology of oral cancer .Tobacco can cause genetic damage and can lead to development of oral cancer. Smoking and alcoholconsumption are major risk factors [3]. It mostly affects the tongue,buccalmucosa, gingiva, lips, and palate [4].It was also found that higher intake of fruits and vegetables had lower risk of oral cancer but an unbalanced diet has been related to an elevated risk [5]. Clinical and histopathologicalexamination of oral lesions plays a major role in the diagnosis of oral cancer. In addition, it has been reported that levels of trace elements or micro nutrients such as copper, zinc, iron and selenium are altered in serum, plasma and tissues of pre malignant oral lesions [2] [6].

Copper, zinc, iron are chemical elements required in minute quantities for vital biochemical reactions such as free radical formation and cellular homeostasis[2].The enzymes of trace elements are an important part of certain biological and chemical reactions [7].Zinc is also an important constituent ofbiologicalbio membranes and contributes to membrane stability.It modulates activities of ribonucleic acid and deoxyribonucleic acid polymerase enzymes [8, 9].Theimportance of zinc for a healthy immune system, cell division, skin,hair, and muscle growth needs no mention.

Copper is involved in the release of energy during cell formation of red blood cells, collagen production, and iron absorption.

However, it was found that there is a potential link between trace elements and carcinogenesis. The ratio of copper to zinc is also believed to be a reliable biomarker in the development and progression towards malignancy [10].Copper and zinc are often recognized for their possible role in the prevention and modulation of diseases but recent studies have proved increased level of copper and decreased level of zinc in cancer [11].

The present study was undertaken to evaluate and compare the levels of copper and zinc in the blood serum ofnormaland patients with oral cancer.

Materials and Methods

The sample for thepresent studyconsistedof 50 individuals.25 healthy individuals from the outpatient clinic accepted to participate in the study as controls. 25 patients diagnosed with oralcancerwereincludedastheobservationalstudy group from the outpatient department, Oral Cancer Institute of Saveetha dental college. The study wasapproved by the Institutional Ethical Committee and informed consent was obtained from the patients prior to the blood sample collection. The participants were chosen based on thefollowing inclusion andexclusion criteria. Inclusion criteria included patients diagnosed with carcinoma, in the age group 30 – 50 years, and for control group, healthy individuals with no history of systemic disorders were chosen.Exclusioncriteria included immunocompromised adults, patients diagnosed with endocrine disorder, coronary artery disease andinfectious diseases like tuberculosis orsyphilis.Methodology included collection of 5ml of blood sample under absolute asepsis and transferred to acid washed test tubes .The blood collected was centrifuged at 2500rpm for 15 minutes and preserved in a frozen state untilanalysis. The samples were then analyzed using ERBA CHEM 5 semi auto analyzer. Serum levels of zinc and copper were assessed with the help of reagentsprovided.

The data obtained, was statistically analyzed using the SPSS software. Range of values of all the samples for serum copper and zinc were evaluated and grouped(Tables, II). Mean and standard deviation for serum copper and zincof both the groups were determined and compared for statistical significance $p<0.05$ (Table III). Cu/Zn ratio was then derived from the above estimated value.

Results

Analysis of the data revealedthat serum zinc values ranged from 60µg/dl to 119µg/dl in both the groups. (Table I).However a maximum of 8 samples was in the range of 100- 109µg/dl in controls, and a maximum of 7 samples were in the range of 90 - 100µg/dl in the study group. The mean value for serum zinc in control group was 86.64±17.4 µg/dl, whiletheserumzinclevel in the study group was found to be 85.17±14.98µ/dl (Table

III).There was no statistically significant difference in the mean serum zinc values betweenstudy and control groups.

Zinc serum level observed in the study	No. of samples in cancer study group (n=25)	No. of samples in control group (n=25)
60-69µg/dl	3	3
70-79µg/dl	2	4
80-89µg/dl	4	5
90-100µg/dl	7	5
100-109µg/dl	3	8
110-119µg/dl	6	0

On the contrary,the serum copper level ranged from 180-340ug/dl in study group whilein the control group it varied from 110-160ug/dl. (Table II). A maximum of 8 samples were in the range of120-129µg/dl in the control and a maximum of 8 were in the range of 300-339µg/dl in the study group. The mean serum copper values werefound to be higher instudygroup 249.39±58.3µg/dl, compared to that of healthy control group123.95±16.2µg/dl.(TableIII). Mean serum zinc levels showed no changes.

Cu /Zn ratio was1.43 and 2.86 for control and study group respectively.

Discussion

Trace elementsCopper (Cu), zinc (Zn), selenium (Se) and molybdenum (Mo) are required in small concentration and have important role in many biochemical reactions. They are essential for proper functioning of life supporting processes and are an essential component of biologically active constituents [13, 14]. Copper is found in plasma (90-95%) as part of oxidative enzyme cerulo plasmin [15]. It is also a part of various enzymes like tyrosinase, cytochrome oxidase etc., and participates in oxidative process in cell metabolism. Zinc another micro nutrient is essential for gene transcription and cell multiplication and critical for activation of

RNA and DNA polymerase activity. Decreased zinc levels are associated with increased oxidative stress at cellular level [16].

The normal serum copper and zinc levels are 0.6 - 1.6µg/ml and 0.6 -1.5µg/ml respectively where atomic absorptionspectrometry has been used for analysis [17]. Others [10] have reported 114.20±38.69mg/dl, 64.57±31.54 mg/dl as copper and zinc values respectively in their control sample by means of calorimetric method. The values of these trace elements estimated in the present study were performed with ERBA CHEM 5 semi auto analyzer.

Concentrations of copper when exceeds the optimal level turn's toxic. It breaks down the DNA strands or modifies the bases and deoxyribose[12].Sliwinski et al observed that zinc did not induce DNA damage in normal cells but exerted a protective effect against DNA damaging agents but increased cytotoxic effect on cancer cells[11]. A number of studies have estimated copper and zinc levels in serum, blood and saliva in various carcinomas especially oral squamous carcinoma and have established a positive correlation with the incidence of malignancy. Significant alteration in serum levels of the trace elements have been reported in head and neck cancer, lung and breast cancer [2, 18]. The increased levels of copper andzinc in cancer reported earlier have been 209.85± 160.28mg/dl, 113.51± 52.30mg/dl respectively [10]. In the present study, copper showed a significant increase [249.39±58.3µg/dl] in oral cancer group compared to controlgroup [123.95± 16.23µg/dl].Similar findings have also been reported by Khanna et al,Amitkumar et al, Yunus et al, AyinampudiBK,Jayadeep A et al and Shetty SR et al. [2, 6, 10, 17, 19, 20,21and 22]. They observed increased copper levels in sera of patients in oral pre malignant and malignant patients.

The increased level of serum copper in OSMF patient was attributed by Khanna et al to high copper content in areca nut, the major physiological factor in the pathogenesis of OSMF [17] it initiates fibrin genesis and inhibit collagen degradation. It has also been explained that increase in serum copper levels in cancer patients is a consequence of increased production of copper containing cerulo plasmin an oxidative enzyme which is precipitated by an inflammatory response to cancer or decrease in catabolism by serum cerulo plasmin [16]. Jayadeep et al also suggested that rise in copper levels might be due to increased turnover of cerulo plasmin, a copper carrying globulin with oxidative activity [19].

Review of literature indicates low serum zinc level in several forms of cancer like cancer of breast, gallbladder, lung, colon and oral cancer [23, 24]. Serum zinc level in a present study did not reveal a similar finding. The serum zinc level among cancer patient in the present study was marginally lower or similar to

control group. Contrary to this finding statistically significant decrease in mean serum zinc levels have been reported by various other studies [18, 20, and 25].

Amit kumar et al [6] suggestedthat zinc deficiency impair protective mechanism designed to protect against DNA damage, enhance susceptibility to DNA damaging agents and ultimately increased risk of cancer

Increased copper zincratioseenin oral sub mucousfibrosis (OSMF) and oral squamous cell carcinoma (OSCC) was also noticed in patients with pancreatic cancer, breast cancer, lymphoma etc. Yunus et al concluded that alterations in serum copper, zinc, copper zinc ratio can be used as potential biomarkers in early detection of oral pre cancerous lesion and their malignant transformation to frank cancer at early stages [2].In the present study the ratio was 1.43 in control,and increased to 2.86 in the study group, probably due to increased copper values. Other reports have shown that Cu/Zn ratio was 0.97 in health and 1.10 in cancer patients, but the difference was not statistically significant [17,26].

This study confirms the earlier reports on the possible relation between serum copper level and oral cancer and can be considered as a biochemical marker for oral cancer. Further evaluation onpatients with oral premalignant lesions need to be performed which will be a major contribution to cancer screening programs .

Conclusion

Trace element copper level in oral cancer patients did show asignificantincrease compared to control group. Serum zinc level however did not show any difference between study and control groups.Alterations in serum copper level are suggestive of its important role in oral carcinogenesis, contributing to changes in Cu/Zn ratio.

Estimation of Fluoride Concentration Level in Coimbatore (TN)

Vidhya.T.K[1],Pradeep Kumar[2], Saravana Pandian[3],

Graduate Student[1],Reader[2], Department of Public Health Dentistry, Senior Lecturer[3], Department of Orthodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: The aim and objective of this study is to evaluate the fluoride concentration of drinking water that is available in Coimbatore.

Material and Method: The fluoride concentration of drinking water collected from Pollachi is analysed. The F ion selective electrode method was used to measure the F concentration in the samples. The measurements were obtained for every sample to ensure reproducibility and appropriate statistical analyses were employed.

Results: The fluoride content is compared with EPA and WHO guidelines of drinking water.

Conclusion: Fluoride in water is usually of geologic origin. Waters with high levels of halide content square measure principally found at the foot of high mountains and in areas wherever the ocean has created geologic deposits. Intake of excess halide, most ordinarily in drinking-water, will cause pathology that affects the teeth. The management of drinking-water quality is thus crucial in preventing pathology.

Key Words: *Fluoride, water, estimation, concentration.*

Introduction

Water may be a chemical substance with the statement binary compound. A water molecule contains one element and 2 atomic number 1 atoms connected by valency bonds. Water may be a liquid at close conditions, however it typically co-exists on Earth with its solid state, ice, and vaporised state (water vapor or steam). Water conjointly exists in a very liquid state close to deliquescent surfaces . below word wont to name chemical compounds, alter oxide is that the scientific name for water, tho' it's nearly ne'er used .Water covers seventy.9% of the layer, and is important for all legendary kinds of life on Earth, 96.5% of the planet's water is found in oceans, 1.7% in groundwater, 1.7% in glaciers and also the ice caps of Antarctica and Greenland, a-little fraction in alternative giant water bodies, and 0.001% within the air as vapor, clouds (formed of solid and liquid water particles suspended in air), and precipitation. Only 2.5% of the Earth's water is fresh, and 98.8% of that water is in ice and groundwater. Fluoride is naturally occurring substance which is present in water [1]. Fluoride when present in optimal quantities is known to prevent caries by various mechanisms but more predominantly by deposition of calcium fluoride crystals which is more resistant to demineralisation [2].Community water fluoridation began as early as 1945 and is considered as an effective way of preventing caries in children as well as adults [3]. The World Health Organisation has identified dental caries as a worldwide epidemic and also recommended to add fluoride to drinking water in naturally occurring water which has less than optimal fluoride levels. The optimal fluoride level in drinking water is 0.7 to 1.2 ppm [4]. Fluorine is the most abundant element in nature, and about 96% of fluoride in the human body is found in bones and teeth. Fluorine is essential for the normal mineralisation of bones and formation of dental enamel Fluorine is often called as two-edged sword. Fluoride is the major component in water which prevents dental caries. If the level of fluoride in bottled water is too low, optimal caries prevention may not be achieved whilst if levels are too high, developing teeth may be at risk of enamel fluorosis. Logaswamy et al. assessed the standard of groundwater in Kavundampalayam region in Coimbatore district and finished that groundwater quality varied drastically. Sundar et al. studied the groundwater quality on Noyyal watercourse in Coimbatore district and finished that the studied parameters were on top of the standards. a shot has been created to work out the suitableness of groundwater in Coimbatore district for various functions. The groundwater quality of the Singanallur sub-basin are analysed by Priya et al. to envision its suitableness for drinking, irrigation further as

domestic usage. it absolutely was finished that the Singanallur tank water was of dangerous quality thanks to the discharge of domestic sewerage. The seasonal differences within the groundwater quality of Coimbatore town throughout the year 2011 are analysed throughout pre-monsoon and post-monsoon periods victimization Geographic data system (GIS) by Jebastina et al .supported the water quality index, the samples were categorised as glorious, good,poor, terribly poor and unsuitable. Variable applied math analysis, cluster analysis and Principal part analysis were performed by Jebastina et al. on water quality information of twenty seven samples collected among Coimbatore district. The attainable factors that cause contamination are identified. Water quality index has been calculated by Priya et al. for the Singanallur sub-basin and also the entire sub-basin was zoned to check the suitableness of water for drinking functions victimization the thus ware ArcGIS and also the results showed that the groundwater quality was international organisation t for drinking in a number of the areas marking a water quality index bigger than one hundred.

Knowledge of the fluoride content of the drinking water is essential to all oral care professionals to plan of preventive dental programs and prescribes of fluoride supplements. Evidence of fluoride content in drinking water around Coimbatore district, India is largely anecdotal. Hence this study was designed to estimate the fluoride concentration in drinking water in Coimbatore district.

Material and Method

Coimbatore also known as Kovai, is a major city in the Indian state of Tamil Nadu. Located on the banks of the Noyyal River surrounded by the Western Ghats, it is the second largest city in the state after Chennai and 16th largest urban agglomeration in India. It is the largest city in the Kongunadu region. It is administered by the Coimbatore Municipal Corporation and is the administrative capital of Coimbatore district. It is one of the fastest growing tier-II cities in India and a major hub for textiles, industries, commerce, education, information technology, healthcare and manufacturing in Tamil Nadu. It is often referred to as the "Manchester of South India" due to its cotton production and textile industries. Coimbatore is also referred to as the "Pump City" and it supplies nearly half of India's requirements of motors and pumps. The city is one of the largest exporters of jewellery, wet grinders, poultry and auto components with "Coimbatore Wet Grinder" and "Kovai Cora Cotton" recognised as Geographical Indications by the Government of India.

Coimbatore has an area of city 246.75 km2 (95.27 sq mi) and Metro 642.12 km2 (247.92 sq mi). Coimbatore has a population of 1,601,438. As per the 2011 census based on pre-expansion city limits, Coimbatore had a population of 1,050,721 with a sex ratio of 997 females for every 1,000 males, much above the national average of 929. It is the second largest city in the state after capital Chennai[47] and the sixteenth largest urban agglomeration in India. A total of 102,069 were under the age of six, comprising 52,275 males and 49,794 females.The average literacy of the city was 82.43%, compared to the national average of 72.99%.

Collection of Water Sample

About 500ml of water was collected in a clean dry polythene container and labeled with information like date of collection, source and place. Fluoride levels were analyzed by ion exchange method by the chief water Analyst, state level water testing laboratory, Tamilnadu Water Supply and Drainage Board (TWAD), Government of Tamilnadu, Chennai (ISO 9001-2000- Certified).

Results

Source

Open well

Experimental Section

The fluoride concentration of drinking water collected from Coimbatore around 5 places Singanallore, Kaliyapuram, Karupapalayam,Puliyakulam, and Agilandapuram. Thereafter it was subjected to analysis for the estimation of fluoride at the Tamil Nadu Water supply and Drainage Board using the SPADNS colorimetric method.

Table 1: Fluoride content of drinking water in Coimbatore, TN.

S.NO	PLACE	FLUORIDE CONTENT IN WATER
1	Singanallore	0.130
2	Kaliyapuram	0.882
3	Karupapalayam	0.116

4	Puliyakulam	0.043
5	Agilandapuram	1.424

Table 1 shows the fluoride ion concentration in drinking water in Coimbatore. It was found that fluoride content ranging from 0.04 to 1.424.

Conversely, some drinking water contains insignificant amounts of fluoride which may deprive the child of the optimal daily fluoride requirement [5]. However, in view of increasing awareness of toxic effects of elevated F intake, particularly in children, it is important that the F level of drinking water be monitored closely to prevent adverse reactions to F from that source.

Discussion

In the present study, fluoride contains in all samples ranged from 0.04-1.42 mg/L, which is less than optimum range of 1.5 mg/L, as recommended by WHO. Hence, fluoride contents in all the samples exhibit their suitability for drinking. In a study to assess the groundwater fluoride concentration in Kanchipuram by Pradeep Kumar during 2014 it was found that the fluoride concentration ranged between 0.05-1.04 mg/l. (6). Similar studies done by Pradeep Kumar in ChennekothapalliMandal, Anatapur District, Andra Pradesh the fluoride concentration was 1.46 and 1.68mg/dl (7) and in Ennore, Chennai it ranged from 1.83 to 2.01 ppm (8,9). In general, fluoride is value-added to water as a removal agent to get rid of microorganism and alternative doable contaminants (Sharma and Soneja,2003).In numerous countries, particularly in developing countries, fluoridization is commonly embarked upon so as to enhance the facility. Water fluoridization may be a relatively cheaper and easier possibility for many components in Central Asia, whose would like for water removal is imperative.(10) On the opposite hand, developed countries have higher water removal choices therefore sanctionative them to disenlist the fluoridization of water in their water purification schemes. In Central Asia, fluoridization of water is living despite the substantive proof of high levels of water fluoridization in several regions of Asian country, Asian nation and alternative Central Asia countries.(11,12) However, in recent years, numerous health problems relative to the persistent introduction of halide within the water are raised.Based on the assessment conducted by British earth science Survey(2012), fluoride build-up has became considerably apparent within the ground waters of Central Asia and African countries

that are hardest hit embody China, India, Sri Lanka, Pakistan, and alternative African and South yankee territories (British earth science Survey, 2012).Fluorosis arose in Asian nation and have become major problems for its numerous territories, together with Andra Pradesh and province. pathology additionally emerged as a significant issue in Democratic Socialist Republic of Sri Lanka and Bangla Desh (Fawell et.al.,2006).In Asian country, fluorisis is additionally a significant health issue, significantly in metropolis, Kusur and Sargogha districts (Tariq et.al.,2012).In recent years, recommendations on the elimination or a minimum of the reduction of halide within the water are steered as a healthier possibility for the removal of water. To some extent, reduction in halide usage has been implemented; but, undeniably, the health effects of halide in water ar still persistent.(13)

The fluoride content within the well water of the Coimbatore District varied from 0.2 to 1.2 mg/L in 2007 with minimum worth in VadavalliPoosarpatti and most in P.N palayam. In 2008 the concentration of halide varies from 0.2 to 2.3 mg/L with minimum worth in Gopalapuram and most in Kavundampalayam. throughout 2009 the variation in fluoride from 0.1 to 2.7 mg/L with minimum worth in Dayanur, Mandripalayam, Natchipalayam, Senjeripudur and most worth in Andipalayam and in 2010 the fluoride concentration varies from zero.1 to 2.5 with minimum worth in Bogampatti, Kolarpatti, Marudur, Samathur, Valparai and most worth in Andipalayam and P.N palayam.It is possible that this deficiency in halide or its low concentration may need affected the dental health of the shoppers. From the Indian Standards (ISI, 1991), 1.0 mg/L is that the fascinating limit of halide in potable and low halide level could cause decay and high fluoride level ends up in pathology. The sources of halide in well water could also be because of weathering of igneous and matter rocks, phosphate fertilizers, that area unit extensively used, typically contain halides as impurity and these could increase levels of fluoride in soil. the buildup of fluoride in soil eventually ends up in its leach because of percolating water, therefore increase halide concentration in well water (Alexander, 2008).(14, 15)

Fluoride may be a chemical that happens naturally at intervals many sorts of rock. the common concentration of inorganic halide from natural sources in Asian nation normal drinkable is mostly lower than 0.050 milligrams per metric capacity unit (mg/L), however concentrations will get beyond one mg/L. the utmost Acceptable Concentration of halide in drinkable in Asian nation is one mg/L. fluoridization is that the addition of halide compounds into drinkable, to regulate concentrations to levels between 0.8 and 1.0 mg/L for the helpful

result of dental caries hindrance.(16) The general public also are exposed to halide in dentifrice or alternative dental merchandise. Most of the halide found in groundwater is of course occurring from the breakdown of rocks and soils or weathering and deposition of part volcanic particles. halide may come back from in runoff and infiltration of chemical fertilizers in agricultural areas, septic and waste matter treatment system discharges in communities with fluoridated water provides and liquid waste from industrial sources.(17)

At low concentrations fluoride will scale back the danger of dental cavities. Exposure to somewhat higher amounts of fluoride will cause dental pathology. In its mildest type this leads to discolouration of teeth, whereas severe dental pathology includes corrosion and alteration of enamel. Even higher intakes of halide confiscated an extended amount of your time may result in changes to bone, a condition referred to as skeletal pathology. this will cause joint pain, restriction of quality, and probably increase the danger of some bone fractures.The maximum level of halide that the frame could tolerate is 1mg/l. keeping in sight the assorted sources through that halide finds entry into the body, level of + 1.0 mg/l halide in water is taken into account because the optimum level to forestall each decay and numerous types of pathology.(18) The utmost limit prescribed by BIS (Bureau of Indian Standards) for halide in drinkable is additionally 1mg/l. The concentration of halide was determined as 0.2 mg/l, and also the most concentration values were determined as 1.4 mg/l in a recent study conducted in dharmapuri district. Fluoride happens in sellaite, fluorite, cryolite, apatite, apatite, fluormica, biotite, mineral alternative|and several other rocks. Weathering of those rocks and prolonged residence time results in high halide groundwater.(19) Low atomic number 20, high atomic number 11 and high hydrogen carbonate area unit typical of high halide groundwater. the opposite sources for halide area unit infiltration of agricultural run off containing chemical fertilisers, improper disposal of liquid waste from industries, alumina smelting, cement production and ceramic and brick firing. Some quantity of halide is essential for the physical structure for healthy teeth and bones.The popular technologies for the removal of halide from water embody natural action followed by precipitation, membrane processes, action and surface assimilation. In natural action, trace amounts of halide ions tend to stay in answer because of solubility restriction.Clinical dental pathology is characterised by staining and erosion of the teeth. in additional severe cases all the enamel is also broken. However, halide might not be the sole reason for dental enamel defects. Enamel opacities like dental pathology area unit related to different conditions, akin to deficiency disease with

deficiency of vitamins D and A or an occasional protein-energy diet. bodily function of halide once six years ancient won't cause dental pathology.The long-run bodily function of huge amounts will cause probably severe skeletal issues. The condition and its result on individuals pathology is caused by excessive intake of halide. The dental effects of pathology develop abundant previous the skeletal effects in individuals exposed to massive amounts of halide. Chronic high-level exposure to halide will cause skeletal pathology. In skeletal pathology, halide accumulates within the bone more and more over a few years. the first symptoms of skeletal pathology, embody stiffness and pain within the joints. In severe cases, the bone structure might amendment and ligaments might calcify, with ensuing impairment of muscles and pain. Acute high-level exposure to halide causes immediate effects of abdominal pain, excessive secretion, nausea and inborn reflex.

Conclusion

Extensive abstraction of groundwater for irrigation functions within the central a part of the study space has given rise to a groundwater trough. This space conjointly shows larger annual fluctuations in groundwater levels. (20) The persistence of groundwater trough even once the recharge season indicates over-exploitation condition therein half. Except for this, groundwater levels within the space typically follow the surface topography.

Fluoride in water is usually of geologic origin. Waters with high levels of halide content square measure principally found at the foot of high mountains and in areas wherever the ocean has created geologic deposits. illustrious halide belts toward land. Intake of excess halide, most ordinarily in drinking-water, will cause pathology that affects the teeth. Paradoxically, low levels of halide intake facilitate to stop caries. The management of drinking-water quality is thus crucial in preventing pathology.

The quality of groundwater is mostly quite contemporary within the hills and slope regions, whereas it's slightly salt within the plains and valleys. AN analysis of temporal changes in groundwater quality indicates that it's passionate about geophysics, rock-water interaction further anthropogenetic activities. in an exceedingly year having adequate rain, the groundwater within the cragged space, having slopes quite one %, typically shows a pointy increase in TDS once recharge, whereas majority of the wells set within the plains show a

decrease. Such clear grouping isn't determined in years of below adequate rain.The GIS assisted info system would facilitate to use spring water management practices admire, correct spring water resource management in terms of spring water quality & amount, integrated management of water, land use and also the surroundings, and to forestall spring water quality deterioration through correct observation and analysis.

Abstract

Introduction: Stature is an important biological parameter in medico-legal examination. This includes the determination of species of origin, age, sex and stature from the bones. It occurs when highly decomposed or mutilated fragments are brought to the medico-legal examination. Sometimes only the skull of the human is brought to the examination and helps in the estimation of stature. Among the common questioner of medico legal examination e.g. age, sex, race, etc, estimation of stature becomes equally important in such cases.The aim of this study was to estimate the stature of human from the head length and the head breadth.

Materials and Methods: This prospective study was done in department of Anatomy, Saveetha Dental College, Chennai located in Southern India. It was carried out in September 2015. A total of 100 young and healthy individuals comprising of 73 girls and 27 boys were selected for the present study. Anthropometric methodology:The stature and then head measurements of each subject were taken by using standard anthropometric instruments, in centimetres, to the nearest millimetre according to the technique described by Vallois.

Results: Descriptive statistics for height, head length, head breadth. (Male = 27; Female = 73).Head length: The regression equation generated showing the correlation between the height and the head length : Height = 2.306Head length + 119.324 (R2 - 0.042)Head breadth: Theregression equation generated showing the correlation between the height and the head breadth :Height = 1.701Head breadth + 136.385 (R2 - 0.010)

Conclusion: From this study, it can be concluded that the stature can be estimated from head length and the head breadth of the South Indian population.

***Key Words**: Estimation; Stature; Head Length; Head Breadth; South India*

Introduction

Stature or standing height is defined as the distance the head vertex and the standing surface.Because it provides one piece of information that may be an aid in individual identification, stature prediction occupies a central position in anthropological research and forensic identification analysis in the events of accidents, murders, genocide or natural disasters. It occurs many a times when highly decomposed or mutilated bodies or fragmentary remains of skull are brought for medico-legal examination. Sometime only skull is brought for examination and this is most common in our region wherevictims are attacked by wild animals in deep forests. In such situation it becomes difficult to identify deceased.

Since all these parts of the body and bones are not always available for forensic examination, it becomes necessary to make use of other parts of the body like head and face region. But only a few studies have been conducted on cephalo - facial region with respect to estimation of stature. In identification of human remains, forensic anthropologists help to interpret evidence pertaining to manner or cause of death. Marks on bones provide very important information's to how death occurred. With all evidence of skeleton trauma, it is imperatives recognized and distinguish among the ante mortem, perimortem (around the time of death) postmortem (after death).There are a few studies for stature estimation from skull alone. It is proved that each race requires its own formula for stature estimation. Racial and ethnic variations also exist in population of different geographical areas. Marks on the bone provide a very important information to know how the death occurred. Therefore, this study was undertaken from maxillo-facial anthropometry using head length and the head breadth and formulate regression models for this purpose.

Among the common questionnaire of medico legal examination e.g. age,sex, race, etc, estimation of stature becomes equally important in such cases. There is definitive biological correlation of stature with all the body parts such as extremities, head,trunk, vertebral column etc. There are variations in the length of limb bones relative to stature and according to race,sex, age,sideofthe body,climate, heredity and nutrition [1].Whenever the body is recovered in mutilated or fragmented state, the problem of identification of the person is difficult even by the most experienced forensic experts. The mutilation of dead body is done by a criminal who wants to destroy all the traces of identity and to facilitate the disposal of dead body. Height is fundamental to assess growth, nutrition, calculating body surface area and predicting pulmonary function in childhood.

There are a few studies for stature estimation from skull alone. It is proved beyond doubt that each race requires its own formula for stature estimation. The climate and dietary habits ofthe people of different regions of India are variable. Racial and ethnic variations also exist in population of different geographical regions. Hence opinions based on the result of studies done in one population cannot be entirely applicable to other population [2]. Many studies have been conducted on stature from percutaneous measurements of various body part including arm, leg, feet, etc [3-6]. Considering this scenario there is a need of systematic study for stature estimation from fragmented and dismembered skull remains.

Since there are few studies in the existing literature which assesses the stature of the individuals using head length and head breadth in a particular ethnicity, it warrants studies in the research focus. This can be utilized in the field of forensic odontology and it can aid in identification of individuals who have succummbed to catastrpohic incidents or genocide or natural disasters. Therefore the present study was undertaken to determine stature from maxillo-facial anthropometry using head length and head breadth in the South Indian population.

Materials and Methods

This prospective study was done in the Department of Anatomy, Saveetha Dental College and Hospital, Chennai located in Southern India. This study was approved by the Institutional Review Board of the University. It was carried out from September 2015 to December 2015. A

total of 100 young and healthy individuals comprising of 73 girls and 27 boys were selected for the present study.

Anthropometric Methodology

The stature and then head measurements of each subject were taken by using standard anthropometric instruments, in centimetres, to the nearest millimetre according to the technique described by Vallois.

1. Stature: The stature was measured in standing position to the vertex in Frankfurt plane by using anthropometric rod.

2. Head Length (HL): The distance between the glabella and farthest projecting point in the mid-sagittal plane, on back of the head (Occiput). The later is termed as the Opisthocranion. Glabella is the most forward projecting point in the midline of the forehead at the level of supraorbital ridges and above the nasofrontal suture.

3. Head Breath (HB): The greatest transverse diameter on the head is from euryon to euryon. Euryon is bilaterally paired point that forms the terminus of the line of greatest breadth of the skull. Not a fixed point but determined with calliper.

The height of the individual was measureed using a standard height measuring frame.

Results

The statistical analysis was performed using the SPSS software (Macros version). The descriptive statistics for height, head length and head breadth. (Male = 27; Female = 73) has been depicted in [Table 1].The mean measurement for height is 161.99. The maximum height of the population was found to be 185cm while the minimum height for the population was 142cm. The mean head length was seen to be 18.501, and the maximum and minimum head length was 20.9cm and 16.3cm respectively. Had length means was found to be 15.05. The maximum head breadth was 16.5cm and the minimum head breadth was 14.1cm.

Head Length

The regression equation generated showing the correlation between the height and the head length :

Height = 2.306Head length + 119.324 (R^2 - 0.042)

Head Breadth

The regression equation generated showing the correlation between the height and the head breadth :

Height = 1.701Head breadth + 136.385 (R^2 - 0.010)

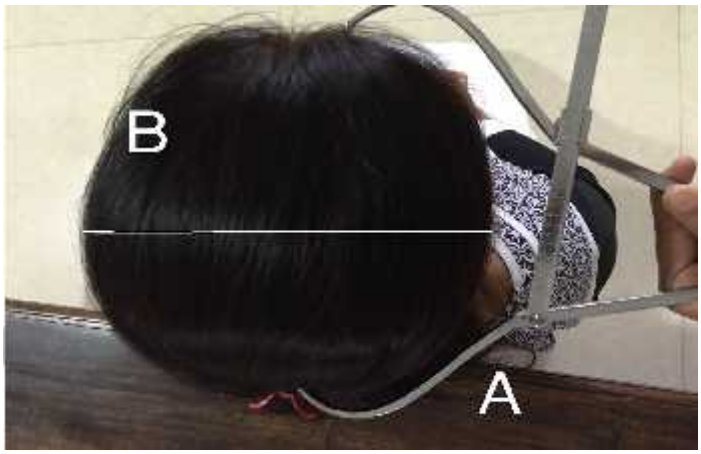

Figure 1: Measurements using a spreading calliper

A : Head Length

B: Head Breadth

Table 1 : Descriptive statistics for height, head length and head breadth

Measurement	Mean (cm)		Maximum (cm)	Minimum (cm)
Height	161.99		185	142

Head length	18.501		20.9	16.3
Head breadth	15.05		16.5	14.1

Discussion

An accurate estimation of stature for the purpose of identification has a significant forensic importance. The findings of our study. Several studies reported various statures for other ethnic groups and nations across the world. Mean stature of Ijaw males is 175.1 cm and that of Ijaw female is 166.3 cm, while the mean stature of Ikwerre male is 164.5 cm and that of Ikwerre female is 156.4 cm [7]. Adult Urhobo male has an average height of 172.5 cm and an adult Urhobo female has an average height of 161.7 cm [8]; while the mean stature of adult Ibo male is 167.6 cm and that of Ibo female is 163.2 cm [9]. The mean stature of Turkish adults is 174.4 cm (males) and 160.9 cm (females); that of Sri Lankans is 170.1 cm (males) and 157.6 cm (females) [10]; male Montenegrins are 183.2 cm tall while female Montenegrins are 168.4 cm tall making Montenegro the second tallest nation in the world after Netherlands (male 183.8, female 170.3) [11].

Mean stature for populations of adults, therefore, varies from minimum values for the Efe Pygmies of Africa at 144.9 cm for men and 136.1 cm for women to the maximum values for the Dutch of Europe at 184.0 cm for men and 170.6 cm for women [7].Though works concerning estimation of stature from long bones as well as from certain body dimensions have been put forward for some of the Indian population, works concerning estimation of stature from cranial dimensions are scanty. Hence present study is an attempt to estimate stature from head length and head breadth. And also tried to final out any correlation between stature and head length & head breadth. This is study is very unful when only skulls is bought for examination. The findings in the present study indicate that Head length and Head breadth are positively and significantly correlated with stature similar observations on stature have been reported in other races [12].

Stature Head length and head breadth were significantly greater in males when compared with females which is in occurrence with Bardale and Dixit [12] found correlation coefficient of head breadth with height as 0.26 which was not coincide with our study (0.053) and standard error of estimate for regression formula on head breadth was 6.40 which is similar to our study (6.80). For female the correlation coefficient of head breadth with height was 0.23 and standard error of estimate was 5.81. The values of SEE and r for females are very much similar to our results. Study onmaleGujjarsofIndia by Kewal Krishnan [13] showed that correlation coefficientfor head breadth in females was found to be 0.682 and SEE was 4.792. The regression equation given by themforstature estimation inmalesis 98.056 + 5.320 x Maximum head breadth. For highly correlated variates, regression equation can become practically useful for prediction and they are widely used in reconstruction formulae for stature, from the measurements of certain long bones [14].

Various workers have shown significant correlation between height and different parts of the body. Singh and Sohal, Jit and Singh have shown a significant correlation between height and length of clavicle. Charnalia, showed the significant correlation between height and foot-length, where correlation coefficient was 0.46. Athawale, derived a regression equation between total height and forearm bones. Shroff and Vare, have also derived the height from the length of superior extremity and its segments. It is stated that the racial characters are best defined in the skull. As a result cranial dimensions constitute one of the most important characters for determining the racial difference.

Variety of non-metric and metric parameters has been utilized in the assessment of ethnic and gender differences in cranio-facial morphology. The non-metric parameters are subjective as no quantitative techniques are devised. On the other hand, features that can be expressed as actual measurements, like cranial dimensions, provide more objective racial and gender diversity assessment of the crania. Correlation coefficients between the total height and head length among population of Rajasthan were found to be statistically significant and positive indicating a strong relationship between the two parameters. Previous studies have shown correlation coefficients of 0.627, 0.53, & 0.52 between head length and height, whereas in the present study it was 0.94 for males and 0.85 for females which is suggestive of strong positive correlation between these two parameters. Regression equations for their respective population were also derived by previous workers. Regression equations for stature prediction were formulated using head length and estimated statures in present study for study population and were compared with

the actual statures to check the accuracy. The results further confirmed that head length provides an accurate and reliable means in stature prediction. In forensic examinations and anthropological studies, prediction of stature from incomplete and decomposing cranial remains is vital in establishing the identity of an unknown individual. Therefore, formulae based on the head length provide an alternative stature predictor under such circumstances. The cranium has easily identifiable surface landmarks making the measurements possible even in compromised conditions.

Stature is one of the most commonly used criteria in studies on body structure [15]. Measurement of body height is important in many settings: it is an important measure of body size and gives an assessment of nutritional status as well as an important measure of determination of basic energy requirements, standardization of measures of physical capacity and adjusting drug dosage, and evaluation of children's growth, prediction and standardization of physiological variables such as lung volumes, muscle strength, glomerular filtration and metabolic rate [16]. It is also common knowledge that exact body height cannot always be determined through direct measurements because of various deformities of the extremities or in patients who have undergone amputations or similar injuries. Measuring stature can also be difficult in physically and mentally frail nursing home patients, e.g. patients that are wheelchair-bound or bedridden and those with osteoporosis, sequelae after hip fractures, or stroke. In such circumstances, an estimate of body height has to be derived from other reliable anthropometric indicators important and useful anthropometric parameters which is seen.

There is no data in literature to compare the correlation coefficients between age-height, age head length, age-head breadth and age- head height. The differences in relation to cranial dimensions observed in males and females may be used in determining sex and may be due to populations of different geographical areas.

Sexual dimorphism is an important component of the morphological variation in biological populations. The sex divergence in cranial morphometry observed in present study supports the previous observations. As rate of skeletal maturity in males and females vary during the course of growth and development, there is need for alternative formulae for genders.

In forensic examinations and anthropological studies, prediction of stature from incomplete and decomposed cranial remains is vital in establishing the identity of an unknown individual. Therefore formulae based on the cranial dimensions provide an alternative stature predictor

under such circumstances. Data can be used in conjunction with other anthropological techniques to sex and race determination of unknown individuals.Variety of factors such as age, race, sex and nutritional status affect development and growth and therefore differentnormograms are required for different populations. The present study has documented such norms for cranial dimensions and presented gender specific linear regression lines for stature and age prediction in adult Indian population. Thus population, sex and age specific regression lines will be of immense use in medico-legal, anthropological and archaeological studies.

Frutos conducted a study based on 118 complete humeri from Guatemalan forensic sample. He studied six anthropometric dimensions and concluded that the classification accuracies for the univariate functions range from 76.8% to 95.5% and for stepwise function procedure was 98.2%. Kemkes-Grottenthaler 60 evaluated the reliability of patella anthropometry in sex determination in a material from different archaeological samples [17]. He achieved almost 84% accuracy in sex determination. Patil and Mody conducted a lateral cephalometric study on central Indian population to devise a model for determination of sex. They took ten measurements on the radiographic cephalograms of 150 normal healthy individuals and determined sex by discriminant function analysis.

Conclusion

We conclude that the stature can be estimated from head length and the head breadth. Of the South Indian population. Besides this, age of the individual can also be estimated through regression lines using data on cranial dimensions. Thus data provided in the present study will of paramount importance to anthropologists to find racial differences when only parts of deceased or Indian anywhere in the world are available and may be key to sex determinatione can be estimated from the head length and the head breadth.

Abstract

Introduction: To investigate and compare the accuracy of edentulous stock trays and extension of alveololingual sulcus. In this study, 15 complete edentulous patients were evaluated to check accuracy of the impression trays to the extension of alveolingual sulcus in the mandibular arch in the patients. Using k-file, extension of alveololingual sulcus (anterior, middle and posterior) is measured in patient's mouth intraoral. The lingual extension of mandibular edentulous stock tray in anterior, middle and posterior was also measured and then compared to the patient's alveololingual sulcus extension.

Material and Method: In this pilot study 10 completely edentulous patients in both genders, who attended outpatient clinic in Saveetha dental college and hospitals were evaluated. K-file with a stopper and the metal scale is used to measure the extensions. Mouth mirror is used to retract the tongue from the area of interest. Patients were instructed to open their mouth and protrude their tongue so that it was ¼ inch ahead of the upper lip

Result: In this study, 15 complete edentulous patients were evaluated to check accuracy of the edentulous impression trays to the extension of alveololingual sulcus of the mandibular arch in the patients. Using k-file, extension of alveololingual sulcus (anterior, middle and posterior) is measured in patient's mouth intraoral. The lingual extension of mandibular edentulous stock tray in anterior, middle and posterior was also measured and then compared to the measured patient's alveololingual sulcus extension values

Conclusion: This study was taken to evaluate and compare the lingual extension of the mandibular edentulous stock trays to the extension of alveololingual sulcus in patients.

Key Words:*alveololingual, K-file, edentulous, impression trays, lingual extension*

Introduction

In the field of prosthodontics, retention and stability are two major concerns for complete denture. The objectives of impression making are to capture the entirepotential denture bearing surface and tissues to provide retention, support and stability for the denture under function. Impression making for complete dentures may be categorised as 1)Primary impressions and 2) Definitive impressions.(1)The basic function of primary impressions for complete dentures is to outline support. These also recommend the practice of using rigid stock trays, modified as necessary to 'fit the form of the denture-bearing area'. The tray is the foundation of an accurate impression.Over-large trays will causepatient discomfort and the likelihood of the incorporation of tissue folds. Under-sized trays will result in problems for the technician making the customised trays on undersized primary casts. The clinician will experience problems as undersized primary impressions commonly result in inadequate definitive impressions and these may result in support and stability problems in the processed denture.Recent studies indicate that flawed mandibular impressions account for the majority of denture problems in the mandible. In most of the case mandibular impressions tend to be 'short' of the retro molar pads and do not accurately record the functional forms of the floor of the mouth and the retromylohyoid fossae.(3) These deficiencies tend to result in an unstable denture.This study, evaluate and compare the lingual extension of the mandibular edentulous stock trays to the extension of alveololingual sulcus of the patients.(4) A **complete denture** is a removable appliance used when all teeth within a jaw have been lost and need to be prosthetically replaced. In contrast to a partial denture, a complete denture is constructed when there are no more teeth left in an arch, hence it is an exclusively tissue-supported prosthesis. A complete denture can be opposed by natural dentition, a partial or complete denture, fixed appliances or, sometimes, soft tissues.Retention in removable prosthodontics is defined as the resistance to vertical dislodgment that can arise from either muscular forces or physical forces. It can be gained from three different surfaces of the denture Occlusal surface, surface, Impression surface.(5)

Edentulous Stock Tray

The need to make accurate impression is fundamental to the practice o f Prosthodontics. This necessitates the dental clinicians to make careful assessment of the tissues to be recorded in the impression, type of impression trays, impression material and the techniques to be used. stock metal trays are the most commonly used impression trays The selected stock tray must cover all denture bearing area in over-extended manner. A primary cast with good coverage of proposed denture bearing area gives freedom of using any spacer design with tissue stops within the custom impression tray, thus dictating impression technique and allowing better final impressions.(6)The objectives of the primary impression are to record all the areas to be covered by the intaglio surface of the dentures and the adjacent landmarks with an impression material which is accurate and incorporates the minimum tissue displacement.(7)The use of alginate in an oversized perforated tray, where as others recommended use of impression compound by using a stock tray. Complete dentures certainly help in the control and breaking up of a bolus of food, but their chewing efficiency is considerably lower than that of natural teeth. This is due to natural teeth being firmly attached to the surrounding bone whereas dentures are merely sitting on the mucosa and thus must be actively controlled by the patient; the pain threshold of the denture-bearing mucosa is relatively easily exceeded so that the biting force, which is closely correlated with chewing efficiency of complete dentures, is reduced and may be only a sixth of that of dentate patients.(8,9)

Alveololingual Sulcus

The space in the floor of the mouth between the base of the tongue and the alveolar ridge, on each side extending from the frenum of the tongue back to the retro molar wall. It serves as a landmark for construction of denture. Achieving correct positioning of the lingual borders of the mandibular denture has taxed the abilities of generations of prosthodontists. (10) Entire border of the denture should be in contact with so displaceable tissues to complete the peripheral seal and achieve satisfactory stability and retention. Covering the maximum area of the denture foundation is one of the prime requisites to improve support and stability. Registering the exact tissue details under physiologic pressure relates to dentures being stable in function. Accurate border moulding within physiologic limits accomplishes the most desirable border seal. When deciding upon a course of treatment for an elderly patient, one

must always have the original complaint at the forefront of one's mind and plan a programme of care that can be achieved in the particular circumstances. For example, the request to see the patient may come from a relative who has become increasingly embarrassed that dentures are not being worn on social occasions. The health of the patient may have deteriorated to such an extent that successful control of a new lower denture is clearly out of the question.(11,12) It may be concluded that realistic treatment is the provision of an upper denture only, which will be worn for appearance's sake rather than for function. In such circumstances, it can be argued that the dentist is treating the relative as well as the patient, a course of action that surely is entirely justified. Although this particular illustration may be thought of as an extreme one, it is by no means uncommon in long-stay care homes and does serve to make the point that successful treatment is the 'art of the possible'.(13)

Complete denture

Most edentulous people over the age of 65 are wearing dentures that are more than 10 years old and, as a result, mucosal changes are present in between 44% and 63% of cases. The need for treatment, based on clinical judgement, suggests that 40% of 5-year-old dentures and 80% of 10-year-old dentures should be replaced. However, the picture is not that simple. Need can be measured in a variety of ways: 'Normative need' is the need defined by expert or professional opinion. 'Felt need' is the patient's subjective desire.(14) 'Expressed need' is recorded when the 'felt need' is activated through the patient seeking treatment. One estimate of 'normative need' has already been described. Others indicate that 70–85% of elderly people's dentures require attention and that such need far exceeds the 'expressed need'. Elderly people are likely to consider that treatment is required as a result of experiencing pain, difficulty in chewing, a deteriorating appearance, or because the existing dentures are broken or have been lost. However, the 'felt need' may not be activated for a variety of reasons, including the following: The dental problem is low on the list of priorities compared with other problems. (15,16)Inertia on the part of the patient.Ignorance of available services. Fear of treatment that may be required. It is important to remember that a large proportion of today's edentulous patients experienced dental treatment in less sophisticated times when pain was a frequent accompaniment. Inability to travel to a surgery because of ill health or

problems of transportation. A feeling that nothing can be done anyway and that the dental problem is just one of the inconveniences of old age, Finance.(17)

Material and Method

Patient

In this pilot study 10 completely edentulous patients in both genders, who attended outpatient clinic in Saveetha dental college and hospitals were evaluated.

Inclusion Criteria and Exclusion Criteria

The inclusion criteria patient should be completely edentulous with well-rounded residual ridge. The patients with congenital and acquired maxillary& mandibular defects, patients with severely resorbed mandibular edentulous ridge are excluded.

Methodology

K-file with a stopper and the metal scale is used to measure the extensions. Mouth mirror is used to retract the tongue from the area of interest. Patients were instructed to open their mouth and protrude their tongue so that it was ¼ inch ahead of the upper lip. Then the instrument is placed inside the patient's mouth so that extension of the floor of the mouth in anterior, middle & posterior region is measured under functional position. With the use of k-file and metal scaleanterior, middle & posterior region of the mandibular edentulous stock trays which is currently available is also measured.

Results

In this study, 15 complete edentulous patients were evaluated to check accuracy of the edentulous impression trays to the extension of alveololingual sulcus of the mandibular arch in the patients. Using k-file, extension of alveololingual sulcus (anterior, middle and posterior) is measured in patient's mouth intraoral. The lingual extension of mandibular edentulous stock tray in anterior, middle and posterior was also measured and then compared to the measured patient's alveololingual sulcus extension values. In table1 shows

measurements of the alveololingual sulcus extension recorded in the patients intraorally.The entire patient showing posterior region of the alveololingual sulcus extension is higher than the middle and the anterior region comparatively. The extension of the middle region of alveololingual region is lower than the anterior and posterior region. Table 2 shows the measurement of the impression trays in size. Impression trays with the size L2 & L3 are used in the patients. In both the trays lingual flange extension, in the posterior region is higher than the middle and anterior region. The mean value of lingual extension of the all patient were evaluated and compared with impression tray size. Except the middle region of the impression tray, anterior and posterior are lesser or equal to the patients lingual extension. (18)The middle region of the impression trays shows higher than the patients average lingual sulcus extension.

Discussion

According to the patient's mandibular alveololingual sulcus extension, length of the posterior region is slightly greater than middle and anterior part. There are different types of tray sizes available, for lower it is L1, L2, L3 and L4. Mostly L2 and L3 are used. The key step to a successful final impression is the selection of proper tray. The distal end of alveololingual sulcus is lateral throat form. It has an great influence on fabrication of complete dentures. The extension of the denture in this area can resist horizontal forces and increase border sealing.

The length and the thickness of the flange in the space are different depending on the tonicity, activity and anatomic attachments of the adjacent structures. Except the middle region of the impression tray, anterior and posterior are lesser or equal to the patient's lingual extension. The middle region of the impression trays shows higher than the patients average lingual sulcus extension. It will result in over extended impression and sometimes cause discomfort to the patients.The excess length of the tray in the lingual region will produce an artificially stretched and thinned impression of the lingual sulcus which will tempt the dental technician to finish the denture short in that region thus losing valuable extension and bracing for the denture. (19,20)

In 1994 OGDEN.A. R, SIDDIQUE, BASKER .R M: study compared the sizes of patient's edentulous arches with the shape range of stock trays. It is concluded that even with tray modification. It is almost impossible to obtain an accurate impression of the shape of the all-important sulcus region.(21)

Conclusion

Primary impression in a stock tray should be regarded as a mean of producing a cast on which a more accurate working impression can be modified. Most of the impression trays are not sufficiently standardized. It is important to assess the size of the stock trays, not only the coverage of the retro molar pad and also lingual sulcus extension. (21)This enables the width of the tray to record the functional width of the sulcus. Recent guidelines from the British Society for the Study of Prosthetic Dentistry recommend to practice of using rigid stock trays, modified either by extending the tray or by trimming the tray extension as necessary to fit the form of the denture bearing area.

Abstract

Introduction: Dental education is at a critical state due to advances in health care delivery system. In dentistry one can gain extensive amount of knowledge only when they are students.The aim of this study is to assess the Internship programme of undergraduate students of a private dental college in Chennai.

MaterialsandMethod: A cross-sectional study was conducted among undergraduates. A pretested questionnaire was used to assess the internship experience like critical thinking knowledge,problem solving skills .senseof responsibility,creativity,professionalattitude, appearances, quality of work and ethics. Descriptive were analysed.

Results: It shows that about 72.3% of interns were satisfied about their internship achievements.

Conclusions: The study concludes that the internship programme have built in the clinical competency of the interns.

Key Words*: internship, self evaluation, learning, communication, curriculum*

Introduction

Dental curriculum changes dynamically hence it needs to be monitored and reconstructed according to the needs of the student, community and profession, otherwise it becomes stagnant.According to Shetty V.B, a good curriculum should always restructures itself and should receive feedback from all stakeholders. [1] The dental education is at a critical stake due to the advances and changes in the health care delivery system. There is a wide belief that the dental students are not satisfied with their experience in the dental colleges which may be due to the stressful environment. [2]Psychological stress or distress has long been regarded as an important influence on the learning and performance of the students. It serves as a motivation to some portion of the student community and for the rest it has adverse negative effect on their studies, health and personal lives. [3]

Being a consumer of the dental programme, the students view must be considered by the curriculum evaluation committee while updating the dental curriculum [4]. A self assessment can be conceived as an ingrained habit or trait to reflect an individual. Students of dental profession are bright; goal oriented and is reflective, sightful and consistent in academic and in assessing their skills and ability. [5].Hence the study was designed to analyse the perception of the interns about the present scenario of dental education, clinicaltrials, teacher-student relationship, professional outlook and patient care.

Materials and Method

A pre-tested structured questionnaire were given to 65 students of Saveetha Dental College and Hospitals, Chennai who were undergoing the internship programme. The feedback of the interns regarding the questionnaire were gathered and the data collected were entered for further evaluation. Evaluation of the data was done and the output was obtained.

Result

The results showed an overall satisfaction in achieving the internship roles and responsibilities along with performance(table 1), organisation and working environment(table 2) and finally the academic portfolio and extra curricularsactivites(table3).

Table 1: Internship Roles and Responsibilities with Performance

Items	Strongly disagree %	Somewhat disagree %	Neither agree nor disagree %	Somewhat agree %	Strongly agree %
Achievement of internship objectives	4.6	6.2	16.9	53.8	18.5
Demonstration of communication skill	3.1	13.8	6.2	49.2	27.7
Application of classroom knowledge	4.6	7.7	20.0	40.0	27.7
Critical thinking and problem solving skill demonstration	7.7	7.7	15.4	49.2	20.0
Professional appearance	4.6	4.6	9.2	53.8	27.7
Response to supervision and criticism	6.2	9.2	20.0	44.6	20.0
Self sufficient, independent as well as a team worker capacity	1.5	1.5	15.4	40.0	41.5
Exhibition of responsibility and dependability	3.1	7.7	7.7	50.8	30.8
Exhibition of positive attitude towards work and co workers	3.1	4.6	7.7	36.9	47.7
Exhibition of professional attitude to behave	6.2	13.8	6.2	49.2	24.6

ethically					
Sensitive to diversity	6.2	12.3	23.1	40.0	18.5
Adaptation to changing circumstances	3.1	3.1	16.9	47.7	29.2
Sufficient quantity and quality of work production	6.2	6.2	18.5	40.0	29.2
Demonstrated awareness of strength/ weakness	1.5	9.2	7.7	52.3	29.2
Was comfortable handling all assigned responsibilities	6.2	0.0	20.0	49.2	24.6

Table 2: Organisation and working environment

Title	Strongly disagree %	Somewhat disagree %	Neither agree nor disagree %	Somewhat agree %	Strongly agree %
Providence of sufficient orientation to its mission, purpose, culture,policies and practices	10.8	1.5	13.8	56.9	16.9
The work environment was stimulating	7.7	12.3	13.8	46.2	20.0
The organisation invited me to provide feedback and input on the work in which I was engaged and to discuss	13.8	10.8	16.9	43.1	15.4

organisational matter					
The work was challenging	7.7	3.1	12.3	44.6	32.3
The internship tasks and experiences helped to meet the learning goals and objectives	4.6	1.5	16.9	49.2	27.7
Providence with access and insight into a variety of activities to contribute to the learning	4.6	3.1	15.4	50.8	26.2
Was conscious of my needs as an intern and made clear the task responsibilities	7.7	1.5	18.5	50.8	21.5
Assigned an appropriate amount of work	7.7	10.8	18.5	41.5	21.5
Discussed ways by which learning objectives could be achieved	7.7	4.6	27.7	43.1	16.9
Providence of regular assistance and willingness to answer the queries regarding work setting and specific tasks	4.6	7.7	20.0	50.8	16.9

Table 3: Academic Portfolio and extra curricular activities

Title	Strongly disagree %	Somewhat disagree %	Neither agree nor disagree	Somewhat agree %	Strongly agree %
Academic coursework provided preparations of	6.2	3.1	16.9	46.2	27.7

professional knowledge and skills					
Comparison helped in modulating the internship programme	7.7	10.8	18.5	44.6	18.5
Usage of CAD CAM, RVG and advances record management system was useful	7.7	10.8	10.8	41.5	29.2
Outreach program helped to explore more unknown problems	4.6	7.7	18.5	47.7	21.5
Participation in conferences, seminars and presenting scientific papers and posters provided insight	3.1	3.1	18.5	46.2	29.2
Research work helped in career building	9.2	7.7	24.6	35.4	23.1
Library provided adequate resources for various academic and research purposes	9.2	13.8	20.0	40.0	16.9
Usage of wifi and ipad was beneficial	9.2	10.8	10.8	41.5	27.7
No. Of clinical procedures provided adequate training and professional skills	10.8	9.2	13.8	43.1	23.1
UTSAV provided platform	6.2	6.2	6.2	24.6	56.9

to exhibit hidden talents					

Discussion

It is very important to consider the perspective of graduating dental students regarding their curriculu, motivation and support. Also it is necessary o assess their internship experience like critical thinking knowledge,problem solving skills.sense of responsibility,creativity,professional attitude, appearances, quality of work and ethics.

The study show the various perceptions of the interns of a private dental institution should that there was overall satisfaction in acheievong the internship roles and responsibilities along with performance. It also gives us an insight of the strengths and weakness of the current curriculum of that dental college which is monitored regularly.

Table 1 shows that about 49.2% of studnts have necessary communicaton skills. This is in accordance with the study conducted by Lanning S.K et al who quoted that, communication skills learned in the clinical setting, helps in providing a formal approach towards the patient and it is more efficient in enhancing the students confidence[3]. Also 49.2%of the interns have the ability of critical thinking and problem solving skills. About 50.8% of interns exhibit responsibility and defendabilty. About 49.2% were comfortable in handling all the assigned responsilities.

More than 40 percent of the students expressed that, they were able to apply their theoretical knowledge in their clinical practice which is higher than a similar study conducted by Ashri N in King Saud University,Riyadh.[4].

The internship tasks and responsibilities were handled comfortably by about 52.3 percent of the students which reflects that the students have gained adequate confidence to meet their goals and to understand their strength and weaknesses.

A study conducted by Kumar S in Rajasthan highlighted that students had stress due to the fear of their clinical in charge and the environment provided by the faculty to them during their clinical training [8].

The study by Chaudhary S mentioned that the way the practitioner carries himself influences the patients image of him or her[9]. Nearly 53.8 percent of the interns believed in maintaining a good professional appearance.

Nearly 40 percent of the students were elated about being a self sufficient worker as an individual as well as a team worker. A study in UK by Evans J showed the need for the development of a positive attitude towards inter professional education which will help in maintaining a good team work with the technicians and their colleagues which will lead to a better collaborative practice.[10]

This was furtherillustrated in a study done by Leisnert L in Sweden where the students responded that patient needs to be approached holistically which should be a permanent part of education.[11] About 47.7 percent of the students appeased positive attitude towards their co workers. This helps them to respect each other's role in providing care for the patient.

The Association of American Medical colleges considers ethical responsibility to self and others, reliability, adaptability and dependability as the crucial for effective professional behaviour.[12] Being an intern student who is going to be exposed to private practice soon needs to be aware and exhibit the same. About 50.8 percent of the students exhibited responsibility and dependability during the course work.

Nearly 50 percent of the students exhibited professional attitude to behave ethically and 40 percent of the students were sensitive to diversity at the working environment. Diversity during the clinical practice includes the difference in gender, socioeconomic status, religion of the co workers and patients.

About 47.7 percent of the students were able to adapt to the changing circumstances and 46.2 percent of the interns believed that the working environment was stimulating for them to perform from better to best.

Table 2 shows that about 56.9% agree that the working environment provides sufficient orientation to its mission , purpose , culture ,polices and practices . About 50.8% of the interns were stiulated by regular assistance and willingness of the faculty to clear their queries regarding specific tasks. Attitude of the faculty towards the intern helped in modulating their perspective of achieving their objectives.

Nearly 43.1 percent of the interns were satisfied in providing feedback and discussing organisational matters. Asimilar study was done by Curtis D.A in University of California which the organisation invited its students to a provide a self assessment feedback of preclinical examinations.[13]

The number of clinical procedures done by the interns provided them with adequate training and professional skills. This was strongly agreed by 66.1 percent of the students while in a similar approach done in Riyadh reported only 59.8 percent of its students were satisfied with the quantity and quality of work produced by them in different branches of dentistry that helped them in becoming a self sufficient clinician at the undergraduate level.[4]

Adding on to the work production, selection of proper techniques and giving proper care provides a good orientation to their mission as a clinician. This was also sighted in a study by Marchan S.[6]

A major portion of the study population agreed that the work was challenging and will help them in improving their performance and observational skills during their clinical practice.

Table 3 shows that about 41.4% of the iterns were highl elated with the usage of facilites like like CAD-CAM, RVG, TOUCH ON CLOUD, DENTAL COLLEGE RECORD MANAGEMENT SYSTEM USING IPAD.[15,16,17,18,19]Also it has newer methods of learning and opens out vast areas of resources. These revolutionary technologies enhance the dental practise and education.[18'19]The ciruculam also provides oppurtunites to add credentials to their profile by participating in conferences and seminars. This enourages the to tackle different obstacles that arise while engaged in research work.

A library is an important aspect of every institution but the usage and the importance of it is lacking in almost all the students.Only 40 percentage of the students realised the benefits of the adequate resources found in the library for various academic and research oriented purposes where as in a parallel study done by Shetty V highlighted its grief of only 35 percent of its students were satisfied with the library resources.[1]

Apart from the academic mission and orientation, the institution also provides an equal opportunity for its students to showcase their talents. By providing a platform for these talents to its students the institution will be able to explore ways to reduce stress among them and increase the efficiency of work produced by them.

Conclusion

This study has investigated the internship program of a private dental college in Chennai. Feedack of the interns highlights the success of the ciriculum. The enormous work produced by the interns helps to adapt to changing environment and overcome the stress. Patients satisfaction, time management and potent assessment becomes fruitful with efficient communication skills. The strength of the current program were a provision to critical thinking , problem solving skills , exhibiting responsibility , providing good working environment and revolutionary computer technologies.

Evaluation of Patterns of Third Molar Impaction in Chennai Population

Divyadharshini V[1], Nithya Jaganathan[2], Dinesh Prabu[3]

Graduate student[1,] Reader[2], Department of Oral Pathology,

Senior Lecturer[3], Department of Oral and maxillofacial Surgery

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Introduction: Tooth impaction is a pathological situation in which a tooth cannot, or will not; erupt into its normal functioning position, unless facilitated by treatment [1]. One of the important causes for third molar impaction is the inadequate space in the arches for the molars to erupt. Although many impacted teeth appear asymptomatic, they are considered as potential source of trouble. The purpose of the study was to investigate and analyse the prevalence and pattern of third molar impaction in adults between 18-35 years of age who attended a Private Dental College in Chennai, Tamil Nadu.

Materials and Methods:A total of 430 orthopantomograms (OPG) of patients ranging in age from 18 to 35 years were collected, of which 200 OPG's had third molar impaction. . The pattern of third molar impaction, their frequency, levels of eruption, and their angulations were evaluated. The position of impacted third molar was classified according to Pell & Gregory and Winters classification.

Result: Two hundred of the 430 OPG showed at least one impacted third molar. In males, theimpacted third molars were more likely to occur in the mandible (81.4%) than in the maxilla (30.1%). In females, the impacted third molars were more likely to occur in the mandible (78.2%) than in the maxilla (43.7%). Mesioangular (42.8%) impactions were more likely to occur in the mandible and Vertical (58.8%) impactions were more likely to occur in the maxilla. Level B impaction was themost common in both maxilla (77.1%) and mandible (84.3%).

Conclusion: Mandibular third molar has a high prevalence of impaction in the Chennai population with nosex predilection.

Key Word: *Chennai, Impaction, Population, Pattern,Third molar.*

Introduction

Impaction was derived from Latin word which is defined as the cessation of eruption of tooth caused by a clinically and radiographically detectable physical barrier in the eruption path or by an ectopic position of the tooth. Any tooth may be impacted, but certain ones are more commonly affected than others. Maxillary and mandibular third molar and the maxillary cuspids are more commonly impacted followed by premolars and supernumerary teeth. Generally, third molars have been found to erupt between the ages of 17 and 21 years [2, 3]. According to Elsey and Rock [4] impaction of the third molar is the most common and accounts to 98% of all impactions. The incidence of impaction of maxillary and mandibular third molar varies widely and is reported to be in a range of 22% and 18% respectively. Of the third molars, the mandibular teeth are more apt to exhibit severe impaction than the maxillary teeth. This can be attributed to the pattern and development of face and facial bones, tooth size and the eruption pattern.

Etiology of permanent teeth impaction includes several systemic and local factors. Cleidocranial dysplasia, Down syndrome, endocrine deficiencies (hypothyroidism and hypopituitarism), febrile diseases, and irradiation, are some of the systemic factors that may influence impaction of permanent teeth [5, 6]. Local factors include prolonged deciduous tooth retention, malposed tooth germs, arch-length deficiency, supernumerary teeth, odontogenic tumours abnormal eruption path, and cleft lip and palate [7-9].

Wisdom teeth become impacted when there is not enough room in the jaws to allow for all of the teeth to erupt into the mouth. Because the wisdom teeth are the last to erupt, due to insufficient room in the jaws to accommodate more teeth, the wisdom teeth become stuck in the jaws that are impacted. Genetics plays an important, albeit unpredictable role in dictating jaw and tooth size and tooth eruption potential of the teeth. Some also believe that there is a evolutionary decrease in jaw size due to softer modern diets. The formation of wisdom teeth differs by population, ranging from practically zero in Tasmanian Aborigines to nearly 100% in indigenous Mexicans. The difference is related to the PAX9 gene.

Wisdom teeth communicating with the mouth cause localized pain, swelling and bleeding of the tissue overlying the tooth. This tissue is called the operculum and the disorder called pericoronitis which means inflammation around the crown of the tooth. Low grade

chronic periodontitis commonly occurs on either the wisdom tooth or the second molar, causing less obvious symptoms such as bad breath and bleeding from the gums. As the teeth near the mouth during normal development, people sometimes report mild pressure of other symptoms similar to teething.

The aim of the present study was to evaluate the pattern of third molar eruption radiographically and correlate it with the gender of an individual. The study also aimed to evaluate the angulation and level of impaction among Chennai population.

Materials and Methods

The study was conducted on archived orthopantomogram radiographs available in the Oral Medicine and Radiology department of patients who were subjected to radiographic examination for other dental problems. The radiographs were exposed with Orthophos Sirona XG 3D hybrid machine. The exposures were taken at 60-64 kvp with 1-2 mA. Two hundred orthopantomograms (OPG) of patients aged 19years and older and their related data were selected from the records. Of which 113 belong to males and 87 belong to females. OPG of patients younger than 19 years; a history of any dental extraction; orthodontic treatment or dento alveolar trauma; incomplete root formation of the third molars; any pathological dento alveolar condition; any craniofacial anomaly or syndrome such as Down syndrome; cleidocranial dysostosis; and the presence of incomplete records or poor quality OPG were excluded from the study. Patient's OPG were evaluated to determine the third molar status.

Third molar was considered impacted if it was not in functional occlusion. The level of impaction was determined according to the relationship of the CEJ of the third molar relative to the alveolar bone level (Table 1). The angulations was assessed by measuring the angle formed between the long axis of third molar relative to the long axis of the second molar (Table 2).

Table 1: Pell and Gregory classification of levels of third molar impaction based on its position in bone

Level	Definition
Level A	Not buried in bone
Level B	Partially buried in bone
Level C	Completely buried in bone

Table 2: Winters classification of level of impaction based on angulation of third molar

Level of impaction	Angulation of third molar to second molar
Vertical impaction	10o to -10o
Mesioangular impaction	11o to 79o
Horizontal impaction	80o to 100o
Distoangular impaction	-11o to -79o

Results

The study evaluated 430 orthopantomograph. Out of these 230 were eliminated as it did not show at least one impacted teeth. A final set of 200 OPG's were taken for evaluation. Among the 200OPG's 113 (56.5%) were males and 87 (43.5%) were females. The number of impacted and non-impacted third molars in maxilla and mandible was evaluated in males and females. The impacted third molars were also evaluated based on angulation and level of impaction in maxilla and mandible.

Number of Impacted and Non-Impacted Third Molar in Males and Females

Maxilla

In maxilla, the number of impacted third molars in male was 68 (30.1%) and in female was 76 (43.7%). The total number of impacted third molars in maxilla was 144 (36%). The number of non-impacted third molars in male was 158 (69.9%) and in female were 98 (56.3%). The total number of non-impacted third molars was 256 (64%). There is significant difference between impacted and non-impacted third molars in males and females ($p<0.05$). (Table 3)

Table 3: Impacted teeth among males and females in Maxilla

	Male		Female		Total		P-value
	N	%	N	%	N	%	

Impacted teeth	68	30.1	76	43.7	144	36	0.005
Non impacted teeth	158	69.9	98	56.3	256	64	

Mandible

In mandible, the number of impacted third molars in male was 184 (81.4%) and in female were 136 (78.2%). The total number of impacted third molars in maxilla was 320 (80%). The number of non impacted third molars in male was 42 (18.6%) and in female was 38 (21.8%). The total number of non impacted third molars was 80 (20%). The results were not statistically significant ($p<0.05$). (Table 4)

Table 4: Impacted teeth among males and females in Mandible

	Male		**Female**		**Total**		**P-value**
	N	**%**	**N**	**%**	**N**	**%**	
Impacted teeth	184	81.4	136	78.2	320	80	0.420
Non impacted teeth	42	18.6	38	21.8	80	20	

Angulation of impaction

The angulation of impaction of right and left third molar in maxilla and mandible was determined using table 5 and table 6.

Maxilla

The most common angle of impaction in right maxillary third molar was vertical (53.8%). The most common angle of impaction in left maxillary third molar was vertical (63.8%). These data's suggest that the most common angle of impaction in maxilla is vertical (58.8%).

Table5: Angulation of Impaction in Maxilla

	HORIONTAL		VERTICAL		DISTOANGULAR		MESIOANGULAR	
	N	%	N	%	N	%	N	%
18	1	1.3	43	53.8	23	28.8	13	16.3
28	1	1.7	37	63.8	14	24.1	6	10.3

Mandible

The most common angle of impaction in right mandibular third molar was mesioangular (42.3%). The most common angle of impaction in left mandibular third molar was mesioangular (43.3%). These datas suggest that the most common angle of impaction in mandible is mesioangular (42.8%).

Table 6: Angulation of impaction in Mandible

	HORIONTAL		VERTICAL		DISTOANGULAR		MESIOANGULAR	
	N	%	N	%	N	%	N	%
38	46	29.3	43	27.4	0	0	68	43.3
48	61	37.4	33	20.2	0	0	69	42.3

Level of impaction

In maxilla and mandible level B impaction was more common 7.1% and 84.3% respectively (Table 7)

Table 7: Level of Impaction in Maxilla and Mandible

	MAXILLA		MANDIBLE	
	N	%	N	%
A	1	1	10	4.9
B	74	77.1	172	84.3
C	21	21.9	22	10.8

Discussion

Impacted third molar occurs frequently in patient and causes complications because of such natures it considered as a major problem in dentistry. Selection criteria included patients aged older than 19 years, as growth is essentiallycompleted by this age[10] and many third molars have their roots completed by this time.

In the present study it was revealed that the 36% of the maxillary third molar were impacted and 80% of the mandibular third molar teeth were impacted.

The mesioangular angle (42.8%) was the most common angle of impaction of third molar in the mandible which is in agreement with those of Quek et al [11], Kramer and Williams [12], Moris and Jerman [13] and Hemamalini Balaji et al [14].However, the findings are in contrastto those of Hugoson and Kugelberg [15], who found the verticalangulation to be the most common. The most common angulationregistered in the maxilla was the vertical angulation (58.8%) and this is inagreement with Quek et al [11]. However, it disagrees with Krugeret al[16] who found that mesioangular impaction was the mostfrequently observed pattern of impaction in the maxilla.

The B level was the most common level of impaction in both maxilla (77.1%) and mandible (84.3%) in this study. This agrees with the findings ofQuek et al [11] but not those of Hugoson and Kugelberg [15]. Many international studieshave been performed to identify the reason for third molar impaction. Several factors were reportedas possible causes for third molar impaction: including lack ofspace distal to the permanent second molar; retarded third molarmineralization; and early physical maturation[17-20].

It has been presented that a lower third molar may become impacted in three different ways: 1) It can follow the pattern of a normally developing third molar by decreasing its angulation to the mandibular plane and becoming more upright, but the up righting may not be sufficient to permit eruption; 2) its angular developmental position relative to the mandibular plane may remain unchanged; and 3) it can increase its angulation to the mandibular plane and become more mesially inclined.

The most common treatment for the impacted tooth was extraction and the reason for their extraction was because of impaction and its potential complications damaging the adjacent teeth or the involved tooth itself [21].A treatment controversy exists about the necessity and timing of the removal of asymptomatic, disease-free impacted wisdom teeth. Proponents of early extraction cite the cumulative risk for extraction over time and costs of monitoring to

retain wisdom teeth. Advocates for retaining wisdom teeth cite the risk and costs of unnecessary operations [22].

Abstract

Introduction: The saliva plays important roles in the maintenance of the oral health because it can prevent bacterial invasion, growth and metabolism through different mechanisms . Also, it can modulate the bacterial adhesion to teeth and attenuate the deleterious effects of the production of metabolites by oral microbiota due to its organic and inorganic components, contributing for oral health maintenance .The aim of this research is to evaluate the salivary pH,buffering capacity and flow rate levels of saliva in caries free people and in people with dental caries among different age groups .

Materials and Methods: The saliva samples of 120 children were collected with the aid of micropipette with disposable tips and plastic cylindersfor5 minutes. Salivary flow was determined by dividing the volume collected by the time of aspiration. All saliva produced was stored into a sterile plastic cylinder .The measurement of pH was performed with the aid of a digital pH meter and buffering capacity of saliva was measured.

Results: There was a significant decrease in the mean salivary flow rate, salivary pH and salivary buffer capacityinpeople with dental caries compared to caries free people among different age groups, P-value is statistically significant (p value - <0.05) in case of salivary pH and buffering capacity , whereas it is not significant in case of salivary flow rate (p value - >0.04).

Conclusion : The physicochemical properties of saliva, such as salivary flow rate, pH, buffering capacity and viscosity, has a relation with caries activity in people and act as markers of caries activity.

Keywords: *Buffering capacity,saliva,pH,flowrate,samples.*

Introduction

Saliva, a heterogeneous fluid comprising proteins, glycoproteins, electrolytes, small organic molecules and compounds transported from the blood, constantly bathes the teeth and oral mucosa. Whole saliva represents a mixture of the secretions of the major (submandibular, sublingual, parotid) and minor (accessory) salivary glands, together with the gingival fluid[1].Saliva is essential for the maintenance of oral health and it is an important diagnostic biofluid[1].It plays a pivotal role in protection and lubrication of oral mucosal tissues, remineralization of teeth, and alimentation[2,3].The composition of saliva gives it many important physical and biochemical properties[3].It is useful for diagnosis, prognosis, and management of patients with oral and systemic diseases[3].There is increasing inclination toward using saliva samples for the diagnosis of oral and systemic diseases[4].

Among the oral diseases, dental caries is the most common chronic disease of mankind[1,2].It is the main oral health problem in industrialized countries[3].Saliva definitely promotes oral health and hence lack of its secretion contributes to the disease process. The saliva which constantly moisturise the teeth and oral mucosa, functions as a cleansing solution, a lubricant, a buffer and an ion reservoir of calcium and phosphate, which are essential for the remineralization of initial carious lesions[1,2].A basal unstimulated secretion is produced continuously to moisturize and lubricate the oral tissues for more than 90 percent of the day[2,4].The normal resting salivary flow rate ranges from 0.25 to 0.35 milliliter per minute. Mechanical, gustatory, olfactory or pharmacological stimuli increase the production and secretion of saliva. Stimulated saliva represents 80 to 90 percent of daily salivary production, and the stimulated flow rate varies from 1 to 3 mL/minute[3].The salivary pH and the salivary buffering capacity are determined by the hydrogen bicarbonate balance in saliva. Salivary pH is approximately neutral, and buffering agents, such as inorganic phosphate in resting saliva and carbonic acid-bicarbonate system in stimulated saliva, help maintain neutrality[4].

Among the various protective functions of saliva, including diluting and cleaning the oral cavity, serving as a host defense, and buffering and enabling ion exchange, certain salivary characteristics outside the normal range of values may contribute to the caries process[4].Dental caries results from the dissolution of minerals from the tooth surface by organic acids formed from the bacterial fermentation of sugars.

Saliva maintains the integrity of oral hard and soft tissues and protects against immunologic bacterial, fungal and viral infections[5].Saliva controls the equilibrium between demineralization and remineralization in a cariogenic environment. Salivary buffers can reverse the low pH in plaque

and allow for oral clearance thus preventing demineralization of enamel. The flow rate and viscosity of saliva may also influence the development of caries[5].

The purpose of this study was to evaluate the relationship between the physiochemical properties of saliva such as flow rate, pH, buffering capacity in caries-free people and in people with dental caries among different age groups .

Materials andMethods

The study population consisted of 120 healthy children aged 7–15 years that was further divided into two groups:Group 1(7–10)years caries free and active children ,Group 2 (11–15) years caries free and active children. Unstimulated saliva samples were collected from all groups. Flow rates were determined, and samples analyzed for pH, buffer capacity.

Inclusion criteria :(1) children should be free from systemic or local diseases that affect salivary gland secretions (such as submandibular duct canaliculi, asthma and diabetes) and (2) children should be consuming only municipal water (those consuming hard water were not included as hard water consumption predisposes to dental fluorosis).

Exclusion criteria were on any medication for current and past illness and oral status other than dental caries like ulcers, oral tumors, herpetic lesions. Prior consent was obtained from the respective school authorities and from the parents through the school to conduct the study. The examinations were carried out in the subjects own surroundings that is, the school. The examination for dental caries was made according to the dentition status, and treatment.

Salivary Analysis

Collection of Saliva and Estimationof Salivary Flow Rate

Twelve milliliters of stimulatedwhole saliva was collected for the study.Salivawas stimulated by making the children to chew the paraffin wax for about 1 minute before spitting the saliva and the sample collection was carried out in the day time between 10 am and 12 pm, 2 h after breakfast. Then, the children were made to sit comfortably in a ventilated and well-illuminated room, and were instructed to spit the saliva, which was collected for exactly 5 min in a pre-weighed graduated cylinder. A note was made of this value. Saliva [redacted] collection was then continued till [redacted] [redacted] 12 mL of saliva was accumulated in the cylinder.Salivaryflow rate was calculated in gms/ml which is almost equivalent to ml/min.

Figure1: Collectionof Salivary Samples from the Subjects

Figure 2: Collection of Salivary Samplesin Plastic Cylinders

Estimation of pH and Buffering Capacity

• pH of saliva was measured by using digital pH me-ter.

• Buffering capacity of saliva {by Ericsson method 1959}:-0.5 ml of saliva was added to 1.5 ml of 5mmol/l HCl. The mixture was vigorously shaken and then centrifuged for one minute and allowed to stand for 10 min when the final pH of supernatant was measured by using manual pH meter (6)

Figure 3: Estimation of Salivary pHFig4:BufferingCapacity Analysis

Statistical Analysis

Statistical analysis of the data was performed with Student's t-test. Differences with P-values were considered to benot statistically significant.

Results

Salivary Flow Rate

Group 1

The mean level of flow rate in Group 1 Caries Free children is (3.61 +/- 0.58) , the mean level of flowrate in Group 1 Caries Active children is (3.22+/-0.23)therefore , p- value for group 1 is 0.4433 , which is not Statistically significant (p value > 0.04) by the rule of one – tailed hypothesis.

Group 2

The mean level of flow rate in Group 2Caries free children is (3.45+/- 0.2) and the mean level flow rate in Group 2 Caries active children is (3.25+/0.3)The mean level of flow rate is decreased in caries active children when compared to caries free children ,therefore the p – value is 0.467, it is not statisticallysignificant (p value >0.04) by the rule of one – tailed hypothesis. (Table-1)

Salivary pH

Group 1

The mean level of pH in Group 1 Caries Free children is (7.6+/0.94) , the mean level of pH in Group 1 Caries active children is (6.24+/-0.13),asthe p value is 0.000112 , therefore it is statistically significant (p value - <0.05) by the rule of one tailed hypothesis.

Group 2

The mean level of pH in Group 2 Caries free children is(7.13+/-0.13)and the pH in group 2 caries active children is (5.4+/-0.32)The mean level of pH is decreased in caries active children when compared to caries free children as the p value is 0.000306, and it is statistically significant(p value <0.05)by one tailed hypothesis .(Table-2)

Salivary Buffering Capacity

Group 1

The mean level of Buffering capacity inGroup 1 Caries Free children is (5.9+/0.53), and the mean level of buffering capacity in Group 1 Caries active children is (2.7+/-0.33), as the p - value is 0.006491, p value is statistically significant (p value <0.05)by one tailed hypothesis.

Group 2

The mean level of Buffering capacity in Group 2 Caries free children is (5.13+/-0.15) and the buffering capacity in Group 2 individuals is (3.5+/-0.21). Therefore the mean level of buffering

capacity is decreased in caries active children when com-pared to caries free children , p value is 0.004283,and it is statistically significant (p value <0.05) by one tailed hypothesis . (Table-3)

On observation from the below graphs : Series 1 represents the caries active children and series 2 represents caries free children .Graph 1 indicates salivary pHdecreased in caries active children when compared with caries free children which represents Table -3 , Graph 2 indicates salivary flow rate slightly decreased in caries active children when compared with caries free children which represents Table -1, Graph -3 indicates salivary buffering capacity decreased in caries active children when compared with caries free children which represents Table -2 .

Table 1: Shows the Salivary Flow Rate of Group 1 and Group 2 Caries Free and Caries Active Children

Groups				
Salivary flow rate	Mean	SD	T -value	P value
Dental caries free individuals				
Group 1 - age group (7-10 years)	3.61	0.58	1.432	(> 0.04)
Group 2 -age group (11- 15 years)	3.45	0.2	1.35	(>0.04)
Dental caries active children				
Group 1 - age group (7-10 years)	3.22	0.23	1.23	(>0.04)
Group 2 -age group (11- 15 years)	3.25	0.3	1.25	(>0.04

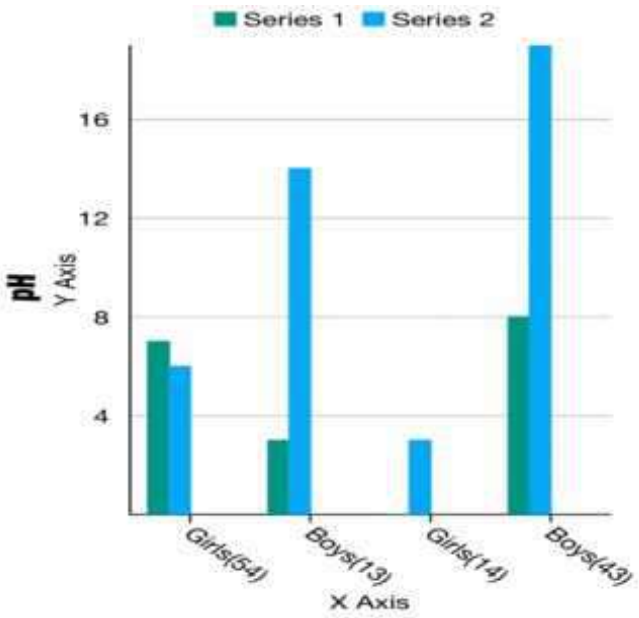
Table 2: Shows the Salivary pH of Group 1 and Group 2 Caries Free and Caries

Groups				
Salivary Buffering capacity	Mean	SD	T -value	P value
Dental caries free individuals				
Group 1 - age group (7-10 years)	5.9	0.53	2.44	(<0.05)
Group 2 -age group (11- 15 years)	5.13	0.15	2.3	(<0.05)
Dental caries active children				
Group 1 - age group (7-10 years)	2.7	0.33	0.8	(<0.05)
Group 2 -age group (11- 15 years)	3.5	0.21	1.43	(<0.05)

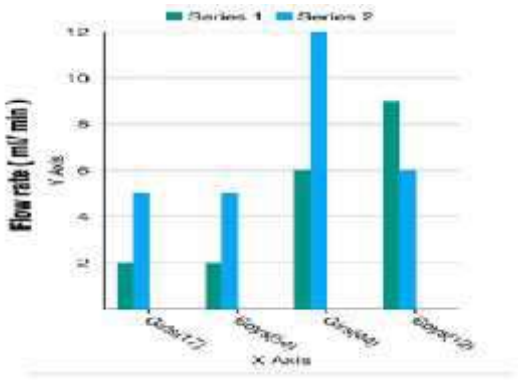
ActiveChildren

Table 3: Shows the Salivary Buffering Capacity of Group 1 and Group 2 Caries Free and Caries Active Children

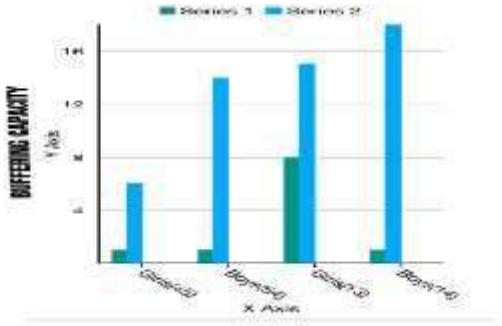
Groups				
Salivary pH	**Mean**	**SD**	**T -value**	**P value**
Dental caries free individuals				
Group 1 - age group (7-10 years)	7.6	0.94	3.55	(<0.05)
Group 2 -age group (11- 15 years)	7.13	0.13	3.45	(<0.05)
Dental caries active children				
Group 1 - age group (7-10 years)	6.24	0.13	2.54	(<0.05)
Group 2 -age group (11- 15 years)	5.4	0.32	1.97	(<0.05)



Graph 1: Shows the comparison of salivary pH between group 1 and group 2 caries active and caries Free Individuals



Graph 2: Shows the Comparison of SalivaryFlow Rate Between group 1 and group 2 Caries Active and Caries Free Individuals



Graph 3: Shows the comparison of salivary buffering capacity between group 1 and group 2 Caries Active and Caries Free Individuals

Discussion

Human saliva is an oral fluid that has several functions involved in oral health and homeostasis, with an active protective role in maintaining oral health[15].Saliva helps bolus formation by moistening food, protects the oral mucosa against mechanical damage and plays a role in the preliminary digestion of food through the presence of α-amylase and other enzymes. It also facilitates taste perception and also has a role in maintaining teeth enamel mineralization[14].

Dental caries has been thought of as a multifactorial disease as it is not only influenced by dietary factors but host factors as well documented[13].These defense systems include clearance, buffering, antimicrobial agents and calcium and phosphate delivery for remineralization, to name a few[12].The interaction of protective and pathologic factors in saliva and plaque biofilm, as well as the balance between the cariogenic and non-cariogenic microbial populations that reside in saliva,

decides the caries process[10].The factors in saliva most frequently related to dental caries are: (a) aciduric/acidogenic bacteria and (b) rate of acid production in the presence of glucose. Other factors that have been suggested as being related to dental caries include (a) amount of saliva secreted in a given time and (b) acid-neutralizing ability (buffering capacity) of saliva[14].

SalivarypH

In the present study , there was a significant difference in the mean salivary pH among the study groups Group 1 and Group 2 in both the caries free and caries active children and it is Statistically significant (p value < 0.05) . The results obtained are in accordance with the studies performed by Prabhakar in 2009[5] and Preethiin 2010[1].However, the results obtained in their studies were not significant. The salivary pH was only slightly reduced in caries-active children compared with caries-free children. Another study by Zhou in 2007[9]showed that the pH of saliva from early childhood caries children was statistically higher than that in caries-free children. In contrast, a study carried out by Thaweboonin 2008[8].revealed that the mean values for salivary pH were similar in caries-free and rampant-caries children. Swerdlove in 2013[3]andMalekipourin 2008[8].reported no relationship between the incidence of dental caries and the pH of normal resting saliva. Lambertsin 2005[12]observed no relationship of salivary pH rise activity and caries experience in caries-free and caries-active subjects[13].

Salivary Buffering Capacity

In the present study , there was a significant difference in the mean salivary buffering capacity among the study groups Group 1 and Group 2 in both the caries free and caries active children (p value <0.05) and it is Statistically significant (p value <0.05).The studies performed by Prabhakar in 2009[5]and Preethi in 2010[1]; Group I had a significantly higher mean salivary buffering capacity than that of Groups II and III. However, no significant difference was seen between the mean salivary buffering capacities of Group II and Group III. However, the results obtained in their studies were not significant[5].The salivary buffering capacity was only slightly reduced in caries-active children compared with caries-free children. Another study by Zhou in 2007[9]showed that the buffering capacity of saliva from early childhood caries children was statistically higher than that in caries-free children. A study performed by Malekipourin 2008[4]showed similar results, although the difference was not statistically significant[15].

Salivary Flow Rate

In the present study , there was only a small amount of significant difference in the mean salivary flow rate among the study groups Group 1 and Group 2 in both the caries free and caries active children (p value > 0.04) and it is not Statistically significant . Whereas, in the similar study of Lopez in 2003[2]therewas a significant difference in the mean salivary flow rate among the study groups ($P < 0.0001$). Group I had a significantly higher mean salivary flow rate than that of Groups II and III. Similarly, Group II had a significantly higher mean salivary flow rate than Group III[5].reported a salivary flow rate of 0.27 ± 0.14 in a group of children aged 5-12 years. The results obtained are in accordance with the studies carried out by Preethi in 2010[1]andPrabhakar in 2009[5]results obtained in their studies were not statistically significant. The salivary flow rate was only slightly reduced in caries-active children compared with caries-free people[18]. In contrast, a study performed by Thaweboon in 2008[8] revealed that the mean values for salivary flow rate were similar in caries-free and caries active people. The salivary flow rate did not influence the presence of caries[20].

Conclusion

Dental caries is a complex and dynamic process where a multitude of factors influence and initiate the progression of disease. One of the most important factor which influences the development of dental caries is saliva. Alterations in the physicochemical properties of saliva such as decreased salivary pH, buffering capacity play a major role in the development of caries, whereas salivary flow rate contribute only a small role in caries development. These results re-emphasize that there is a relationship of the various physiochemical properties of saliva, such as salivary flow rate, pH and buffering capacity along with the caries activity in the oral cavity.

Abstract

Introduction: The restoration of lost teeth is usually desired for two primary reasons – esthetics and to restore the function. The material used to restore the function must also be esthetically appealing. In recent years, flowable resins with lower filler content have been developed. Flowable resins have a composition similar to conventional resins with decreased viscosity due to lower filler content. Oral cavity is a challenging environment, which is exposed to fluids of varying pH and thus exposing the composite restoration to the challenging atmosphere.The aim of the study is to evaluate the surface morphological changes of flowable composite resins when exposed to acidic juices.

Materials and Method: Forty discs (7mmX2mm) of 2 different brands of flowable composites (NanoceramBrightFlow and Tetric N-ceram) of uniform shade A2 were prepared. Discs were immersed in distilled water for 24 hours for hydration. The specimens from each category were randomly divided into 4groups – group 1 lime juice, group 2 orange juice, group 3 coke and group 4 distilled water. The baseline values of the specimens were recorded using a colorimeter and then immersed in the respective experimental fluids. Values were recorded after 7 days and 14 days after immersion.

Result: Out of the two composites used, Tetric N-ceram showed more resistance to surface erosion by acidic juices. Of the three experimental acidic fluids, lime showed higher surface erosion in both the categories. The minimum surface erosion of composite among the different experimental fluids was seen in distilled water followed by coke.

Conclusion: The present study concludes that, frequent exposure to acidic juices should be avoided to reduce the risk of surface erosion of the flowable composites.

Key Words: *surface erosion, acidic juices, and resin composite.*

Introduction

Composite resin restorations came into existence into dentistry since 1990s and have evolved to a greater extent till now. Based on consistency, composite resins can be broadly classified into packable and flowable composite resins. Flowable composite resins have a similar composition to conventional resins except for the filler load which has been reduced to 37%-53%[1]. This filler load modifies the viscosity of the flowable resin composite[2]. Most of the manufacturers pack the flowable resin composite in syringes for easy dispensing with small gauge needles. This also makes them ideal for use in small preparations [3,4]. Acid erosion, also known as dental erosion, is a type of tooth wear and it is defined as the irreversible loss of tooth structure due to chemical dissolution by acids not of bacterial origin. Dental erosion is one of the most common chronic disease of children between the age group of 5-17yrs[5] though it is onlyrecently been recognized as a dental health problem [6]. There is a widespread ignorance of the damaging effects of acid erosion generally; this is specific in the case with erosion due to fruit juices, because they are tend to be seen as healthy[7]There has been considerable attention in recent times focused on the problems of tooth surface loss in both adults and children[8]. Dental erosion is one of the common conditions, which seems to be trending higher in recent decades[9]. In certain studies which have reported the prevalence of dental erosion in different age groups,states that there is a clear trend of increasing prevalence with age in children[10]. Acidic foods and drinks are the most common substance which causes dental erosion. In general, the pH level of food and drinks are below 5.0– 5.7 which have been known to trigger dental erosion effects[11]. Numerous

clinical and laboratory reports shows a link between erosion to excessive consumption of drinks. Additionally, wine has been shown to erode teeth, with the pH of wine as low as 3.0–3.8[12].

Indications of Flowable Resins

1) Class 1 restoration.
2) Cavity base or a liner for class II cavity.
3) Pit and fissure sealant.
4) Class V abfraction.
5) Bonding of orthodontic brackets.
6) Bonding of lingual orthodontic retainers.
7) Reattachment of fractured restorations.
8) Splinting fractured and mobile teeth.
9) Minimally invasive class III.
10Lutting porcelain and composite resin veneers[13].

Materials and Methods

Sample Preparation

40 small discs were prepared (7mmx2mm dimensions). Two different types of Nano hybrid flowable resin composites of A2 shade were used (group 1 – Nano ceram Bright Flow) (group 2 – Tetric N-ceram). The flowable resin composite was packed in a Teflon-mould and finger pressure was given with Mylar strip placed over it and polymerized with Light curing unit for 40seconds. The discs were finished with finishing bur of yellow grade and polished with shofu composite polishing kit in two sequences. Then the discs were immersed in distilled water for 24 hours to maintain hydration.

Experimental Fluids

Experimental fluids used in the study were lime juice, orange juice and coke. Lime juice and orange juice were diluted to a palatable state and their pH values were recorded using a pH meter (Table.1).

Experimental Groups

A baseline value was first recorded for all groups using a colorimeter, and then group 1 (Nano-ceram) and Group 2 (Tetric N-ceram) were divided into 4 subgroups and immersed into the distilled water, orange juice, lime juice and coke. After 7 days, the discs were taken out of the solution using tweezers and washed in distilled water; dried and the values were recorded. Disc were again immersed in to the respective solutions and recorded after 14 days and the values were measured.

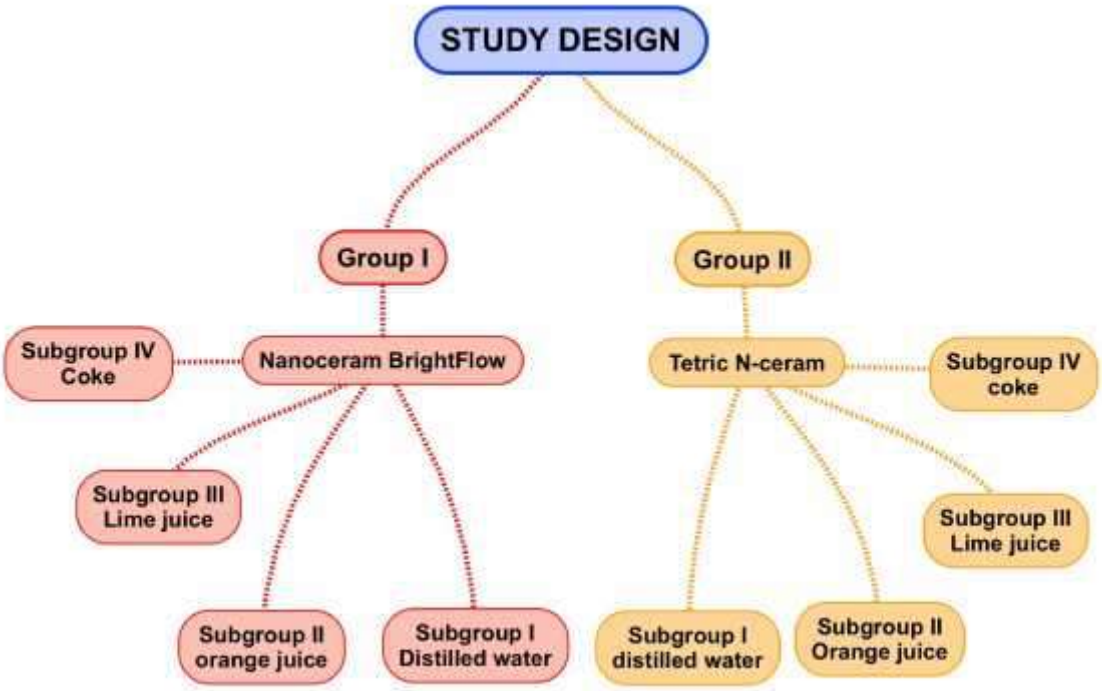

Figure 1: Flow chart depicting the study design

Result

The data were used to determine mean and standard deviation. The data was used to analyze with one-way ANOVA. From the statistical data, it was found that, there was no significant change in the values of day 7 when compared to control values, indicating that surface erosion has not taken place within the first 7 days. Specimens showed no significant change to coke in all the groups at all the days. But there were some significant changes in values, when compared with distilled water, which showed the least change.

The group that showed the highest susceptibility to surface erosion was group 2 Tetric N-flow. It showed surface erosion to lime juice on all days, which is high when compared to orange juice and coke. In group 1 Nano-ceram, orange juice and lime juice showed slightly more erosion when compared to coke. The experimental fluid that showed least surface erosion in both the group is coke. When comparing Tetric en flow and Nano Ceram for both after one week and after two weeks there was no significant p value.

Table.1: pH of the experimental fluids

EXPERIMENTAL FLUIDS	pH
Subgroup 1 (water)	7
Subgroup 2	3.4
Subgroup 3	3.6
Subgroup 4	2.53

Table-2: Mean and standard deviation of surface erosion of Tetric en flow and Nano Ceram for after one week and after two weeks observation.

TETRIC EN FLOW	SUBGROUPS	NO. OF SAMPLE (N)	MEAN	STD.DEVIATION

Discussion

Oral cavity is the challenging environment, which is exposed to fluids of varying pH. Many soft drinks are acidic and the pH is 3.0 or lower. This means that drinking acidic drinks over a long period and with continuous sipping can erode the tooth enamel and the resin material as well[15]. Flowable composite resins have similar composition to conventional resins except in filler content. When flowable composites are exposed to fluids of varying pH for a prolonged period, there is a chance of surface erosion of flowable composites. Surface erosion can lead to discoloration, secondary caries, leakageand plaqueaccumulation[16].

The studyconducted by Lee (1994) shows that fillers tend to fall out from resin materials, and the matrix component decomposes when exposed to low pH environments.[17,18]

Wongkhantee (2005) conducted a study to observe the behavior of varies composite restoration material when exposed to many foods and drinks (e.g., Cola soft drink, drinking yogurt, orange juice, sports drink, Tom-yum soup) that affects the behavior of restorative materials. The result showed that Cola soft drink significantly reduced surface hardness of enamel, dentine and composite surface. Orange juice and sports drink significantly reduced surface hardness of enamel and drinking yogurt and Tom-yum soup did not reduce surface hardness. This invitro study confirms the erosive potential of certain acidic food and drinks that public should be aware of. [19] When comparing the present study with this study, cola showed no drastic change in the surface erosion of composite even after two weeks in the present study.

Linlin HAN (2008) performed a study to evaluate the morphological changes of surfaces of flowable resins eroded by acidic juices like orange juice, wine and whisky. The result

showed similar surface roughness in the specimens eroded with orange juice and wine. Among all the experimental fluids- orange juice, wine and whisky, orange juice and wine showed higher surface roughness. The author concluded that one cause was the fall out of fillers which is due to insufficient surface treatment of fillers with silane[20].

Campbell reported a linear relationship between the optical scattering coefficient and the filler concentration. Chemical differences among the resin components, such as purity of the oligomers and monomers and concentration/type of activators, initiators, inhibitors, oxidation of unreacted carbon – carbon double bonds and fillers may affect the color stability as well[21].

Majewski (2001), had stated regarding the site of erosion, the prevalence on the buccal surfaces was higher – the reason for this is unclear. The Soft drinks have many potential health problems, including dental caries and enamel erosion [22].

Bowen and Lawrence (2005),had stated that the most frequent source of the acids is soft drinks like cola. It is also indicated that the cariogenicity of cola is higher than that of milk andsucrose [23].

Edwards (1999); Owens (2007), compared caries and dental erosion. He stated that dental erosion seems to have much stronger relationship with soft drinks than dental caries. The erosive potential of drinks is mainly represented by their pH and the buffering capacity. Carbonated drinks had lower pH than fruit juices. The buffering capacities are in the following order: fruit juices>fruit-based carbonated drinks>non-fruit-based carbonated drinks [24]

Lussi (1995); Lippert(2004); Jensdottir(2005), stated that even the sports drinks have a stronger softening effect than fruit juices [25,26,27].

Hara and Zero (2006),had concluded that some of the supplements in the drink, such as calcium, could reduce the progress of enamel demineralization [28].

Conclusion

In the era of esthetic dentistry, flowable composites form an in-homogenous group of materials. They exhibit a wide variety in their composition and consequently a variety of mechanical and physical properties. According to this research study, frequent exposure to acidic juices should be avoided to reduce the risk of surface erosion of the flowable composites. They are used in a wide variety of clinical situations and are subjected to various challenges in the oral cavity.

Abstract

Introduction: Saliva, a multi constituent oral fluid, has high potential for surveillance of general health and disease. Approximately of 700ml of saliva secreted daily is contributed by submandibular gland accounts for about 60%, parotid gland for about 30%, sublingual gland for about 5% or less and 7% from minor salivary glands. Saliva has a normal pH range of 6.5 - 7.6, the average pH is 6.7. Saliva acts as buffering agent and maintains the pH of oral cavity and prevents from environmental factors that may disturb the oral pH that enhances growth of microorganisms. The aim of this study is to analyze the salivary pH and determine its correlation in habit associated malignant and premalignant conditions.

Material and Methods: The study is conducted to assess the salivary pH among habit associated premalignant and malignant patients with apparently healthy control group. Saliva samples will be collected from the subjects and pH will be analyzed using pH strips.

Result: There was pH changes in certain cases on study but on statistical analysis there was no significance between pH of any conditions

Conclusion: Sample sized result showed there was no significance between pH of any conditions considered.

Key Words: *Salivary pH, habit, oral submucous fibrosis, leukoplakia, cancer*.

Introduction

Cancers are the most common cause of death in adults. Oral cancer is a heterogeneous group of cancer arising from different parts of the oral cavity, with predisposing factors, prevalence, and treatment outcomes. According to statistics, in 2012 incidence of oral cancer in India is 53842 in males and 231631 in females [1]. In India and Southeast Asia, the chronic use of betel quid has been strongly associated an increased risk for oral cancer [2]. Oral cancers can be diagnosed with early manifestations. The premalignant conditions are very important to be diagnosed as it can prevent a patient to become a cancer patient. The most common premalignant conditions of oral cancers are oral submucous fibrosis, leukoplakia, erythroplakia, oral lichen planus, and etc. Leukoplakia is described as a white patch or plaque that cannot be characterized clinically or pathologically as any other disease [3]. Several studies have shown leukoplakia has more malignant transformation rates ranging from 8.9 to 17.5 percent [4].Oral submucous fibrosis is a chronic fibrosing disease with progressive and unrelenting clinical course that leads to mucosal stiffness and reduced mouth opening. The initial presentation of OSF is inflammation. Inflammation is followed by hypovascularity and fibrosis visible as blanching of the oral mucosa with a marble-like appearance. Blanching may be localized, diffuse, or reticular. In some cases, small vesicles may develop that rupture and form erosions [5]. The predisposing factors of these conditions are smoking, alcohol intake, arecanut chewing, smokeless tobacco chewing, and etc. The most common is arecanut in combination with tobacco. Major constituents of betel quid are arecoline from betel nuts and copper, which are responsible for fibroblast dysfunction and fibrosis. Saliva, a multi constituent oral fluid, has high potential for surveillance of general health and disease. It has a normal pH range of 6.5 - 7.6, the average pH is 6.7. Alteration in salivary pH has a significant impact on orodental health. The aim of this study is analyze the salivary pH and determine its correlation in habit associated malignant and premalignant conditions [6].

Materials and Methods

The study was conducted to assess pH among habit associated malignant and premalignant patients with apparently healthy control group.

Selection of Subjects

A total of 30 subjects were included in this study of which 5 were oral cancer patients , 5 were oral submucous fibrosis patients , 5 were leukoplakia patients associated with adverse habits such as areca nut chewing, smoking, tobacco and 15 subjects of matching age with no addictive habits was taken as healthy control group. Volunteers suffering from systemic illness, pregnant women were not included in the study.

Saliva Collection Method

The subject was requested to not to drink or eat or chew or perform oral hygiene 15 minutes before and during the study. Subjects were made to sit in upright position and asked to spit on eppendorf container gradually. The subjects were instructed not to swallow during collection of saliva. After collection of saliva, the pH was measured. The salivary pH was measured immediately using pH strips. Manufacturer's instructions were followed while measuring salivary pH. The strip was dipped inside the collected saliva for approximately 10 seconds and color change was noted and compared with the standard chart given. The corresponding values was recorded and taken as the salivary pH.

Statistical Analysis

Data were entered and analyzed. The mean of the values of salivary pH was done with computerized software. The mean values of salivary pH of patients with carcinoma, oral submucous fibrosis, leukoplakia and normal control were compared.

Result

The results were used to determine mean and standard deviation. The data was used to analyze with one way ANOVA, t-test. From the statistical data, it is found, there is significant change in the values of pH in all conditions when compared to control group. Carcinoma group possessed highest pH changes when compared to OSMF and leukoplakia. Though Carcinoma is the condition in which highest pH change was noted there was no significance according to statistics whereas there was significant difference in case of OSMF and leukoplakia condition. On ANOVA one way test pH values of carcinoma, OSMF, leukoplakia conditions were compared and there was no significance

between any conditions. The insignificant differences may be as a result of limited sample size.

Table 1: T- Test

GROUP	*N*	*MEAN (pH)*	*SD (pH)*	*df*	*P-value*

Discussion

This study was done to analyze the salivary pH and determine its correlation in habit associated malignant and premalignant conditions. The A total of 30 subjects were included in this study of which 5 were oral cancer patients , 5 were oral submucous fibrosis patients , 5 were leukoplakia patients associated with adverse habits such as areca nut chewing, smoking, tobacco and 15 subjects of matching age with no addictive habits was taken as healthy control group. Saliva samples were collected in eppendorf container and pH was checked using pH paper strips. The results were noted and statistically analyzed. The data was used to analyze with one way ANOVA, t-test. From the statistical data, it is found, there is significant change in the values of pH in all conditions when compared to control group. Carcinoma group possessed highest pH changes when compared to OSMF and leukoplakia. Though Carcinoma is the condition in which highest pH change was noted there was no significance according to statistics whereas there was significant difference in case of OSMF and leukoplakia condition. On ANOVA one way test pH values of carcinoma, OSMF, leukoplakia conditions were compared and there was no significance between any conditions. The insignificant differences may be as a result of limited sample size. Saliva is an excellent diagnostic mark for precancerous and cancerous conditions, this has been proved in several studies done. The saliva contains several biomarkers that are used for diagnostic purposes. Similar study done based on pH changes in patients with oral submucous fibrosis showed that there was significant change in pH in patients with oral submucous fibrosis who were associated with arecanut chewing. In that study the salivary pH recovery time was statistically significant with average of 15.37 min longer than that of controls[6]. Various studies has been done for detection of precancerous and cancerous conditions using salivary contents. A study was done to based on salivary sialic acid, total protein and total sugar in oral cancer condition. The study showed that there was significant rise in sialic acid, total protein and total sugar in oral cancer condition particularly in well differentiated squamous cell carcinoma[7]. A study done by shen et al in detection of oral squamous cell carcinoma using salivary proteomics showed that the several salivary proteins were revealed on Subtractive proteomics differential levels between the oral squamous cell carcinoma patients. The combination of these biomarkers yielded an operating characteristic value of 93%, specificity of 83% and sensitivity of 90%

in detecting oral squamous cell carcinoma[8]. The early detection of precancerous lesions or conditions helps in prevention of oral cancer and its associated morbidity and mortality[9]. The gold standard method for early detection of oral precancerous and cancerous condition is biopsy[10]. But biopsy is a invasive procedure thus many research has been made to bring out best non invasive method that provides results that are obtained from biopsy. Such non invasive methods that has been found and yet to be found. Such methods are salivary diagnostics, toluidine blue dye or tolonium chloride, oral CDx brush biopsy kits, and optical imaging systems[11]. In salivary diagnostics, human salivary transcriptome is used in detection of cancerous condition, in which seven RNA complex were elevated in the saliva[12]. In a study, the serum and salivary TSA/TP ratios and α-l-fucosidase activity were measured in oral precancerous condition and oral cancer patients compared to the controls. The levels were significantly higher when compared to controls. The α-l-fucosidase activity and the Salivary TSA/TP ratio were elevated with higher magnitude than the serum levels[13]. In a study, salivary transferrin were used as biomarker for the detection of oral cancer[14]. In another study the presence of salivary interleukin 6, 8 and TNF alpha in oral cancer was studied. The study showed that the interleukin 6 were elevated and was statistically significant[15]. Similar study that was done for detecting salivary TNF alpha, interleukin 1,6,8 in malignant transformation of oral lichen planus, but the study showed there was no significance of the biomarkers[16]. Rhodus et al in their study showed that the TNF-α, IL-1α, IL-6, and IL-8 were found to be elevated in the whole unstimulated saliva of patients with oral squamous cell carcinoma which was compared patients with oral premalignant lesions and controls[17]. In a study, the analysis indicates that the five candidate markers M2BP, MRP14, CD59, catalase, and profilin collectively, provide a sensitivity of 90% and a specificity of 83% for OSCC detection[18]. Profilin 1 may be secreted into tumor microenvironments during the early progressive stage of tumor formation[19]. There are several studies for detection of oral premalignant and malignant conditions but very few are effective[20].

Conclusion

Saliva can be considered as first line diagnostic aid with advanced technology. Salivary pH does not remain constant and it differs for every individual. As per the study there was

significant change in salivary pH changes in all conditions but statistically it is not significant, it may be as a result of limited samples. Further studies on salivary pH changes in premalignant and malignant conditions with more sample size may show significance. Thus salivary pH changes then can be considered as a noninvasive diagnostic method of premalignant and malignant conditions.

Abstract

Introduction: Good hand hygiene is one of the most important actions healthcare workers can take to reduce the spread of infection and protect the lives of their patients.The main medical purpose of washing hands is to cleanse the pathogens and chemicals which can cause personal harm or disease. Hand-washing reduces the number of transient organisms on the skin surface.The purpose of the study is to find the effectiveness of educational intervention about hand washing techniques among dental students.

Materials and Method: This study is anPre-Post teststudy devoted to improve skills about hand hygiene. It was carried out among 50 dental students within a dental college, Chennai. We observed the hand-washing technique done by the student before training and instructed them with a proper hand washing technique and they were observed. Wilcoxon signed test was used to assess the difference in the hand washing steps in pre and post training.

Results: The results of the study showed that only 10% of participants were aware about proper six steps wheareas 90% were not aware about the proper six steps of handwashing technique before training. After giving an hands on training, all were aware about the proper six steps of hand washing technique. Hence, hand washing skill training was effective and this difference was found to be statistically significant.

Conclusion: It was found from the study that there was a significant improvement in hand hygiene techniques after an educational intervention which helps to avoid the spread of nosocomial infection from the dental professionals to patients.

Key Word:*Hand washing ,Nosocomial infection, Attitude,Hygiene,Personal barriers.*

Introduction

Hand washing or hand hygiene is termed as a washing one's hands with or without the use of water or antiseptic liquid, or with the use of soap for the purpose of removing dirt, and/or microorganisms[1].Studies done by IgnazSemmelweis in the 19th century, first recognized the role of the practitioner's hand in the transmission of infections in his article on the etiology and concept of childbed fever which later became awareness on maintaining hand hygiene practices during clinical procedures or attending on every single patient for examination[2]. "My five moments for hand hygiene"wasdevelopedby World Health Organization in 2009. These five protocols that plea for the practice of hand hygiene which are incorporated as anotebefore touching a patient, before performing aseptic and clean procedures, after being at risk of exposure to body fluids, after touching a patient, and after touching patient surroundings. This concept of hand washing has been timely used to enhance better understanding, training, monitoring, and reporting hand hygiene among dental professionals [3].Selfprotectionbarriers have to be followed by every dental Health Care Professional as a step towards cross infection control. These measures include immunization, hand wash and personal barriers[4].Disease transmission between healthcare professionals and patients is generally considered to occur first, through which many exogenously acquired nosocomial infections can spread by inter- and intra-hospital facilities[5]. Dentist particularlyare at an increasingly prone to infections as they provide care working with sharp instruments at very high speeds and limited access in an environment that is bathed in saliva and, in many instances, blood[6]. Hands of dental students get progressively colonized with different microbial flora either commensal or potential pathogens during routine patient care. It has been learnt that bacterial count increases linearly over time[7]. Hand hygiene is an important healthcare controversy globally and is a single most cheap and efficiently measure to cut down the extent of nosocomialinfection and the spread of antimicrobial resistance across all hospitality surroundings right from advanced health care systems to primary healthcare centers[8,9] It is considered to be an simple , cheap and most effective means of controlling cross infections. Hand hygiene methods is designed to save lives and provide a safe treatment atmosphere for all patients and for health care professionals[10]. Hand washingtechnique is denotes in different terms are as hand antisepsis, disinfection, degerming, decontamination or sanitizing.Usage of various antimicrobial chemicals have been

incorporated into hand-washing agents such as chlorhexidine, iodophors, quaternary ammonium compounds, and alcohols[8]. As dental student become more involved in patient contact during their training, they are at risk of exposure to pathogens. It is the responsibility of academic institutions to facilitate appropriate preclinical immunization and provide training in infection control to protect patients and the health and careers of undergraduates, and to lay the foundation for safer work practices in health care[9].In this sense, hand hygiene is important preventive measure, working as the main action to reduce those infections and cross-transmission of said pathogens, especially the multi-resistant ones,including the oral healthcare setting[10].It is also to be a milestone of infectious disease control, and promotion of improved hand hygiene has been recognized as an important public health measure[11].

The reasons for poor hand-hygiene practices include lack of scientific knowledge, unawareness of risks, misconceptions (e.g., glove use obviates the need for hand hygiene), unavailability of hand-hygiene facilities (sinks or alcohol dispensers), lack of role models among colleagues or superiors, understaffing or patient overcrowding, andlack of institutional priority[12]. Similarfindingsreported that the main barriers to regular hand hygiene were lacked of adequate facilities, forgetful- ness and lack of time[13]. Major drawback for inappropriate hand washing among dental students which includes work overload, insufficient sinks, patients general condition, and inaccessibility of hand-washing agents[14]. The purpose of thestudy is to find the effectiveness of educational intervention about hand washing techniques among dental students.

Materials and Methods

A Pre-Post study design was used to find the effectiveness of educational intervention about hand washing techniques among 50 dental students in a dental college, Chennai. Students willing to participate were included in the study and those who did not attended health education intervention were excluded. Ethical clearance was obtained from the ethical committee of the institution. The intervention was done after observing their hand washing technique. Health education was given by demonstration and flip charts. It is included the proper six steps of hand washing and it’s necessity in maintaining personal hygiene and disease prevention. Six steps in hand washing technique are as follows

- Wet hands with water, apply enough soap to cover all hand surfaces. Rub hands palm to palm
- Right palm over left dorsum with interlaced fingers and vice versa.
- Palm to palm with fingers interlaced
- Fingers of one hand over the other with fingers interlocked
- Left thumb clasped over right thumb by rotational motion of rubbing and vice versa.
- Rotational rubbing backwards and forwards with clasped fingers of right hand in left palm and vice versa. Rinse hands with water and dry it.

Data was entered in SPSS software and statistical analysis was performed. The tests applied were : Wilcoxon signed tests and value is less than 0.01 were considered statistically significant.

Result

By observing the before and after hand washing technique, data was recorded and analyzed statistically. Majority of the dental students was not aware about all the steps in hand washing technique. Only 10% of participants were aware of six steps whereas 90% were not aware proper six steps of hand washing. Totally six steps were assessed before and after training of hand wash. It was found that there wasn't any difference before and after instructions in the step 1 hand washing technique among study participants. Before providing hands on training, it was found 88% of study participants were aware and 12% were not aware of step 2 in hand washing techniques. After hands on training, all the participants performed step 2 hand washing procedure correctly. This difference was found to be statistically not significant. In step 3, it was found 80% of study participants were aware whereas 20% were not aware of step 3 technique. After training all the participants performed step 3 procedure correctly, it shows statistically significant. Similarly before hand on training, it was found 58% and 70% of study participants were not aware of step 4 and step 5 respectively. After hand on training, all the participantsperformed step 4 and step 5 hand washing procedure correctly. This difference was found to be statistically significant.

Discussion

Hand hygiene prevents cross infection in hospitals, however adherence to guidelines is commonly poor[15]. Proper hand washing and use of barriers such as gloves, gowns, and mask are the main components of standard precautions which can minimize muco-cutaneous exposures[16].While the methods incorporated in hand hygiene are simple, the complex linkage of elements that determine hand hygiene behavior which makes us to study the hand hygiene complex [17]. In this study, students before hands on training had less knowledge about the steps of hand washing techniques and 90% of study participants were not aware about hand hygiene, later they were given training on hand washing technique in which nearly all the participants performed all six steps in hand washing techniques correctly. Study done by Chatterjee et al. shown that moderate knowledge of hand hygiene was reported among 76% of the total study population. Only 8% of participants had good knowledge and 16% showed poor knowledge with respect to hand hygiene practices[18]. In another study by Nair et al,among health care workers of a tertiary health care centre at Raichur, Karnataka, it was reported that the study participants had moderate knowledge on hand hygiene[19].Study done by Van de Mortel et al. [20] have shown that 63% of medical students were aware of the proper indications of hand hygiene while Mann and Wood [21] reported awareness in only 56% of students. In a study done byKadi et.al, it was found that compliance with hand hygiene among medical students was only 17% as compared to the level of awareness (56%) among the same group of students[22]. Factors which are affecting the compliance of hand hygiene are lack of time, forgetfulness, lack of knowledge

of importance of hand hygiene in preventing cross infection, less access to hand washing resource, work overload and cause skin irritation to hand hygiene products. A study done by Abhinav Singh et.al, among dental students of central India, in which students had shown a poor response to knowledge based questions and the authors had stressed on the need for more education programs for infection control as mandatory along with Hepatitis B immunisation measures[23]. In contrast, study done by Glad Mohesh and AbinayaDandapani, the difference between knowledge and attitude had been much lesser compared to the actual practice of hand hygiene[24]. It depicts the real ground level situation where budding dental students have moderate understanding of good hygiene practices. This moderate information may turn out as poor practices during their professional course. The level of knowledge about the hand hygiene compliancewas poor among the students. Attributable reasons could be inadequate training for infection control measures, inadequate supply of personal protective equipment, and carelessness[6]. Ansari et al. had conducted a study to evaluate the effect of hand hygiene practices on patient's health and cost where before and after evaluation of hand hygiene practices among doctors and nurses from a tertiary health centre, was done. It was reported thatdrastic and significant improvement in the right technique and significance of hand hygiene (7.1% to 46.4% among doctors and 2.2% to 45.5% among nurses) knowledge was observed after a health education programme[25].

In the present study dental students were given hands on training to gain knowledge on how to wash handsand there was significant difference in each steps of hand washing procedure in before and after educational training. A study done by Mobashr KA and Ibrahim MA reported that most of the medical students performed hand hygiene and data showed that the overall average of medical student’s knowledge about nosocomial infection was 68.34%[26]. Ayub A et al. showed in their study, only 31.25% medical students always followed hand hygiene procedure and also complete knowledge about hygiene and infection control procedures was present among 77.5% of students[27].Standard techniques of hand washing were always found to be efficient in removing transient contamination on hands and the present study was designed to create an awareness about the knowledge on hand hygiene and its importance. The observed hand washing behaviors and the length of time washing hands relate differently to different factors and so we need to create awareness on handwashing to prevent from infections.

Conclusion

It was found from the study that there was a significant improvement in hand hygiene techniques after an educational intervention. We need to create awareness on hand hygiene and to be practiced in order to reduce nosocomial infections and other microbial infections.Compliance programs on hand washing technique should be developed early in training and more frequently in the graduation and professional courses for dental healthcare personnel. The review of guidelines on hand hygiene, however, should be improved both for practices and standardization to help the projection of successful strategies for the intervention.

Abstract

Introduction: Dental caries is a major health problem. Many bacteria are involved in the process of developing dental caries whereby *Streptococcus Mutans are*one of the predominant bacteria that initiate the formation of dental caries. Indian medicinal plants are known to have many important secondary metabolites such as alkaloids, flavonoids, tannins, phenolic compounds which impart the antimicrobial properties. This study is aimed to determine the antimicrobial activity of Cinnamon oil, Rose Mary oil and Tea Tree oil against *Streptococcus Mutans.* To evaluate the antibacterial activity of the three essential oils against the selected bacterial pathogen

Material and Method: The antibacterial activity is carried out by *agar well* diffusion technique against the bacterial pathogen and the zone of inhibition is measured in mm diameter.

Result: In the present study, usage of these three oils was found to be equally effective against the microbe tested compared with the control.The maximum zone of inhibition was seen with Cinnamon oil measuring 26mm diameter followed by Tea tree oil and Rosemary oil

Conclusion: The result of this study reveals that essential oils exhibit antimicrobial propertyagainst *Streptococcus*Mutans. Hence it can be concluded that essential oils like cinnamon oil, tea tree oil and rosemary oil have effective antimicrobial property and can be utilized against various infections caused by oral microbes.

Key Words: *Cinnamon oil, Rosemary oil, Tea tree oil, Agar well diffusion technique, zone of inhibition*

Introduction

Dental caries is caused by the metabolic results of specific microorganisms which are the outcome that leads to disintegration of inorganic parts of enamel, dentin, cementum and degradation of their natural structure. Numerous microorganisms are associated with the process of developing dental caries in which Streptococcus Mutans are one of the prevalent microscopic organisms that starts the development of dental caries. Streptococcus Mutans are viewed as the most cariogenic in every single oral streptococcus[1]. Streptococcus Mutans can colonize the surface of the tooth and create a lot of extra-cellular and intra-cellular polysaccharides.[2]This microorganism in addition is very acidogenic and aciduric, and it uses a few salivary glycoproteins, subsequently overseeing the underlying phase of oral biofilm development and caries. Indian medicinal plants have been known to have numerous vital optional metabolites such as for an example, alkaloids, flavonoids, tannins, phenolic and antimicrobial properties. In the past, there has been an expanded enthusiasm for the helpful properties of some therapeutic plants and essential oils. [3]

Essential oils (EOs) are recognised for their identified antimicrobial action that goes against Streptococcus mutants. Their intricate unpredictable characteristic and mixed shape by fragrant plants are optional metabolites. They are known for their bactericidal, virucidal, fungicidal, calming, mitigating, pain relieving, spasmolytic, and local analgesic properties. The presence of complex chemical structures constitutes several groups such as terpenes and terpenoids, aromatic and aliphatic constituents, all characterized by low molecular weight, whereby explains their successful bacteriostatic and bactericidal action [4].

The aim of this studyis to assess the antibacterial activity of the three essential oils which is cinnamon oil, rosemary oil and tea tree oil against chosen bacterial pathogen

Cinnamon Oil

Cinnamon oil is the most volatile oil. Cinnamon is sweet zest savored over the world. It is additionally utilized as a home-grown tea. Cinnamon is also used to extricate an essential oil which has its correct sweet, pervading smell which is extremely mitigating. Cinnamon oil has numerous medical advantages [5].

The source of cinnamon oil is the sweet flavor from Cinnamomum verum. This is known as the true cinnamon. There is a less expensive assortment of cinnamon powder that we get from trees in the Cassia family. This modest cinnamon originates from China, while true cinnamon develops in numerous parts of the tropical world, notably in Sri Lanka and India. Although Cassia cinnamon is additionally used to extract the basic oil, the ones from the true cinnamon is the one which has great medical advantages. There are two sorts of essential oil obtain from this tree. First, is the Cinnamon leaf essential oil-the extract is steam refined from the leaves of cinnamon and it is yellowish in shade. Next is the, Cinnamon bark essential oil – the extract is steam refined from the bark of cinnamon and It is marginally rosy in shade with a trace of brown. [6].

Customary Uses of Cinnamon Oil

Cinnamon has been known as a standout among the most well-known flavors and seasoning. For an example, it has been utilized as a flavor in desserts and chewing gum due to the charming and invigorating impacts that it creates in the oral cavity. Therefore, it indicates useful impacts on oral wellbeing and is utilized for toothaches, oral diseases, and halitosis. [7] Cinnamon has additionally been utilized to treat skin inflammation and melisma. [8] In addition, cinnamon has also been utilized for the treatment of gastrointestinal and colonic diseases. [9] Cinnamon has coagulant impact and along these lines it can be utilized against discharging. [10] Cinnamon expands the blood stream in the uterus and enhances tissue recovery. [11] In addition, it has powerful antibacterial, antifungal, antiemetic, larvicidal, nematocidal and insecticidal properties. [12]Moreover , biological research has demonstrated that cinnamon has intense neuroprotective, hepatoprotective, cardioprotective and gastroprotective impacts due its powerful hostile to oxidant and calming properties. [13] Cinnamon oil can likewise be utilized as a part of fragrance-based treatment, which is helpful in utilization of plant base oil that can be consumed into the body by means of the skin or olfactory system.

Antibacterial Effects of Cinnamon Essential Oil and Cinnamon Extracts

One of the most well-established properties of cinnamon extricates, essential oil and their parts is the antibacterial movement against Gram Positive and Gram Negative microscopic organisms responsible for human irresistible maladies and debasement of sustenance or beauty care products. In the literature, there are number of studies demonstrating the

antibacterial action of cinnamon oil acquired from various herbal parts using extraction techniques.

In addition, cinnamon could be utilized to treat appealing malady. Nonetheless, there is an absence of clinical trials on the antibacterial impacts of cinnamon and its synthetic constituents, and in this manner its clinical adequacy isn't clear. Adding on, it is outstanding that cinnamon oil's poisonous quality is a standout among the vital issues, as some basic oils demonstrate the detailed negative impacts on human cells, for example, cytotoxicity and cell demise. Consequently, the use of common items in the treatment of appealing illnesses are possibly thought about in fascination rather than other options to engineer anti-toxins, particularly for the treatment of anti-infection safe bacterial diseases. [14]

Cinnamon oil has numerous restorative properties like Antibacterial whereby cinnamon oil is used in aromatherapy blends to get rid of airborne bacteria. It consequently avoids numerous respiratory tract contaminations. It has Antioxidant, Anthelminthic, Antiseptic, Immuno stimulant, Anti-incendiary, Analgesic, Expectorant, Antifungal, and Antidepressant and Hypoglycemic exercises. [15]

Rosemary Oil

Rosemary oil is derived from Rosmarinus officinalis (otherwise called Rosmarinus coronarium) hailing from the Labiatae family and is otherwise called incense. Rosemary oil has a unique, intense invigorating home grown smell; it is clear in shielding and watery in viscosity. The name was taken from the Latin word 'Rosmarinus' or 'ocean dew', as it is somehow attached to water. The Egyptians, Hebrews, Greeks and Romans thought about the herb as holy and even in the Middle Ages it was utilized to avoid indecencies spirits and also utilized as an assurance against torment. It was singed in French doctor's facilities amidst pestilences.

The principle compound segments of rosemary oil are a-pinene, borneol, b-pinene, camphor, boranyl acetic acid derivation, camphene, 1,8-cineole and limonene. [16]

Rosemary oil has been basically known for its relieving and calming impacts. While these have just been demonstrated as of late in a few studies, the true component by which rosemary applies this specific influence remains a secret. [17] Regardless, rosemary essential oil is known to have the additional wellbeing properties.

• Anti-provocative – decreases the diverse physiologic indications of incendiary procedures including expanded emission, swelling, agony, and delicacy

• Antimicrobial – can help execute certain microorganisms including gram negative and gram-positive microbes, oxygen consuming and anaerobic microscopic organisms, and certain types of growth

• Antioxidant – mitigates the impacts of oxidative weight on the body

• Antispasmodic – eases fitful conditions, for example, renal colic and dysmenorrhea

• Antitumorigenic – keeps the procedure and improvement of tumor cells and other neoplastic development

• Choleretic – invigorates the liver to deliver more bile in order to emulsify fat in the stomach related tract and enable it to be consumed and used appropriately

• CNS stimulant – fortifies the focal sensory system including incitement of the autonomic sensory system to make the individual feel more vivacious, have incredible state of mind, and better memory and other psychological procedures

• Hair producer – encourages the development of hair

• Hepato protective – secures the general propriety and physiologic work of the liver

• Mood enhancer – gives a superior feeling of prosperity

• Smooth muscle relaxant – enhances the general tonicity of the smooth muscles, especially those of the gastrointestinal tract and the respiratory tract. [18]

Uses

The principal use of rosemary today is in aromatherapy where it is often regarded for its ability to calm the senses while inducing an overall state of wellbeing. The following are the most common uses of rosemary oil.

• **Aromatherapy** – Either as a pure essential oil or as an addition to other essential oils, rosemary is extensively used in spas and health and fitness centers. It can induce a more

relaxed state, improve mood, and induce a state of wellness that can be an excellent way to manage one's stress.

• **Massage** – When used as an essential oil for massage therapy, rosemary can help relieve sore muscles while at the same time help facilitate the enhancement of blood flow. Consequently, this facilitates the more efficient elimination of toxic waste.

• **Management of Certain Infections** – Certain respiratory and digestive tract infections has been shown to be managed by the introduction of rosemary essential oil in the therapy. This is often used in combination with pragmatic antimicrobial therapies.

• **Alopecia** – There are plenty of rosemary products that are combined with other essential oils designed to help follicle-challenged individuals hair growth. When used in combination with aloe Vera extracts, rosemary oils can provide the benefit of an excellent hair cultivator and tonic.

• **Hepatotoxic Disorders** – Individuals who are addicted to drugs or have alcoholic problems or are taking hepato toxic medications, the consumption of rosemary oil supplements can help protect the liver by aiding in the different hepato metabolic processes.

• **Bronchial Asthma** – The anti-inflammatory property of rosemary oil can reduce the inflammation and the abnormal copious secretions in respiratory disorders. Rosemary is also known to reduce the spasms of the bronchial airways associated with asthma. This helps the individual to breathe a lot better.

• **Spasmogenic disorders** – Dysmenorrhea and renal colic are just two of the most common spasmogenic disorders. Rosemary can help reduce the spasms in these conditions to provide pain relief.

Other potential uses of rosemary oil include indigestion, gout, eczema, headache, and menstrual irregularities. [19]

Tea Tree Oil

Tea-tree oil, also known as melaleuca oil, is yellowish hued basic oil that is produced using the leaves of the plant Melaleuca alternifolia (local to Australia). Tea-tree oil and tea oil are totally unique items. Tea oil is the sweet flavorful cooking oil squeezed from Camellia sinensis (refreshment tea plant), or the tea oil plant Camellia oleifera. The topical use of tea-tree oil is known to have useful curative [20].

Tea Tree Oil Uses

Tea tree leaves were initially utilized for recuperating skin infirmities. Creepy crawly nibbles, skin spots, and cuts are treated by pounding the leaves and applying them to the territory required. Tea tree oil has likewise been utilized to regard conditions, such as, skin inflammation on athlete's foot, Dandruff, vaginitis, thrush, periodontal diseases, lice, dermatitis, Psoriasis, yeast contaminations, and as a general disinfectant. [21] It is frequently utilized as a part of creams, balms/cleansers, moisturizers, and shampoos. Not just Tea tree oil help with bad breath (halitosis), but since it has anti-microbial characteristics; it can likewise help mend gum diseases. It can treat serious gingivitis (gum malady/periodontal infection) and difficult gums. This is one of the fundamental reasons why a dental specialist would advise a patient to utilize toothpaste that contains Tea tree oil for treating awful breath. [22]

Material and Methods

Essential oils used are cinnamon oil, Rose Mary oil and tea tree oil.

Test organisms: The organism *Streptococcus Mutans* was isolated from saliva sample using special media [Mutants – sanguis agar] and maintained in Tryptose soya agar at 4-degree C in department of Microbiology, Saveetha dental college and hospitals.

Method

The Antimicrobial activity of the three essential oils was evaluated against *Streptococcus mutants* by agar well diffusion technique. [23] Both culture of the test organism was compared to Mac Farland's standard 0.5[24] which were set. Lawn culture of the test organism was made on the Muller Hinton agar [MHA-Hi media M-1084] plates using sterile cotton swab and the

plates were dried for 15 minutes. Wells measuring 4mm in depth was made on the agar using sterile cork borer. 100microlitres of the essential oils were added to the wells. 0.2% chlorhexidine was used as positive control. The plates were incubated at 37-degree Celsius overnight and the zone of inhibition of growth was measured in mm diameter. The entire test was done in triplicate to minimize the test error.

Results

In the experiment carried out, the antibacterial activity of Cinnamon oil, Rose Mary oil and tea tree oil were screened against Streptococcus Mutans using agar well diffusion test and the zone of inhibition was measured in mm diameter. The results are given in table 1. The area of inhibition where the growth of microorganisms was inhibited by the oils was observed to be significant against the pathogen used when compared with the control. The maximum zone of inhibition was seen with Cinnamon oil measuring 26mm diameter followed by Tree tea oil and Rosemary oil

Table 1: Antibacterial activity of three essential oils against *Streptococcus Mutans*

Essential oils	**Zone of inhibition (in mm diameter)**
Cinnamon oil	26
Rosemary oil	22
Tree tea oil	24
0.2% Chlorhexidine (control)	35

Discussion

Essential oils [EO] and different concentrates of plants have advance enthusiasm as sources of normal items with promising antimicrobial action. Essential oils are extracted from plant materials, for an example, bloomed buds, seeds, leaves, twig and so forth. EOs is a blend of

uneven constituents delivered by fragrant plants as auxiliary metabolites, as a defensive system against predators, microorganisms or climate misfortunes. The antimicrobial movement of essential oils is because of little Terpenoids and phenol compound present in it. Essential oils have been tried in vivo and in vitro antimicrobial action and a few has shown to be to having antimicrobial potential. Their system of activity gives an overwhelming impression on the cell layer by disturbing its structure in this manner causing cell spillage and cell passing, and optional activities perhaps hindering the film amalgamation and hindrance of cell breath. [23] They promptly enter the cell layer and apply their organic impact due to high instability and lipophilicity of essential oils. [25]

Usually ethanol is added to the essential oils as a solvent to enhance the volatility and aromatic properties. [26] To avoid the possible effect of solvent on the antimicrobial property, commercially available essential oils that were non-dilated and chemically not altered by any solvent or processing were used in this study. The Essential oil that was used in this study was the one commercially available in the local market. The three essential oils demonstrated in this study showed effective antibacterial activity against S.mutans, of which cinnamon oil was found to be the most effective. The antimicrobial activity of cinnamon oil is explained by its active substances which is cinnamon aldehyde and eugenol [27]. among the major component cinnamaldehyde exhibited the greater antibacterial activity against S.mutans. Therefore the essential oil of C.verum containing cinnamaldehyde showed the uppermost activity. Essential oils containing mainly aromatic phenols or aldehydes have been reported to exhibit considerable antimicrobial activity, whereas essential oil containing terpene ether, ketone or oxide has weaker activity. [28]

Antibacterial activity of cinnamon oil has been stated in studies conducted by Prabuseenivasan et al in Chennai in 2006,[8]Kalemba et al in 2006 in Poland[29] and Kamal RaiAneja et al in Haryana, India in 2009[30]. The essential oil of C.verum was not harmful when consumed in food additives and maybe used as an antibacterial agent. However, there are Occasional case reports of allergic contact dermatitis and stomatitis among consumers.

In the agar well diffusion examine, the size of effective inhibitory zone depends on the solubility and diffusion characteristics of the substance being tested. This makes the comparison of the different oils difficult. Therefor the results of this study may not directly reflect the extent of the antibacterial potential of these oils. However, as these effective zones were clearly visible, this is the proof of their antibacterial efficacy. Thus, as some these

essential oils have antimicrobial efficacy in contrast. In vitro, in vivo study containing this essential oil is recommended to allow these essential oils to be incorporated within formulation and marketed against oral infections.

Conclusion

Cinnamon oil, Rosemary oil and Tea tree oil exhibit antimicrobial property against S.mutans. Cinnamon oil showed highest activity against streptococcus mutants followed by Tea tree oil and Rosemary oil. Hence, this study concludes that the three essential oils has effective antimicrobial property and can be used to fight against various diseases, infection and other problems which are being caused by oral microbes.

Abstract

Introduction: The mental foramen is located in the apical region of the mandibular premolars but it has some variations regarding its distance to both premolars and the base border of mandible that may make a problem especially for the oral surgeon in his work. The aim of this study is to evaluate the variation of mental foramen in mandible according to sex and age using orthopantomogram (OPG).

Materials and Methods: The samples for this study are collected from 150 patients. The patients selected in this study ranges from 21 to 50 years old, divided into three groups, namely, 21 to 30, 31 to 40 and 41 to 50 and also divided according to gender. All radiographs are examined and then the position of the mental foramen for each patient is recorded.

Results: The results revealed that the distance between the mental foramen and the base border of the mandible changes with age and does not aid in determine the gender.

Conclusion: The position of mental foramen does not play a role determining the gender and has significance in determining the age.

Key Words: *Mental foramen, Inferior border of mandible, OPG, Age, Gender*

Introduction

Mental foramen is an important anatomical landmark to facilitate surgical, local anesthesia and other invasive procedures for dental surgeons performing peri apical surgery in the mental region of mandible. Its location and the possibility that an anterior loop of the mental nerve may be present mesial to the mental foramen, needs to be considered before any surgery in the foramina area in order to avoid any nerve damage. (1) The mental foramen is situated bilaterally on the antero lateral aspect of the mandible, down to the alveolar margin. The mental nerve and vessels emerges through the mental foramen and supply sensory innervation and blood supply to the soft tissues of the chin, lower lip and gingiva. (2) But the position of mental foramen vary among various age groups and gender. Mental foramen holds strategic importance in clinical dentistry and oral surgery. (3),(4) Its accurate identification determines the effectiveness of nerve block and prevention of post operative neurovascular complications in the mental region like neurosensory disturbances, paralysis, hemorrhage, altered sensation, orofacial pain, a typical neuralgia etc. Thus, the mental foramen is an important landmark in dentistry. The present radiographic study is aimed at evaluating how location of mental foramen varies according to age and gender in 150 patients.

Materials and Methods

Fifty patients with the age ranged 21 to 50 were selected for this study. The samples were divided into 3 equal groups regarding age as the following. First group: 21 to 30 years (45 patients), second group: 31 to 40 years (60 patients) and third group: 41 to 50 years (45 patients). Also the samples were divided into male and females following the age group. Fifty digital views were taken for the patients, using computerized digital panaromic X-ray machine. The orthopantomograms were examined for estimation of mental foramen for each patient. The distance between the mental foramen and inferior border of the base of mandible were measured. These measurements were done by using a digital ruler on the computer monitor. Readings were then taken and recorded and a conclusion was made.

Results

The results in table 1 show that the distance between the mental foramen and the inferior border of the mandible, for the first age group ranged between 2.87 and 0.27, with the mean value of 1.57. For the second age group ranged between 2.40 and 0.20, with the mean value of 1.3. Lastly, for the third age group ranged between 1.12 and 0.08, with the mean value of 0.6. The results in table 2 show that the distance between the mental foramen and the inferior border of mandible, for the male ranges from 1.67 to 1.82, and for the female it ranges from 1.65 to 1.79.

Table 1: Distance between the position of mental foramen and inferior border of base of mandible in OPG (in cm)

AGE GROUP	MAXIMUM	MINIMUM	MEAN VALUE
21-30	2.87	0.27	1.57
31-40	2.40	0.20	1.3
41-50	1.12	0.08	0.6

Table 2: Distance between the position of mental foramen and inferior border of base of mandible in OPG

GENDER	21 - 30		31 - 40		41 - 50	
MALE	MIN	1.48	MIN	1.47	MIN	1.45
	MAX	2.23	MAX	2.07	MAX	1.89
	AVERAGE	1.82	AVERAGE	1.79	AVERAGE	1.67
FEMALE	MIN	1.40	MIN	1.45	MIN	1.43
	MAX	2.18	MAX	2.09	MAX	1.87
	AVERAGE	1.79	AVERAGE	1.77	AVERAGE	1.65

Discussion

Age Changes in Mandible

After birth, the shape of the mandible is constantly modified. In neonates, the corpus of the mandible bilaterally holds the alveoli for deciduous incisors, the canine tooth and two molars. In this period the mandibular canal is relatively wide, because it holds the yet divided inferior alveolar nerve and vessels. It is placed near the lower edge of the mandibular corpus. This form of separate innervation of the canine tooth, premolar and molar areas exists only in the neonatal period. In the persistent form, this canal exists posteriorly to the mandibular foramen, as the canal of Serres, which holds the Serres vein. The mental foramen is located low and relatively far towards the posterior, below the first molar bud. The angle between the corpus and the ramus of the mandible is obtuse (150º–160º), and the condyloid process is small. However, the coronoid process in the mandible of a neonate is large and is located above the condyloid process. After birth, both halves of the jaw fuse. This process takes place in the mandibular symphysis, and moves from the bottom to the top. Because of the developing buds of permanent teeth, the corpus elongates posteriorly from the mental foramen. Together with the development of the alveolar part, the mandibular corpus height increases to make space for the elongating teeth roots. When the permanent teeth start to erupt, the mandibular canal is located just above the mylohyoid sulcus, and the mental foramen moves anteriorly, reaching its final place on the level of the second premolar tooth. The mandibular angle is less obtuse, and at the age of 4 has about 140º . When considering adults, the mandibular proportions are different, and the alveolar part of the mandible, as well as the base of the mandible are of similar height. The mandibular foramen moves cranially and positions itself in the centre of the corpus. The mandibular canal runs almost parallel to the mylohyoid line. The angle between the corpus and the ramus becomes more perpendicular, between 120º and 130º. In senile age, due to the loss of teeth, the size of the mandible decreases. The alveolar part undergoes atrophy. Due to those changes, the main part of the corpus is localised below the oblique line, and the mandibular canal together with the mental foramen relatively move upwards, running near the dental arch. The mandibular ramus leans posteriorly, thus the mandibular angle increases, and once again is about 140º. The neck of the condyloid process leans posteriorly (5),(6).

Mandible Innervation

Developmentally, both mandibular condyles are innervated by the third ramus of the trigeminal nerve , the mandibular nerve (7). This nerve is the one of the trigeminal branches and has a

mixed character. Its lower or posterior branch holds the sensory function and the upper or anterior one the motor function. The mandibular nerve innervates the mandible, the tempo-mandibular joint, the muscles, skin, mucosa, the periosteum, and all of the mandibular teeth. It exits the cranium through the oval foramen and goes posteriorly behind the lateral pterygoid muscle to the subtemporal fossa (8). The posterior group usually has three sensory branches namely, the lingual nerve, the inferior alveolar nerve and the auricotemporal nerve. The only sensory branch of the anterior group is the buccal nerve. It runs through the upper part of the subtemporal fossa and crosses the anterior edge of the mandibular ramus on the level of the upper molars (9). The inferior alveolar nerve is the only nerve from the posterior group that runs in the ossified mandibular canal. It branches off the posterior trunk, laterally from the lingual nerve, and runs between the medial and lateral pterygoid muscles (10). Next it goes caudally and anteriorly between the sphenomandibular ligament and the mandibular ramus, towards the mandibular foramen. The inferior alveolar nerve has both the sensory and motor components. Before entering the mandibular canal it gives off the mylohyoid nerve, which lies in the mylohyoid sulcus. Subsequently, after reaching the posterior edge of the mylohoid muscle, the mylohyoid nerve passes on its caudal surface, giving off motor branches to this muscle and to the anterior belly of the digastric muscle (11). The sensory branches reach the skin around the mental protuberance. This nerve sometimes can join the lingual nerve by a small branch piercing the mylohyoid muscle. Among the nerves in the immediate vicinity of the mandible that might be significant during standard anaesthesia, is the lingual nerve. Usually it passes between the heads of the lateral pterygoid muscle or between the lateral and medial pterygoid muscles. Then, it runs with the buccal artery on the lateral surface of the buccal muscle, until it reaches the angle of the mouth. They pierce the buccal muscle, but do not innervate him, and supply the buccal mucosa, and partially the gums. They also innervate the skin of the cheek, joining the branches of the facial nerve.

Knowing the site of the mental foramen allows for accurate delivery of local anesthesia for dental procedures and the avoidance of damage to the nerve in surgical procedures. It also aids in interpreting anatomical landmarks in forensic dentistry (12),(13). Panoramic radiographs were utilized in the present study to assess the mental foramen as it provides more wide and reliable field to view anatomy of the mandible as compared with periapical radiographs. Limitation of the present study was the use of panoramic radiographs for locating mental foramen instead of

commencing an anatomic study on skulls. In spite of clinical importance of mental foramen, it also offers importance in forensic application because mandibular characteristics are extremely useful in gender determination. Wical et al (14), Lindh et al (15), and Guler et al (16) commenced studies and reported that even with resorption of the alveolar bone above the mental foramen, the space from the foramen to the inferior border of the mandible remains relatively constant throughout life. Thus, stability of this part is not affected by resorption of alveolar process above the foramen. Chandra et al (17) concluded that the length from lower border of the mandible to the mental foramen exhibits sexual dimorphism, and panoramic radiography is an efficient tool for assembly of planned dimensions and can be measured as an added radiographic method to establish gender from the skeletal remains. Thakur et al (18), Mahima et al (19), and Naroor et al (20) reported the possibility that the height of the mandible and the distance from the mental foramen to the alveolar crest can be used to determine gender. In this research, the results shows that the distance between the mental foramen and the inferior border of the mandible is directly proportionate to age of the patient. It is seen that the distance is decreasing with ageing and this may be de to bone resorption that causes thinning of the inferior border of the mandible. Also, there is no significant difference of the distance between the mental foramen and base border of mandible seen in patients of selected age groups according to gender.

Conclusion

The results from the study revealed that the distance between the mental foramen and the inferior border of the mandible influences in determining the age and not the gender. Thus to conclude, the position of mental foramen does not play a role determining the gender and has significance in determining the age. Knowledge of both the position of the mental foramen and its distance from neighboring anatomical structures provides useful information for surgery and can also help to prevent complications, such as paresthesia. Further studies in populations of different races or ethnicities should be conducted to determine the position of the mental foramen, its role in determining age and gender and its distance from neighboring anatomical structures.

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Introduction: The Aim of this research to study the interarch and the intraarch relationship of the anterior teeth with periodontal conditions.This study is done to know the relationship between the orthodontic anomalies which is assessed using the IOTN index and periodontal conditions assessed by the plaque index and gingival bleeding index.

Materials and Methods: The three parameters of the intraarch relationship on both dental arches (displacement of contact point, crowding, spacing) and the four interarch relationship (overjet , overbite, crossbite) are assessed with index of orthodontic treatment need (IOTN) and are correlated with the periodontal condition, plaque index and the gingival bleeding index.

Result: A significant correlation was found between parameters of intraarch and interarch relationship and the indices of periodontal conditions such as plaque index, gingival bleeding index.

Conclusion: This study provides valuable indication on the usefulness of making orthodontic treatment on the ground of preservation of periodontal condition.

***Key Words**: gingival bleeding index, plaque index, orthodontic anomalies , interarch, intraarch.*

Introduction

The past decades have witnessed a steady increase of the children and the adults undergoing orthodontic treatment in most of the countries [1, 2].Improvement of facial and dental aesthetics are routinely cited to justify the provision of orthodontic treatment and also form the cornerstones of some orthodontic anomalies[4, 5]. The index of orthodontic treatment need (IOTN) records the treatment need on the basis of two components, a dental health component (DHC) and an aesthetic component. The DHC records the indications for the treatment on the ground of potential deleterious effects of malocclusion on the health and functioning of the dentition[6, 7]. The etiology and the pathogenesis of the periodontal disease are known to be multifactorial, but dental plaque is considered to be an essential precursor. So any factor presumed to promote the plaque retention or to make its removal difficult might contribute to periodontal disease[8, 9,15]. For example, crowding of the teeth creates areas hardly accessible to tooth brushing and has been recognized to make a thorough cleaning of the teeth laborious. Various types of malocclusions have also been correlated to increase plaque indices[10, 11]. This study was undertaken to further investigate the correlation between the interarch and intraarch relationship of the anterior teeth which is assessed by the IOTN and some of the periodontal conditions, ie, hygiene , gingival bleeding index and plaque index[12,13].

Periodontitis is a chronic bacterial infection characterized by persistent inflammation, connective tissue breakdown and alveolar bone destruction mediated by pro-inflammatory mediators. Tumor necrosis factor-alpha (TNF-α) is an important pro-inflammatory mediator that produced causes destruction of periodontal tissues[20]. The etiology and pathogenesis of periodontal disease are known to be multifactorial, but dental plaque is recognized as an essential precursor. Hence, any factor presumed to promote plaque retention or to make difficult its removal might contribute to the local risk of periodontal disease. For instance, crowding of teeth creates areas hardly accessible to tooth brushing and has been recognized to make a thorough cleaning of the teeth laborious. Various types of malocclusions have also been correlated to increased plaque indices.[13] On the other hand, many investigations failed to

demonstrate any significant correlation between tooth irregularities and periodontal state. In addition, some authors stressed that the enhancement provided by orthodontic treatment in terms of periodontal health may be of minor importance compared with maintenance of good oral hygiene. Also, recently, Geiger wondered about the available findings on the correlation between malocclusion and periodontal disease and emphasized the need for additional

quantitative studies to validate the predictability of malocclusion as an etiologic factor of periodontal disease.

This study was undertaken to further investigate the correlation between the intraarch and interarch relationships of the anterior teeth as assessed by the IOTN and the ICON and some parameters of periodontal conditions, ie, hygiene, inflammation , disease severity, and treatment need.[17]

Materials and Methods

Subject

The study population consists of a sample of 100 young adults (44 females and 56 males), aged 20 to 35 years with no history of orthodontic treatment. They were local people from different areas of Chennai, India, who had come for a dental checkup to saveetha dental college and hospital. They participated in the study on a voluntary basis after receiving comprehensive information about the aims and design of the study.

Inclusion Criteria

To be included in the study subjects needed to fulfill the following criteria: 1)possession of the six natural teeth of the anterior sextant (incisors and canines) in each arch2) manual tooth brushing once or twice a day3) knowledge about oral hygiene methods.

Exclusion Criteria

All the subjects who had undergone professional plaque removal and scaling in the past five months were not included in the study.

Assessment of Periodontal Condition

The study subjects were examined for evaluation of the periodontal conditions in the dental office under the optimal conditions with a periodontal probe and a mouth mirror. Parameters related to the periodontal status were assessed directly in the upper and lower anterior sextant of both the maxillary and mandibular arches. These include the oral hygiene index by Greene and Vermillion 1960 and the gingival bleeding index by Ainamo and Bay 1975.

Oral Hygiene: The oral hygiene status was evaluated by measuring the amount of soft and mineralized deposit present on the tooth surface. The plaque was calculated on all the four surfaces labial , lingual , mesial and distal of both the incisors and the canines. . Cavities and restorations were not considered. The plaque was measured by the plaque index Silness and Loe in 1964 on all the four surfaces, and the mean score was obtained by dividing it by 4 for

each tooth. They are measured for all the 6 anterior teeth both in the upper jaw and the lower jaw and the mean score is obtained by dividing it by 6

Plaque Index : Plaque index by Silness and Loe certains the thickness of the plaque along the gingival margin; plaque plays an etiology of gingivitis13, 14.

Gingival Inflammation : the gingival inflammation was assessed by the gingival index (GBI). The gingival bleeding index is recorded after a gentle probing on the mesial, midline, and distal on the labial and the lingual surface of the each targeted teeth. Intraarch and Intraarch Relationship Parameters

The interarch and the intraarch relationship was assessed on the anterior sextant (teeth 13 to 23 and 33 to 43) by the IOTN index.

Result

The plaque index was calculated for all the samples and the mean value was taken separately for the male and female. The result shows that the female have lesser plaque when compared to the male. The oral hygiene of the female is better when compared to male. The mean value obtained for females in the upper anterior teeth is 0.83 ± 0.24 (MEAN + SD) and for the lower anterior teeth is 1 ±0.1(MEAN+SD). In case of males the plaque index is comparatively more, the upper anterior teeth have an average plaque index of 1 ± 0.34 and for the lower anterior teeth it is 2.12 ± 1.22 (MEAN + SD). The plaque index score is tabulated in table 1

Table 1: Comparison of Plaque Index and gingival bleeding index for Male and Female in the upper arch .

Periodontal Conditions	Male		Female	
Upper Arch	(Mean±SD)	Interpretation	(Mean±SD)	Interpretation
Gingival bleeding index	1.25 ± 0.353	moderate gingival inflammation	1.05 ± 0.212	Slight gingival inflammation
Plaque Index	1 ± 0.34	Average plaque control	0.83 ± 0.24	Very slight amount of plaque

The gingival bleeding index was taken for all the patients and they are recorded in the Performa. The mean of the gingival bleeding index was taken for the female upper arch and lower arch and male upper arch. The mean value of the gingival bleeding index for the female upper arch is 1.05 ± 0.212 and the gingival bleeding index for the female lower arch is 1 ± 0.12. The gingival bleeding index for the males is comparatively more than the females. The male upper arch has a mean value of 1.25 ± 0.353 and the lower arch has a mean value of 2 ± 1.414. The statistical analysis has shown the males have higher gingival bleeding index and plaque index when compared with females. The gingival bleeding index score is tabulated in table 2.

Table 2: Assessment of Gingival Bleeding Index and Plaque Index in the Lower Arch.

Lower Arch	(Mean ± SD)	Interpretation	(Mean ± SD)	Interpretatio
Plaque Index	2.12 ± 1.22	Severe plaque present	1 ± 0.1	Slight amount plaque
Gingival bleeding Index	2 ± 1.414	Severe gingival inflammation	1 ± 0.12	Moderate gingival inflammatio

The statistical analysis for the IOTN grading and the periodontal condition was done. Out of 100 patients 18 patients had minor malocclusion, including the contact point displacement less than 1mm. which belongs to grade 1. 20 patients had anterior and posterior open bite greater than 2mm but less than or equal to 4mm belongs to grade 2. 17 patients had increased overbite greater than 3mm with incompetent lips which belongs to grade 3. 5 patients had less extensive hypodontia requiring orthodontic space closure in upper anteriors which belongs to grade 4.

Rest of the 35 patients had impeded eruption of teeth due to crowding, displacement, presence of supernumerary teeth. The mean of the gingival bleeding index and the plaque index was calculated for each condition and is tabulated below

Table 3: Comparison of IOTN condition with Gingival bleeding Index and Plaque Index

IOTN Condition	PlaqueIndex (Mean±SD)	Condition	Gingival Bleeding Index (Mean±SD)	Condition
Grade 1 minor malocclusion, including the contact point displacement ≤1mm	0.5 ± 0.121	Very minimum plaque	1.1 ± 0.622	Less gingival inflammation
Grade 2 anterior and posterior open bite ≥ 2mm but ≤ 4mm	1.12 ±0.1	Moderate plaque	1.23 ± 0.322	Moderate gingival inflammation
Grade 3 increased overbite ≥ 3mm with incompetent lips	1.32 ± 0.32	Moderate plaque	2.1 ± 1.414	Moderate gingival inflammation
Grade 4 less extensive hypodontia requiring orthodontic space closure	0.93 ± 0.12	Very minimum plaque	1.32 ± 0.32	Less gingival inflammation
Grade 5 crowding , displacement , presence of supernumerary teeth	2.31 ± 1.11	High amount of plaque	3.22 ± 1.52	Severe gingival inflammation

Discussion

In case of males the plaque index is comparatively more, the upper anterior teeth have an average plaque index of 1 ± 0.34 and for the lower anterior teeth it is 2.12 ± 1.22 (MEAN + SD). The statistical analysis has shown the males have higher gingival bleeding index and plaque index when compared with females. The statistical analysis shows, for grade 1, minor malocclusion, including the contact point displacement less than or equal to 1mm there is very minimum plaque present and less gingival inflammation. In grade 2 , the anterior and posterior open bite less than or equal to 2mm but greater than 4mm there is moderate plaque and also moderate gingival inflammation. In grade3, increased overbite greater than 3mm with incompetent lips there is moderate amount of plaque and also gingival inflammation. In grade 4, less hypodontia requiring orthodontic space closure, there is very minimum amount of plaque and also very gingival inflammation. In grade 5, where there is crowding, displacement

, presence of supernumerary teeth there is high amount of plaque and also severe gingival inflammation. It shows that in crowding case the patients show high amount of plaque which is because the brushing cannot clear all the plaque due to the presence of tooth displacement and the presence of supernumerary teeth.

Varying degrees of correlation have been found between intraarch relationship and periodontal condition depending on the arch and the indices taken into account. Overall, it appears that, despite a normal hygiene regimen, the presence of malpositioned and crowded teeth in the mandibular arch is associated with difficulties in plaque removal and gingival inflammation. On the other hand, these parameters ranked lower in the maxillary teeth18,19 Comparisons with previous studies are complicated by virtue of the differences in methodological approaches and the indices used to assess both the periodontal and the occlusal conditions. Ingervall et al also studied the relationship between crowding of teeth and gingival condition in a smaller sample of dental students of almost the same age bracket, as in subjects of this study. They found that crowding of teeth (tooth displaced by two mm or rotated for at least 15) did not favor plaque accumulation on proximal tooth surfaces and influenced gingival inflammation only slightly20 Geiger et al1also found no significant correlation between crowding and periodontal condition21. On the other hand, Buckley in a study of 300 teenagers reported a low but significant correlation in the range of that found in this study between lower

incisor crowding as assessed by the Occlusal Feature Index, the PlI and the GI. The reason why crowding, although significantly correlated with hygiene and inflammation, is not correlated to disease severity is elusive. However, it is noteworthy that although gingivitis must precede periodontitis, not all gingivitis progresses to periodontitis22.

Conclusion

A significant correlation was found between certain parameters such as the gingival bleeding index, the plaque index with intra-arch and inter-arch relationship of the anterior teeth and periodontal conditions. This study provides valuable indication on the usefulness of making orthodontic treatment on the ground of preservation of periodontal condition.

Invitro Antibacterial Activity of Acacia Catechu and RosmarinusOfficianalison Streptococcus Mutans.

S.Pooja[1], Geetha RV[2], Geo Mani[3],
Graduate Student[1], Reader[2],Department of Microbiology, Senior Lecturer[3], Department of Pedodontics
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,Saveetha University, Chennai, India

Abstract

Introduction: Dental caries is steadily increasing in the underdeveloped and developing countries. S*treptococcus mutans* is a potent initiator of caries and various oral problems. The usage of these herbal extracts can be beneficial to the patients in maintaining the oral hygiene Herbal extracts have been found more useful in curing number of diseases including bacterial diseases leading to a rich source of antimicrobial agents. *Rosmarinus officinalis* belongs to *lamiaceae*family of herbs which is used as a food flavouring and medicinally known for its antibacterial properties. *Acacia catechu* which belongs to *Fabaceae*family of herbs is highly known for its powerful antibacterial and antioxidant activities.The aim of this study is to estimate the antibacterial activity of leaf extract Acacia catechu and Rosmarinus officinalis on streptococcus mutans.

Materials and Method: The antibacterial activity of leaf extract of Acacia catechu and Rosmarinus officinalis on Streptococcus mutans was screened using disc diffusion technique.

Results: The results of our present study shows the two extracts used have good antibacterial action on *Strepococcusmutants.*

Conclusion: Theuse and efficacy of medicinal plants contribute to their therapeutic properties, so that they are frequently prescribed.

Key Words*: Dental caries, anti bacterial, disc diffusion technique*

Introduction

The mouth cavity contains many microorganisms responsible for various infections and inflammatory diseases. The formation of dental caries is caused by the accumulation and colonization of oral microorganisms, especially *S. mutans* which adhere to and colonize the surface of teeth. Dental treatments in many countries are expensive and not easily accessible; therefore, people have turned to the use of medicinal plants in the form of composition of tooth paste, or simply chewing the plants directly to protect the teeth from diseases. Different plant species of medicinal importance have successfully been included

in mouthwashes and toothpastes in many developing countries.

Acacia catechu has a place with Family Fabaceae and subfamily Mimosoideae (1).The concentrates of Acacia catechu shows different pharmacological impacts like antipyretic, calming, antidiarrhoeal, hypoglycaemic, hepatoprotective, cell reinforcement and antimicrobial activities(2).Acacia catechu is exceptionally significant for its capable astringent and cancer prevention agent activity(3).Main substance constituents of Acacia catechu willd are catechin, (-)epicatechin, epigallocatechin, epicatechingallate, epigallocatechingallete,rocatechinphloroglucin,protocatechuic corrosive, quercetin, Porifera sterolglucosides, Poriferasterolacyglucosides, lupenone, lupeol, procynadinAC, kaempferol, dihydrokaemferol, taxi folin, (+)- afzelchin gum and mineral (4). Acacia catechu is useful as a topical agent for sore gums and mouth ulcers(5).oral bacteria like *Streptococcus mutans* is an potent initiator that causes dental caries/plaques(6).*Rosmarinus officinalis* (Rosemary) have been known to have antimicrobial, antioxidant, anti-diabetic, and anti-tumorigenic activities (7).In addition, it is known to affect the cell's adhesive properties, self-aggregation, and protein secretion; and this might help in the treatment of cardiovascular diseases andthrombosis .*Rosmarinus officinalis* have anticancer properties . Rosmarinus officinalis (Rosemary) was generally utilized for the treatment of a few diseases, for example, urinary tract contaminations, rheumatoid cholecystitis, loose bowels, and hypertension (8).Among the pharmacologically approved restorative employments of rosemary are antibacterial, anticancer ,antidiabetic, against inammatory and antinociceptive, cell reinforcement , antithrombotic , antiulcerogenic, enhancing subjective , antidiuretic , and hepatoprotective. other significant utilization of rosemary is in the perfumery business where the fundamental oils are utilized as normal elements of fragrances(9). Fundamental oils of rose-mary ruled by 1,8-cineole, α-pinene, camphene, α-terpineol, and borneol as key constituents are additionally in charge of different pharmacological impacts of the general cancer prevention agent and antimicrobial properties known for some, basic oils, and additionally other e ects including anticarcinogenic activities(10). *S. mutans* is common flora of human mouth that has polysaccharide capsule and has important rule to produce dental caries (11).Short chain carboxylic acid released from the enzymes of streptococcus mutans used as its fermentation by-products demineralize the enamel and lead to cavitation in the tooth. Hence considered to be the most cariogenic of all streptococci family(12). Hence the aim of this study is to estimate the antibacterial activity of *Acacia catechu* and *Rosmarinus officinalis* on *streptococcus mutans.*

Materials and Methods(13-15)

Test Microorganism

Bacterial strain used was Streptococcus mutans. The living being was secluded utilizing particular media Mutans - Sanguis agar [Hi media M977], and kept up in supplement agar slant at 4°C in branch of Microbiology, Saveetha Dental College.

Methodology

The leaf extracts of *Acacia catechu* and *Rosmarinus officinalis* were dissolved in distilled water in following concentrations 2.5mg/ml, 5mg/ml and 10mg/ml so that 100µl delivers

250µg/ml, 500µg/ml and 1000 µg/ml respectively .100µl of the extract were loaded on sterile filter paper discs measuring 6mm. The discs were dried and kept aseptically.

Screening of Antibacterial Activity [Disc diffusion technique]

Broth culture of the bacterial strain compared to Mac Farland's standard [4,5,6] 0.5 was prepared. culture of the test creatures were made on the Muller Hinton agar [MHA-Hi media M1084] plates utilizing sterile cotton swab and the plates were dried for 15 minutes.Filter paper discs loaded with different concentrations of the extract were placed on the respective plates. The plates were incubated at 37°C overnight and the zone of inhibition of growth was measured in millimeters. All the tests were done in triplicate to minimize the test error.

Result

Table 1: Anti-bacterial activity of *Acacia catechu* and *Rosmarinus officinalis*on Streptococcus mutans

Organism	Concµg/ml	E1 [Zone of inhibition in mm diameter]	E2 [Zone of inhibition in mm diameter]	Chlorhexidine [Zone of inhibition in mm diameter]
Streptococcus mutans	250	16	09	22
	500	19	14	30
	1000	26	22	38

E 1 – *Acacia catechu* E2 - *Rosmarinus officinalis* ,

The antibacterial movement of the fundamental oils at various fixations was screened by plate dispersion procedure and the zone of hindrance was measured in mm distance across.The results are given in the table 1. Acacia catechu leaf extract was more effective against *Streptococcus mutans* with a zone of inhibition of 26mm diameter (at conc1000 µg/ml.), *Rosmarinus officinalis* showed a zone of 22mm diameter . The use of natural antimicrobials may contribute to control the disordered growth of oral microbiota, thus overcoming problems caused by species resistant to conventional antimicrobials.

Discussion

Oral cavity is a complex ecosystem with higly divergent acid tolerant and acid-producing microbiota. Bacteria accumulate on both the hard andsoft oral tissues in biofilms(16). The primary acid tolerant bacteria associated with Dental plaqueincludes streptococcus mutans(17). The ethanolic bark extract of Acacia catechu has a antibacterial activity against streptococcus mutans(18).Acacia catechu Willd is widely used in Ayurveda for many diseases and mainly for skin diseases.Acacia catechu is very significant for its

effective astringent and cancer prevention agent exercises. It is ordinarily known as Katha which is a key element of Pan that is insect leaf readiness bit in India. It is helpful in Dental, oral, throat diseases and as an astringent for lessening overflowing from endless ulcers and wounds(19). In stomatitis, halitosis, dental caries and cavities, halitosis, dental caries and cavities, Acacia catechu is used with great benefit(20). Moreno et al. (2006) detailed that rosemary plants are rich wellsprings of phenolic mixes with high antimicrobial action against both Gram-positive and Gram-negative microscopic organisms. Plainly rosemary removes have bioactive properties, yet their antimicrobial exercises have not been profoundly described.Ouattara et al. (1997) researched the antibacterial movement of chose fundamental oils against some sustenance deterioration living beings. They reasoned that the fundamental oils of cinnamon, clove and rosemary were the most dynamic. Comparative outcomes were acquired by Valero and Salmeron (2003) for the antibacterial movement of rosemary basic oil against Bacillus cereus strains developed in carrot juices. Numerous mixes have been disengaged from rosemary, including flavones, diterpenes, steroids, and triterpenes. Of these, the cell reinforcement movement of rosemary removes has been basically identified with two phenolic diterpenes: carnosic corrosive and carnosol(24). Rosemary basic oil is an antimicrobial source and substance blend whose cancer prevention agent properties and antimicrobial impacts have been demonstrated in different inquires about. For instance, phenolic compound is found in rich. Basic oil is one of the principle mixes of this herb which exists in 1-2%(25). It comprises of borneole, limonene, camphene, camphor and different mixes like phenolic corrosive including rosmarinic corrosive, caffeic corrosive and chlorogenic corrosive. Antimicrobial impacts of rosemary fundamental oil and concentrate on different microorganisms have been examined. Jarrar et al. analyzed the impact of ethanol concentrate of rosemary alone and with cefuroxime on methicillin safe staphylococcus(26).

Natural substances have demonstrated antibacterial action mainly because most plants used in alternative medicine are composed of flavonoids, which act on bacterial cells disrupting the cytoplasmatic membrane and inhibiting the enzymatic activity. In our present study the two extracts used have goodanti microbial action on Strepococcus mutans. A study byEllon et.al showed that*A. catechu* leaves have still exerted some degrees of inhibition against Gram-negative organisms(27). Another study by Anitha Roy et.al showed that higher concentration of the extract showed good antifungal activity against all the fungal strains tested(28). A study by Morrissey et.al evaluated the antibacterial and antifungal potential of leaf extract of *A. catechu* so the use of this plant as an anti-infective agent in the ayurvedic medicine has been justified(29).

Conclusion

The use of plants for treating diseases is as old as the human species. Famous perceptions on the utilization and adequacy of restorative plants altogether add to the revelation of their remedial properties, with the goal that they are as often as possible endorsed, regardless of whether their compound constituents are not generally totally known. The consequences of our present examination demonstrates the two concentrates utilized have great hostile to bacterial activity on Streptococcus mutants. These plants have potential for improvement of antimicrobial operators against oral microorganisms, for use in tooth glue, mouth wash and so forth to prevent and treating oral contaminations.

Abstract

Introduction: The objective of our study is to investigate the in vitro antibacterial activity of acetone leaf extract of Azadirachta Indica and Uva ursiagainst selected oral microbes that causes dental plaque in fixed orthodontic appliance patients.Herbal based compounds plays a vital role in dentistry. Orthodontic patients wearing fixed orthodontic appliances have dental plaques which may induce gingivitis too,Azadirachtaindica ,Uvaursi commonly known as neem possess significant anti-inflammatory and anti cariogenic activity, hence it can be recommended for these patients.

Materials and Methods: The inhibitory effect of acetone leaf extract of Azadirachta indica and Uva ursi were tested against streptococcus mutans,streptococcus salivarius,streptococcus mitis by using the Broth culture method.

Results: The acetone leaf extract of Azadirachta indica exhibited significant antibacterial activity against streptococcus mutans and streptococcus mitis with minimum bactericidal concentration of 62µg/ml whereas, Uva ursi acetone leaf extract showed antibacterial activity against streptococcus mutans streptococcus mitis ,streptococcus salivarius at concentration of 1mg/ml.

Conclusion: The acetone leaf extract ofAzadirachta indica and Uva-ursi were found to be bactericidal in action against tested bacterial strains.

Key Words:*Azadirachta indica, Uva ursi, anti bacterial activity, MBC, oral microbes ,orthodontic fixed appliance ,dental plaque*.

Introduction

Human dental plaque was one of the ecosystem. which microorganism was firstobserved. Dental plaque refers to the colonies of bacterial cell embedded in a protein matrix and polysaccharide which adheres to the surface of teeth by a characteristic bacterium.[1]Dental caries/plaque is a chronic disease of multifactor etiology and pathogens.[2] The early stage of dental caries is characterized by a destruction of superficial dental structures caused by acids which are by-products of carbohydrate metabolism by streptococcus mutans .[3] Teeth affected with dental caries are sources of infection, which can cause an inflammation of dental pulp, periodonteum and gums. If left untreated, this disease gradually leads to teeth loss, which causes chewing difficulties and aesthetic problems. [4]

The major role in prognosis and development of oral diseases is played by streptococci species from mutans group. These microorganisms shows their action of initiation of caries with the formation of the dental biofilm i.e. dental plaque.[5]acidogenic oral bacteria like streptococcus mutans, streptococcus salivarius, streptococcus mitis,streptococcus sanguis primarily causes dental caries/plaque (Lakshmi .T et al ., 2011)that surround orthodontic appliances in many patients undergoing orthodontic treatment [6] Such bacteria can lead to tooth enamel breakdown and potential discoloration of the tooth surface, and these aesthetic changes can persist for many years after orthodontic treatment[7,8]

It also has been reported that thepresence of fixed orthodontic appliance greatlyaffects oral hygiene and creates new retentive areas for plaque and debris [7] ,which in turn predisposes to increased carriage of microbes and subsequent infection .Therefore, prevention of bacterial attachment to orthodontic appliance is a critical concern for orthodontists[8,9]. The use of natural products has been one of the most successful strategies for the discovery of new drugs.

Azadirachta Indica commonly known as Neem which is used to treat various disease condition. Every part of the tree is used as traditional medicine for household remedy against various human ailments, from ancient period[10-15]. Nimbidin, a major crude bitter principle extracted from the oil of seed kernels of A. indica demonstrated several biological activities. Studies shows that Neem leaf extract is used to treat dental plaque and gingivitis.

Uva ursi (Arctostaphylos uva ursi), also known as bearberry because bears like eating the fruit, possess medicinal value. Native Americans used it as a remedy for urinary tract infections.[16] In fact, until the discovery of sulfa drugs and antibiotics, uva ursi was a common treatment for such bladder and related infections. The herb also contains tannins that have astringent effects, helping to shrink and tighten mucous membranes in the body. That, in turn, helps reduce inflammation and fight infection(Lakshmi .T et al .,2012).Uva ursi leaves are used for treatment of disease conditions not the berries.[17]

Several literature review proves that plants as intact crude organs and their products (e.g., powdered plants, extracts, etc) have been widely used by different cultures to promote oral hygiene since antiquity. Hence an attempt was taken in this study to evaluate the antibacterial efficacy of Azadirachtaindica and uvaursiinvitro against selected oral microbes inorder to control dental plaque that seems to be difficult to get removed by mechanical device in fixed appliance patients undergoing orthodontic treatment.

Materials and Method

Plant Material

Acetoneleafextract of Azadirachtaindica and Uvaursiwere collected from Hosur,

Tamil Nadu and were authenticated by Green Chem lab, Bengaluru ,India.

Preparation of Acetone Extract

Leaves were shade dried for a week. Dried leaves were milled to fine powder. Powder was passed through 100 mesh sieve and stored in a sealed polythene bag.2.5kg of powdered plant material were extracted with 10 liters of acetone at 65°C temperature, for 1 hour, in a 20 liter round bottom flask with Graham condenser attached. Condenser was cooled circulating with chilled water. After 1 hour of extraction, round bottom flask was cooled to room temp and the extract were filtered and collected. The Marc was extracted repeatedly with 10 liters of acetone, twice. The extracts were filtered and collected. The combined extracts was evaporated to dryness under reduced pressure in a Buchi Rotary Evaporator (Switzerland) at 65°C, to obtain 150g of powder extract. The w/w yield of the prepared extract was 6%. The extract were stored at 4 °C until used.

Test Microorganisms

Bacterial strains used were streptococcus mutans (ATCC 25175) ,streptococcus salivarius (ATCC 25975),streptococcus mitis (ATCC 9811) The organisms were obtained from Department of Microbiology , Saveetha Dental College & Hospitals, Chennai .

Methodology

The plant extract 200mg were weighed aseptically into a sterile tube and dissolved in 2ml of sterile Tryptic soy Broth (TSB).From the stock solution various concentrations were prepared,viz.,62µg,125 µg,250 µg,500 µg/100µl ,1mg,5mg,10mg/100µl respectively in to wells of micro plates.100µl of these concentration were taken and the plates were incubated at 37°C for 24hrs.

Screening of Antibactericial Activity

The tested organisms was grown in (TSB) Tryptic soy broth medium [Hi media ,Mumbai] for 24hrs at 37°C and concentration was adjusted to 0.5 Macfarland standard.[18-20]The above concentration of extracts were taken in 100µl quantities in a U bottom micro culture plates. 100µl of the bacterial suspension was added to each well.control well received plain broth without plant extract. The plates were kept in sealed covers and incubated at 37°C overnight and growth/no growth was detected. All the tests were done in duplicate to minimize the test error.

Minimum Inhibitory Concentration (MIC)

Minimum inhibitory concentration of herbal extracts against tested microorganism was determined by broth culture method .[21]A series of two- fold dilution of each extract
(62 µg/100µl to 10mg/100µl) was made in to which 100µl of the standardized bacterial suspension containing 10^6 organisms was made in Tryptic soy broth as specified by National Committee for Clinical Laboratory Standards (NCCLS, 1990)[22]The control well received plain broth without herbal extract .The plates were incubated at 37°C for 24 hours and observed for visible growth. As the extracts were colored, MIC could not be read directly by visual methods. Hence subcultures from all the wells were made and growth/no growth is detected.then the MBC were obtained.

Minimum Bactericidal Concentration (MBC)

The MBCs were determined by selecting wells that showed no growth. The least concentration, at which no growth was observed, were noted as the MBC.

Result and Discussion

Dental plaque, the biofilm that forms on the surface of teeth, can induce some of the most common diseases which include caries, gingivitis, and periodontitis. Acid-producing bacteria like streptococcus mutans, Lactobacillus acidophilus, streptococcus salivarius, Streptococcus mitis that surround orthodontic appliances are a common orthodontic problem in many patients undergoing Orthodontic treatment .[23,24] Such bacteria can lead to tooth enamel breakdown and potential discoloration of the tooth surface, and these aesthetic changes can persist for many years after orthodontic treatment. While the newer bonded orthodontic brackets have many advantages over the old metal bands that were fitted around each tooth, they do impede good oral hygiene, resulting in plaque accumulation and increased tooth enamel breakdown.

Prashanth et al conducted a study to evaluate the antimicrobial effects of the chewing sticks of Neem and mango against the micro organisms like Streptococcus mutans ,Streptococcus salivarius , Streptococcus mitis , Streptococcus sanguis which are involved in the development of dental caries. His data concluded that, Mango extract showed maximum zone of inhibition on Streptococcus mitis. Neem extract produced the maximum zone of inhibition on Streptococcus mutans. Even at low concentration neem extract showed some inhibition of growth for all the four species of organisms. Hence combination of neem and mango chewing sticks may provide the maximum benefit to mankind to prevent dental caries.[25]

Venka A et al conducted a study related to the antibacterial effect of Neem mouthwash against salivary levels of streptococcus mutans and Lactobacillus Acidophilus has been tested over a period of two months. Also its effect in reversing incipient carious lesions was assessed. He found that streptococcus mutans was inhibited by Neem mouthwashes, with or without alcohol as well as chlorhexidine, lactobacillus growth was inhibited by chlorhexidine alone. [26,27]

Beukes an orthodontist conducted an invitro study on the antimicrobial activity of phytomedicin against acidogenic oral bacteria on eight medicinal plants like Hydrastis Canadensis, CyclopiaIntermedia, Hypericum perforatum, Ginkgoaceae, Passiflora incarnata, Achillea Millefolium,Arciosiaphylos uva-ursi and Artemisia absinthium against S. mutans, S. sobrinus, L. casei and A.naeslundii involved in dental demineralisation., acetone, ethanolic, hexane form of extract wereUsed.The control treatments were chlorhexidine and fluoride.[28,29] His findings concludes that the acetone extracts of that includes Ginkgoaceae, Achillea Millefolium, Passiflora incarnata, Arciosiaphylos uva-ursi and Hypericum

perforatum showed significant inhibition zones against S.mutans, L.casei and S.sobrinus when compared to ethanolic and hexane extract.[30,31]

Hence our finding suggests the presence of No growth is an indication of high effectiveness of the extract whereas presence of Growth indicates the less effectiveness of the extract, which was represented in Table 1 .

Azadirachta indica leaf extract shows No growth (MBC) at a concentration of 62µg/ml against streptococcus mutans and streptococcus mitis. Uvaursi extract showed No growth at a concentration of 1mg/ml.whereas in table 2 Azadirachta indica shows No growth (MBC) at a concentration of 5mg/ml against streptococcus salivarius.Uvaursi leaf extract showed No growth at a concentration of 1mg/ml in conclusion,Azadirachtaindica leaf extract is highly effective against streptococcus mutans and streptococcus mitis when compared to Uva ursi leaf extract. On other hand Uva ursi leaf extract is found to efficient against streptococcus salivarius than Azadirachta indica leaf extract.

Table 1: Antibacterial Activity of Phytomedicine against Oral Microbes

Oral microbes	Herbal extract	62µg/ml	125 µg/ml	250 µg/ml	500 µg/ml	1mg/ml	5mg/ml	10mg/ml	Control	MIC/ MBC
S.mutans ATCC-25175	A.indica	--	--	--	--	--	--	--	++	62 µg/ml
	A.Uvaursi	++	++	++	++	--	--	--	++	1mg/ml

S.Salivarius ATCC-25975	**A.indica**	++	++	++	++	++	--	--	++	**5mg/ml**
	A.Uvaursi	++	++	++	++	--	--	--	++	**1mg/ml**
S.mitis ATCC-9811	**A.indica**	--	--	--	--	--	--	--	++	**62 µg/ml**
	A.Uvaursi	++	++	++	++	--	--	--	++	**1mg/ml**

++ = Growth -- = No Growth (Indicates the MIC/MBC)

Conclusion

Various literature reveals the antibacterial activity of Neem and Uva-ursi against oral bacteria. no work is done on the Neem leaf and Uvaursi acetone extract against acidogenic oral bacteria.hence our data proves the antibacterial efficacy of the acetone leaf extract of **Azadirachta indica**,and **Uva ursi** is an indicator of its broad spectrum antibacterial potential which may be helpful in eradicating streptococcus mutans and streptococcus mitis and provides an aid to control dental plaque . However, further studies are necessary to isolate and reveal the active compound(s) contained in the refined extract of Azadirachta indica and Uvaursiand to establish the mechanism of action.

Is Periodontitis an Indicator for Diabetes Mellitus

N.S.Harini[1], Vivek Narayan[2], Sankari M[3]

Graduate Student[1], Reader[2], Department of Oral Medicine, Professor[3], Department of Periodontics.

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,Saveetha University, Chennai, India

Abstract

Introduction: Diabetes and periodontitis are multifactorial chronic inflammatory diseases affecting a very large population. Periodontitis can be used as a predictor for diabetes and pre-diabetes risk assessment.The manifestations of diabetes mellitus are widespread among which periodontitis is the most common oral manifestation and the two diseases appear to be interrelated. There is increased inflammation in diabetes which leads to increased prevalence of periodontitis in diabetes patients.The present study is aimed at finding out presence of diabetes mellitus in patients with periodontits, so that periodontitis could be used as an indicator for diabetes mellitus.

Materials and Methods: This study has a sample size of 50 and the patients were taken from Saveetha Dental College and Hospitals. This study involves among periodontally compromised patients to determine the presence of diabetes mellitus among them by using glucometer to assess their random blood sugar level (RBS LEVEL). Once the RBS was calculated, the patients' periodontal status was evaluated. Finally the periodontitis and diabetic level of the patients were correlated. The results were then statistically analysed and tabulated using bar graphs and the correlation was estimated.

Results: According to the survey, among 50 periodontally compromised patients, 22 patients were males, and 28 patients were females. Among these 50 periodontally compromised patients, under 20-30 years of age category 5 were males and 4 were females. 31-40 years of age group contained 4 males and 7 females. Under the age group of 41-50 years of age 4 were males and 3 were females. The age group of more than 50 years contained 10 males and 13 females.

Conclusion: Thus, the survey has shown positive results where periodontitis is an indicator for diabetes mellitus. The age distribution favourable for the condition is more than 50 years of age and the gender ratio is that females are more prone than males. For the diabetic status, awareness must be created among people to check their blood glucose level periodically.

Key Words*:Diabetes mellitus, Periodontitis, glucose level, periodontium, random blood sugar level.*

Introduction

Diabetes and periodontitis are multifactorial chronic inflammatory diseases affecting a very large population. Studies have shown that there is a significant relationship between the two diseases, as diabetes is associated with increased prevalence, severity, and progression of periodontitis. Periodontitis can be used as a predictor for diabetes and pre-diabetes risk assessment[1] Diabetes Mellitus is a metabolic disorder affecting carbohydrate, lipid, and protein metabolism. The manifestations of diabetes mellitus are widespread among which periodontitis is the most common oral manifestation and the two diseases appear to be interrelated. There is increased inflammation in diabetes which leads to increased prevalence of periodontitis in diabetes patients.[2].

Diabetes mellitus is a systemic disease with several major complications affecting both the quality and length of life. One of these complications is periodontal disease (periodontitis). Periodontitis is much more than a localized oral infection. Recent data indicate that periodontitis may cause changes in systemic physiology. The interrelationships between periodontitis and diabetes provide an example of systemic disease predisposing to oral infection, and once that infection is established, the oral infection exacerbates systemic disease[3]. In this case, it may also be possible for the oral infection to predispose to systemic disease.

In order to understand the cellular/molecular mechanisms responsible for such a cyclical association, one must identify common physiological changes associated with diabetes and periodontitis that produce a synergy when the conditions coexist. A potential mechanistic link involves the broad axis of inflammation, specifically immune cell phenotype, serum lipid levels, and tissue homeostasis. Diabetes-induced changes in immune cell function produce an inflammatory immune cell phenotype (upregulation of proinflammatory cytokines from monocytes/polymorphonuclear leukocytes and downregulation of growth factors from macrophages). This predisposes to chronic inflammation, progressive tissue breakdown, and diminished tissue repair capacity[4,5]

Periodontal tissues frequently manifest these changes because they are constantly wounded by substances emanating from bacterial biofilms. Diabetic patients are prone to elevated low density lipoprotein cholesterol and triglycerides (LDL/TRG) even when blood glucose levels

are well controlled. This is significant, as recent studies demonstrate that hyperlipidemia may be one of the factors associated with diabetes-induced immune cell alterations. Recent human studies have established a relationship between high serum lipid levels and periodontitis. Some evidence now suggests that periodontitis itself may lead to elevated LDL/TRG[6-8]

Periodontitis-induced bacteremia/endotoxemia has been shown to cause elevations of serum proinflammatory cytokines such as interleukin-1 beta (IL-1 beta) and tumor necrosis factor-alpha (TNF-alpha), which have been demonstrated to produce alterations in lipid metabolism leading to hyperlipidemia. Within this context, periodontitis may contribute to elevated proinflammatory cytokines/serum lipids and potentially to systemic disease arising from chronic hyperlipidemia and/or increased inflammatory mediators[10,11]

These cytokines can produce an insulin resistance syndrome similar to that observed in diabetes and initiate destruction of pancreatic beta cells leading to development of diabetes. Thus, there is potential for periodontitis to exacerbate diabetes-induced hyperlipidemia, immune cell alterations, and diminished tissue repair capacity. It may also be possible for chronic periodontitis to induce diabetes[12-15]

The present study is aimed at finding out presence of diabetes mellitus in patients with periodontits, so that periodontitis could be used as an indicator for diabetes mellitus.

Materials and Methods

This study has a sample size of 50 and the patients were taken from Saveetha Dental College and Hospitals. This study involves among periodontally compromised patients to determine the presence of diabetes mellitus among them by using glucometer to assess their random blood sugar level (RBS LEVEL).The glucometer is used by pricking the patient’s ring finger and utilising a drop of their blood in the test strip and the value is obtained immediately which helps to determine the RBS level. Once the RBS was calculated, the patients’ periodontal status was evaluated by estimating probing depth, bleeding, attachment loss, furcation and mobility. Finally the periodontitis and diabetic level of the patients were correlated. The results were then statistically analysed and tabulated using bar graphs and the correlation was estimated.

Discussion

Periodontal disease is the most prevalent disease of the oral cavity. The role of aging in periodontal disease is debatable, but the means of preventing periodontal disease are available[16-18].Periodontitis is a chronic inflammatory disease that results in the loss of connective tissue and alveolar bone support of the teeth [36]. Periodontitis is a chronic bacterial infection characterized by persistent inflammation, connective tissue breakdown and alveolar bone destruction mediated by pro-inflammatory mediators [37].Inflammation and tissue breakdown are led by an array of inflammatory destructive mediators associated with initiation and progression of inflammatory diseases like periodontitis [38].

Diabetic patients are more prone to periodontal diseases as they are more susceptible to infections. Studies have proved that periodontitis can be considered as a complication of diabetes[39].An increased concentration of MMP-8 and -9 in the gingival tissue of diabetic CP patients suggests that the expression of these MMPs contributes to the failure of the healing process in the diabetic condition [40]. In the present study, the survey has shown that females above the age of 50 are more prone for periodontal problems.

Sexual dimorphisms exist in the prevalence and severity of many human conditions and diseases. Risk assessment is a crucial component of personalized medicine in evidence-based clinical practice. Gender is known to be a modifier of the initiation & outcome of many conditions. [19]. Though studies show thatmales are prone to periodontitis our study reveals that females with periodontitis are more for diabetes mellitus.

The relationship between diabetes mellitus and periodontal disease is not clear, even though studied intensively. Gingival and periodontal diseases, in their various forms, have afflicted mankind since the dawn of history. Diseases of the periodontium occur in childhood, adolescence, and early adulthood but the prevalence of periodontal disease, tissue destruction and tooth loss increases with age[20].

Apart from age, the factors such as immediate environment of the periodontium and systemic factors, resulting from the general condition of the patient are responsible for the periodontal disease.[4] Diabetes mellitus deserves a special consideration in any comprehensive text of periodontal diseases. Diabetes mellitus affects many people, as does periodontitis, and is found with increasing frequency as people get older as is periodontitis.[21,22]

The prevalence of diabetes mellitus is more than twice as high in patients with periodontitis compared to healthy subjects. Periodontal disease may contribute to systemic inflammation, worsening insulin resistance and diabetes due to the generation of inflammatory cytokines [23-25]

A large body of information exists, showing that prevention, early diagnosis and consequent treatment of periodontal disease may have a major impact on the control of diabetes. Severe periodontal disease causes attachment loss, alveolar bone loss and tooth loss, extending beyond the local level to produce systemic effects. It exacerbates the inflammatory milieu, increases insulin resistance, and potentially worsens cardiovascular disease. Severe periodontitis is a risk factor for early death due to ischemic heart disease or renal dysfunction independent of diabetes, increasing the risk 3.2 fold as compared with those with none, mild, or moderate periodontitis [10].

Periodontitis and its Effects on Diabetes

Periodontal diseases are bacteria-induced infections affecting the periodontium and resulting in the loss of tooth attachment. Porphyromonas gingivalis plays a central role in periodontal disease. P. gingivalis can invade endothelial cells and is a potent signal for monocyte and macrophage activation. Thus, once established in the tissue, this chronic infection complicates diabetes control and increases the occurrence and severity of microvascular and macrovascular complications. The presence of the periodontal pathogen bacteria thus increases the risk of stroke, ischemic heart disease and atherosclerosis [26].

Other relevant periodontal pathogen bacteria are: actinobacillusactinomycetemcomitans, treponemadenticola, fusobacterium nucleatum, prevotellaintermedia, eikenellacorrodens und camphylobacter rectus. These periodontal pathogen bacteria cause a chronic local lowgrade inflammation and contribute to systemic inflammation. This is reflected by higher circulating levels of inflammatory markers such as C-reactive protein, IL-6 and TNFα, the latter being responsible for worsening insulin resistance and diabetes [8]. Exacerbating immune reactions lead to self-destruction of periodontal tissue.

The increasing pocket depth and root surface infection, bacterial impact and invasion of periodontal tissue, alveolar bone loss and local and systemic immune reactions all have negative effects on diabetes. The association between diabetes and periodontal disease may be due to numerous physiological phenomena seen in diabetes, such as impaired (immune)

resistance, vascular changes, altered microflora, and abnormal collagen metabolism. This tends to support the higher incidence and severity of periodontitis in diabetic patients. The association between gene sets (for example IL1-genotype) and periodontitis has been discussed with conflicting conclusions [4,7].

There is a direct causal or modifying relationship in which poor glycemic control results in more severe periodontitis [4]. The worsening effects of diabetes on periodontal inflammation are well known. Studies also indicate a correlation between periodontal inflammation on diabetic balance and insulin resistance syndrome [3,6,8].This evidence points to a vicious cycle in which diabetes and periodontitis exacerbate one another. Periodontal treatment may improve diabetes control measured as a reduction in glycated hemoglobin [9]. Because of this relationship, the diabetes specialist should put an emphasis on oral health and its control as an integral part of diabetes treatment.

Diagnosis of periodontal diseease Diabetes is a disease that frequently causes multiple comorbidities. Periodontal disease and other oral pathologies (gingivitis, candidiasis, oral malignancies etc.) are frequent complications of diabetes. The diagnosis and control of periodontal disease with its adverse effects on insulin resistance through the generation of inflammatory cytokines can have a major impact on diabetes control and diagnosis.[31-34]

1. Basic diagnostic indices for periodontitis are: the evaluation of gingival bleeding and swelling, recessions, attachment loss, pathological pockets (depth >4mm), loss of tooth insertion, pocket exsudation, foetor, bleeding on probing with a special ball-point probe and alveolar bone loss assessed from radiographs.[27]

2. A further diagnostic step is the determination of inflammation markers such as sCRP, TNFα, IL-6, IL-10.

3. For diabetic patients, the identification of subgingival bacteria, especially p. gingivalis, p. intermedia, actinobacillusactinomycetemscomitans and t. forsythensis, represents another important diagnostic tool [35]. Consequent follow-up examinations should include a bacterial test to monitor subgingival bacterial levels which are best measured using a multiplex polymerase chain reaction. Very useful and simple tools are informational flyers to help increase patient awareness of periodontal disease, its association with diabetes and its prevention and treatment[28]

Pathologic Mechanisms

Periodontal disease is a chronic gram-negative infection thought to increase insulin resistance. Through this mechanism, it contributes as known, to the development of metabolic imbalance [41]. As multiple studies, recognize, the pathogenesis of periodontal disease is complex. It shows a combination of 2 processes: the initiation and maintenance of a chronic inflammatory process, developed with the help of a diverse microbial flora with its diversity of bacterial products. The host response to this infectious mechanism mediates a "cascade" of tissue destructive pathways [42]. Some time ago, researchers linked the role of microorganisms as being the main etiologic factor in PD. Nowadays this is not sufficient. The major component of periodontal tissue destruction is believed to be the result of the host immune-inflammatory response to bacterial challenge. Plaque biofilm and the associated host response are involved in PD pathogenesis [43].

Current Concepts and Future Considerations

Society evolution is commonly associated with the increased spread of diseases such as diabetes mellitus (DM) and periodontal disease (PD). DM and PD are known to be among the most prevalent human disorders and they are frequently and concurrently present in many people[30]

World Health Organization states in 2000, that there are nearly 177 million diabetic people worldwide and approximately 1 million in Romania. The same organization estimates an increase in the diabetic population of over 370 million worldwide and of 1.8 million in Romania, until 2030. It has been known for a long period of time, that periodontitis is a common chronic gram-negative anaerobic infectious disease. Other authors consider periodontitis as a chronic inflammatory disease characterized by connective tissue attachment loss and alveolar bone resorption which leads to tooth loss, by periodontal pocket formation[32].

Prevention of Periodontitis

The following behavioural recommendations should be included in regular instructions for diabetic patients:

1) No smoking

2) Strictglycemic control

3) Professional counseling on the importance of oral health (self-response, self-questionnaire)

4) Qualified instruction in home oral care and the importance of soft tooth brushes

5) Thorough oral cleaning at least twice a day – after breakfast and before bedtime – for more than 3 minutes

6) Daily interdental cleaning (floss, tooth picks, interdental-brushes)

7) Tongue-brushing

8) Proper tooth brush handling - daily disinfection of the tooth brush, drying, alternate use of two brushes, no natural bristles.

9) Partner treatment - if only one suffers from periodontitis special care should be taken to avoid transfer of bacteria through shared dishes, cups, forks; no kissing allowed during acute phases

10) Antibacterial and anti-inflammatory ingredients in toothpaste and mouth rinses, for example o chlorhexidine (anti-inflammatory), triclosan and thymol (anti-inflammatory)[29]

Periodontal Treatment of Diabetic Patients

1. Measurement of pocket depth using a ball-point probe

2. Extraction and identification of subgingival bacterial samples (paper points and sterile tubes, available from distributors or laboratories)

3. Germ reduction through the use of antibacterial mouthwash, pocket solutions, subgingival application of metronidazol gel, chlorhexidine gel (applied with mouth guards several times a week). The elimination of periodontal infection with these antibacterial adjuncts results in a reduction of the periodontal pathogen bacteria to low or even nondetectable levels.

4. A follow-up extraction and identification of subgingival bacteria samples (same extraction sites)

5. Scaling and/or root planing accompanied by antibiotic treatment

6. Maintenance of intensive oral care and additional use of mouthwash, controlled with regular PCR analysis

7. Recall[30]

Conclusion

Thus, the survey has shown positive results where periodontitis is an indicator for diabetes mellitus. The age distribution favourable for the condition is more than 50 years of age and the gender ratio is that females are more prone than males. For the diabetic status, awareness must be created among people to check their blood glucose level periodically.

The potential mechanistic interrelationships Periodontal treatment to control colonization of microbial pathogens and simultaneously reduce the level of pro inflammatory cytokines is also essential to prevent a worsening of diabetic conditions. Secondly, while proinflammatory cytokines, such as TNF-a and IL-1b, play key roles in this bidirectional relationship, it is also of interest to develop immunomodulators that target these cytokines. However, one must be cautious, because modulating these cytokines may also affect the body's homeostasis. In summary, an in-depth understanding of the possible mechanisms linking periodontal disease and diabetes, in terms of periodontal destruction and periodontal healing, is essential to the future development of treatment strategies for patients with diabetes and periodontal disease.

Abstract

Introduction: Enterococci have emerged as an important cause of nosocomial infection. Successful antibiotic treatment against enterococcal infection usually depends on the synergistic bactericidal effect achieved by the combination of a cell wall-active agent, such as ampicillin or amoxicillin, and amoxyclav. However, the prevalence of enterococci resistant to one or more of these antibiotics is increasing day by day which has resulted in serious therapeutic difficulties. The isolation of enterococcus and sensitivity pattern of the drugs was discussed. The aim of this study is to assess the incidence of Enterococcus species in post-operative local sepsis in the oral cavity.

Materials and Method: In this study 75 patients who reported to the dental outpatient department over the period of 6 months.The samples were processed in the microbiology lab according to the standard protocol and organisms were isolated and identified. After identification of the organisms, the antibiotic profile for each organism isolated was found by performing AST(Antibiotic Susceptibility testing) by Kirbybauer's method.

Result: Totally 75 samples were collected and processed out of which 37 samples showed positive bacterial culture. From these positive cultures 9 different species are isolated and enterococcus found to be in 15 samples. Comparing the sensitivity pattern for the most commonly prescribed antibiotics against Enterococcus species, we state that they are highly sensitive to amoxyclav followed by ampicillin and amoxicillin.

Conclusion: These three drugs amoxyclav, ampicillin and amoxicillin are commonly used in dentistry. According to this study only less than 50 % of the enterococcus isolates are found to be susceptible. It is also reported that the enterococcus sp were isolated in nearly 40 percentage of the failed cases in oral lesions.

***Key Words**: Enterococcus, antibioticsamoxicillin, ampicillin and amoxyclav.*

Introduction

Oral cavity contains more than 700 species of microorganisms as commensals. Some of them are considered as opportunistic pathogens which colonises the traumatised tissue in the oral cavity, it includes aerobes, facultative anaerobes and obligate anaerobes. Eradicating such organisms from the septic pockets was normally done by treating them with the drugs that cover aerobic and anaerobic organisms. Success of such treatments depends on the choice of drug and susceptibility in the organism. Dentist and physicians have endeavoured for years to device some effective measure for preventing bacteraemia since it was demonstrated that organisms invade the blood stream with greatease than previously realised [1]. Very few organisms in the oral flora exhibits resistance to the conventionally used antimicrobial agents. Among the oral flora Enterococcus shows multiple drug resistance and persist even after antibiotic therapy. Enterococcus is normally ignored by most of the practitioners in clinical samples as it is normal flora. Antimicrobial resistance is a major concern in a clinical set-up. Newer pathogens are evolving day by day which is a major threat in treating hospitalised patients [2].Although enterococci are generally considered as transient constituents of the oral micro-biome with a low colonization density, surprisingly little is known about their oral prevalence and incidence particularly in different population groups. Most of the currently available data pertain to the oral carriage of E. faecalis mainly in patients undergoing endodontic therapy, and it is considered as one of 25 most abundant pathogens causing persistent endodontic infections. On the contrary, patients with periodontitis or gingivitis exhibit an enterococcal prevalence ranging from 3.7 to 35%. Interestingly, it is reported that 60% of diabetic patients yielded oral Enterococcus faecalis, and E. faecium, as opposed to only 6.6% in the controls [3].In the human oral cavity, E. faecalis has been frequently detected from patients with post-treatment apical periodontitis or refractory marginal periodontitis. Isolates from oral infections differ from group of hospital-derived isolates, as

they do not present many mobile genetic elements. However, they usually carry virulence factors related to adhesion and biofilm formation, which may account for the colonization of different oral sites.

Furthermore, oral strains may also carry few antibiotic resistance determinants that have the potential to be transferred to other pathogenic bacteria in biofilm communities [4].Enterococcal surface protein (ESP) was highly associated with infection-derived isolates of E. faecium and E. faecalis. Studies have shown that ESP gene was detected in most strains isolated from endodontic and periodontal. As ESP has been associated to higher biofilm production of the strains, the high prevalence of ESP within oral isolates suggests that this surface protein may be a potential virulence trait that participates in colonization of different niches of the oral cavity [5].Enterococci are common inhabitants of the human intestinal micro-flora and the genitourinary tract of men and women [6]. Enterococci are also frequently present in most animals and common contaminants in food or used as starters in meat and cheese processing. Enterococci are potential pathogens in many body sites and enterococcal infections are often opportunistic and more prevalent in hospitalized patients [7]. The general interest for enterococci and treatment of enterococcal infections has increased due to the appearance of antibiotic multi-resistant strains and especially to the occurrence of vancomycin-resistant strains (vancomycin-resistant enterococci VRE)[8].Furthermore bacterial organisms, oral microorganisms can include fungal, viral and protozoal infections. The bacteria include hundreds of types of organisms of which only predominant ones have been identified[8, 9]. A variety of organisms in the micro flora of the oral cavity adhere to the teeth, the buccal mucosa, the tongue, and the gingival sulcus. Each site has a unique way of allowing the organisms to initiate their residency. The normal flora in healthy individuals maintains similar patterns. When a local or systemic disease process or concomitant use of medications alters this overall pattern, atypical organisms begin to predominate and some normal organisms with a benign nature, such as Candida albicans, become pathogenic.

The micro flora of the oral cavity changes with the age, the eruption or loss of teeth, and the appearance of disease states (e.g., caries, periodontal disease). Systemic changes, such as pregnancy or drug intake, also alter the number and proportion of flora. These changes are due to alterations in the flow and composition of salivary fluid and in the levels and activity of defence components (e.g., immunoglobulin, cytokines) in the saliva [7, 8].Besides the

microbiological methods, the divergence of the findings regarding the prevalence of E. faecalis in root canal infections may be also dependent on the patient selection. Usually, studies that have included only restored teeth have shown lower prevalence of E. faecalis in root-filled canals than those that have also included non-restored teeth, considering the same detection method. Therefore, the presence of coronal leakage by defective coronal restorations, old temporary restorative materials, or non-restored teeth may have influenced the microbial findings of the latter studies. These findings support the hypothesis that E. faecalis may enter the root-filled canal via coronal leakage during or after root-canal treatment as secondary invaders. However, as many studies did not mention the quality of restoration, it is not possible to determine whether E. faecalis positive samples resulted from its persistence to prior root-canal treatment (persistent infections) or were originated after root-canal treatment from invading E. faecalis into the root-filling, via coronal leakage (secondary infections). This study is done to evaluate the association of Enterococcus species in postoperative cases in dentistry[3,8]. This study also includes the evaluation of the sensitivity pattern of the Enterococcus isolates against the conventionally used anti-microbial agents used for chemoprophylaxis and treatment.

Materials and Methods

Samples are collected from 75 patients who reported to the dental outpatient department over the period of 6 months. The patients selected for the study are those who have underwent extraction or surgical therapy and have developed local sepsis post operation. Two types of sample were collected depending upon the type of lesion. Swabs were collected from superficial lesions and sub mucosal areas. Aspirates were done for deeper lesions that forms abscess. The samples were collected aseptically using sterile techniques by moistening them with sterile normal saline and from deep seeded lesion, needle aspirations were done, and thenthe samples were immediately transported to the microbiology lab for processing. The Samples were collected before administration of antibiotics. The patients were informed about the study conducted and informed concern was obtained.

The samples were processed in the microbiology lab according to the standard protocol. In this study the aerobes and the facultative anaerobes were analysed by performing routine bacterial culture. Three media were used for isolation and identification of the organisms they

are,Nutrient agar, MacConkey agar and blood agar. The samples were inoculated in all the three media and incubated at 37°C for 24 hours aerobically. After incubation the plates were checked for the bacterial growth and the organisms were identifiedby biochemical reactions and other tests as per the standard protocols. After identification of the organisms, the antibiotic profile for each organism isolated was found by performing AST (Antibiotic Susceptibility Testing) by Kirbybauer's method.

Results

Total no of samples processed: 75

No of samples positive for bacterial culture: 37(Fig: 1)

Totally 9 different species of bacteria are isolated from the bacterial culture. (Table: I)

Enterococcus sp were isolated from 38% of the samples in aerobic bacterial culture.(Fig:2).

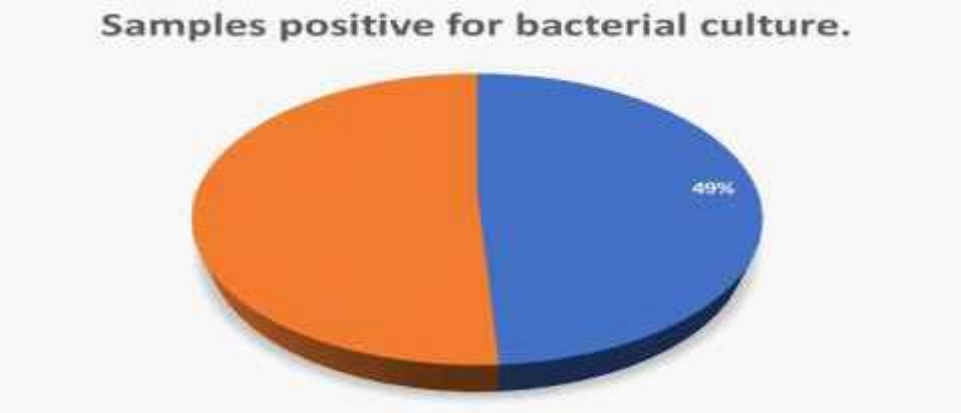

Figure 1: Pie chart showing the percentage of samples that are positive for bacterial culture out of the total no of samples processed.

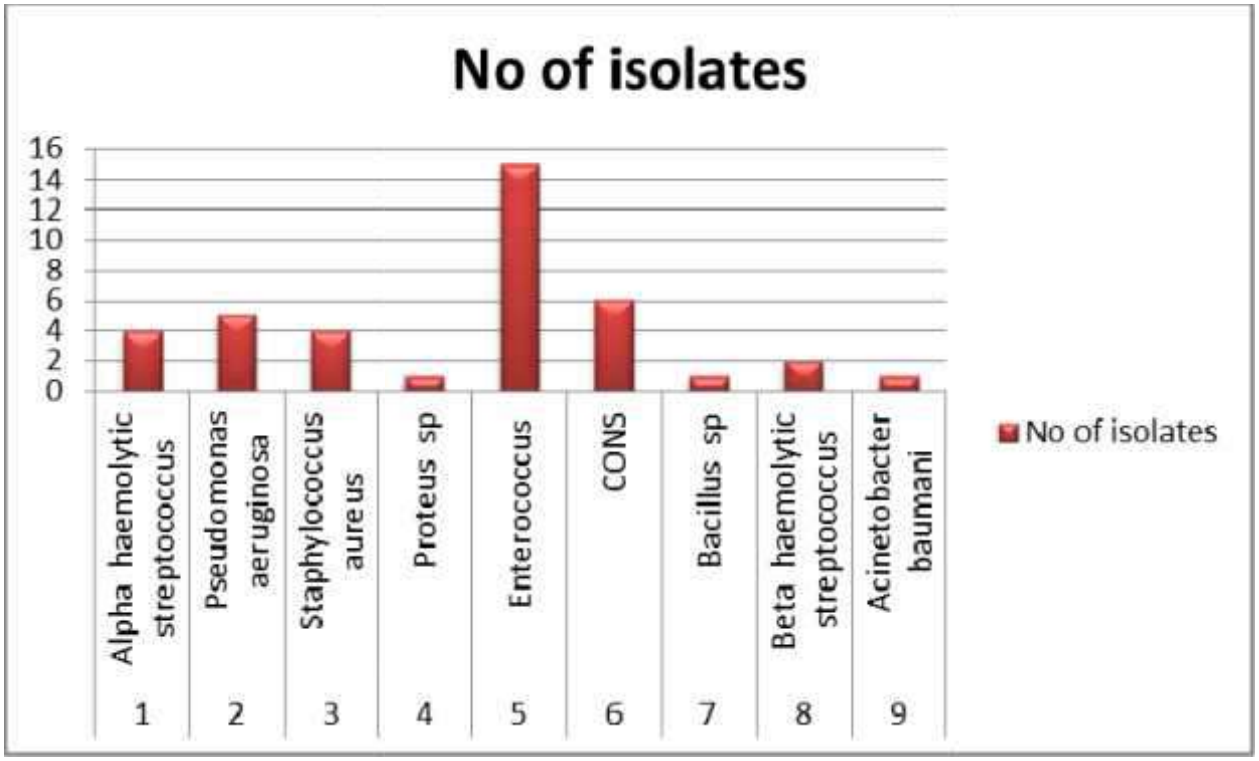
Table-1: Table shows the different species of organisms isolated along with the number of isolate.

Sl.no	Organisms isolated	No of isolates
1	Alpha haemolytic streptococcus	4
2	Pseudomonas aeruginosa	5
3	Staphylococcus aureus	4
4	Proteus sp	1
5	Enterococcus	15
6	CONS	6
7	Bacillus sp	1
8	Beta haemolytic streptococcus	2
9	Acinetobacterbaumani	1



Graph 1: The bar diagram shows relative properties of bacteria isolated.

Discussion

In this study, 75 samples were collected out of which 37 samples showed positive for the microbial growth. Totally 9 different species were isolated from the samples out of which Enterococcus isolated in 38%of the samples. Enterococci are considered as resident component of the oral microbiome that may cause a variety of oral and systemic infections so we are concerned with the isolation and sensitivity pattern of enterococcus species from the post-operative complications in the oral cavity[9].

Bacteria in the mouth may trigger a rare, life-threatening heart infection called infective endocarditis. Enterococcus faecalis infective endocarditis was a disease of utmostimportance, with more infected patients, increasing frequency of health-care associated infections and increasing incidence of antimicrobial resistences3. Enterococcal meningitis is another deadly caused by Enterococcus faecalis and Enterococcus faecium disease with high mortality rate [10].

In the last few decades, the percentage of older adult Polish citizens with decreased masticatory function significantly increased. Relatively high prevalence of oral trichomonads and E. gingivalis in the present study, and, also the detection of Acanthamoeba spp. cysts in older adult patients, are in agreement with several previous findings. Various strains of Acanthamoeba sp. are worldwide amphizoic amoebae that may cause serious human health threats as etiological agents of granulomatous amoebic encephalitis and vision-threatening Acanthamoeba keratitis. The amoebae were isolated from the hospital environment, among others, as contaminants of surgical instruments and the dental irrigation system. It was considered that ontogenetic-depending factors influence the oral protozoans that are agents predisposing to local inflammations and a real threat of disseminated infections[8, 9, 11].

Enterococci are generally considered as transient oral bacteria. However, their prevalence in various population groups has not been fully evaluated, with only sparse data mainly from North American and European studies[11]. To our knowledge, this is the first study to report the prevalence of oral enterococci from a South American cohort belonging to a spectrum of age groups. As we intended to study a sample representative of the general population the

exclusion criteria included only the most frequently reported conditions that affect the oral microbiome such as, diabetes, pregnancy, wearing orthodontic appliances and dentures, use of mouth rinses, and medications that affected the salivary flow[12].

It is emphasized in literature that, in generally healthy persons, complex interrelations occur between multilayer components of biofilm, particular species of oral micro biota, and the host organism. This results in relatively constant composition of the oral cavity micro biome because the human immunological system influences the oral environment stability by some inhibition of multiplication activity of micro biota, which remains in labile homeostasis. Many biotic and abiotic factors that can alter this homeostasis may influence the multispecies microbial communities and increase the number of certain endogenous bacteria. This can also lead to a colonization of the oral cavity by exogenous species, including those that are potentially pathogenic.

Medicinal use of guava has been demonstrated in various scenarios. The important constituents of guava are vitamins, tannins, phenolic compounds, flavonoids, etc. The two important flavonoids quercetin are known for their antimicrobial and anti-oxidant effect. Guaijaverin inhibits the growth of streptococcus mutants as it increases hydrophobicity which an important factor for the oral pathogens to adhere to the tooth [13].This inhibits plaque deposit and inhibits the growth of microorganisms without disrupting the homeostatis of the oral cavity. Quercetin on the other hand disrupts the cell membrane, inactivates the extracellular proteins and form irreversible products. These prove to be bacteriostatic. It also contains vitamin c which improves healing property[14].

Deep enterococcal infections in the jaws (abscesses, bone sequestration and open surgical wounds) do occur and should be considered in the choice of antibiotics. All 18 cases were on antimicrobial treatment and 10 of them were on clindamycin, a drug that is not suitable for enterococcal infections. Unfortunately, clindamycin prescription by dentists is increasing, probably due to overuse or recommendations to use clindamycin in penicillin allergy cases[15]. The frequent occurrence of enterococcal infections in the oral cavity points to the importance for an appropriate microbiological diagnosis and susceptibility test in cases of need for antibiotic treatment [16].

At present, the guidelines published by the Infectious Diseases Society of America, the World Society of Emergency Surgery, and the Tokyo consensus meeting all recommend

treatment withsulbactam or amoxicillin plus clavulanic acid after cholecystectomy for non-complicated acute calculuscholecystitis. In the present series, we did not observe a benefit of postoperative antibiotic treatment on infections for patients with grade I or II acute calculuscholecystitis [14, 15, and 16].

Macrolides are also alternative regimens recommended for dental procedures when patients are allergic to penicillin. However, erythromycin seems to be of limited value against oral enterococci. Recently, Rams. Having shown that only 19% of periodontal E. faecalis clinical isolates were susceptible to erythromycin and most of the isolates (55%) showed an intermediate pattern. These findings are similar to previous evaluations of endodontic E. faecalis strains[17]. Moreover, the genetic determinant of macrolide resistance (ermB) has been detected in approximately 60% of endodontic E. faecalis isolates[18].

Tetracyclines are broad-spectrum antibiotics, but bacterial resistance has reduced their clinical usefulness in oral infections. This antibiotic has exerted poor in vitro activity against periodontal E. faecalis; tetracycline resistance was detected in over 50% of the E. faecalis periodontal isolates [19]. Moreover, a high prevalence of the genetic determinant of tetracycline resistance (tetM) has been recently detected in endodontic isolates [16]. Interestingly, in the latter study, approximately 50% isolates of endodontic origin carried both the ermB and tetM genes. The occurrence of multiple resistances to erythromycin and tetracycline is probably associated with the presence of conjugative transposons Tn916 family-Tn545, which carriesermB and tetM genes. It has been suggested that this mobile genetic element may have contributed to the dissemination of erythromycin and tetracycline resistance within the oral micro biota[20].

The drug of choice for most of the antibiotic prophylaxis in dentistry is amoxicillin, ampicillin and amoxyclav. Sensitivity pattern for the above mentioned drugs were tested and tabulated below.

Comparing the sensitivity pattern for the most commonly prescribed antibiotics against Enterococcus species, we state that the 3 antibiotics evaluated belong to beta-lactam group and are widely and commonly used by dentist in outpatient clinics. They show a similar susceptibility pattern 46.6 % with the enterococcus isolates. (Table: II)

Table- 2: Table showing the susceptibility pattern of Enterococcus species against the three drugs tested

Sl.no	ANTIBIOTIC	No. of isolates	No. susceptible	Percentage susceptible
1	Amoxyclav	15	7	46.6
2	Ampicillin	15	7	46.6
3	Amoxycillin	15	7	46.6

Conclusion

These three drugs amoxyclav, ampicillin and amoxicillin are commonly used in dentistry. According to this study only less than 50 % of the enterococcus isolates are found to be susceptible. It is also reported that the enterococcus sp were isolated in nearly 40 percentage of the failed cases in oral lesions. It is time to consider the other options for chemoprophylaxis in dental treatments. Isolation of enterococci resistant to multiple antibiotics has become increasingly common in the hospital setting5. This cannot be the drug of choice in elderly patients and patient having other underlying medical problems. Linezolid is also tested for all gram positive bacteria isolated from clinical samples which have shown high sensitivity, so this can be considered as an alternative for the patient underwent major surgery. The next drug which has a beneficial effect is ciproflaxin this can be given as an antibiotic cover for pre and post-surgical prophylaxis and for the outpatient procedures. According to National Nosocomial Infections Surveillance (NNIS) data from January 2003 through December 2003, more than 28% of Enterococcal isolates in ICUs of the more than 300 participating hospitals were vancomycin-resistant. Clonal spread is the dominant factor in the dissemination of multiple drug-resistant enterococci in North America and Europe. Virulence and pathogenicity factors have been described using molecular techniques. Several genes isolated from resistant enterococci encode virulence factors such as the production of gelatinase and haemolysin, adherence to caco-2 and hep-2 cells, and capacity for biofilm formation. The choice of antibiotics plays a very important role in fighting against micro-organisms; this can be achieved by checking the sensitivity pattern of drug against them.

Abstract

Introduction: Halitosis has multiple etiology though physiological factors plays a major role.Presence of lactobacilli is considered as one of the reason for halitosis.When the salivary PH is altered,it facilitates the growth of lactobacilli.Halitosis is not a disease,it's a discomfort in the oral cavity.Dental caries also causes halitosis .If the number of this bacteria in the mouth is reduced,halitosis in the oral cavity can be prevented.This study is conducted to estimate the contribution and association of lactobacilli in halitosis.

Materials and Methods: Lactobacilli association with caries is already proved and its contribution in halitosis cases is estimated in this study. It is done by examining the lactobacilli load of patients with halitosis and dental caries.The saliva sample of bad breadth and widespread caries is collected in a sterile container.And 10 microlitre is transferred to the lactobacilli agar and its being incubated. Afterincubation, the number of colonies is demonstrated and counted.

Results: The lactobacilli count obtained ranges from 500 colonies/ml to 6800colonies/ml.65% of the samples had shown the colony count of more than 3000/ml and 35% of the samples had shown the colony count of less than 3000/ml.There is a considerable increase in many cases.This is definitely higher than the bacilli count in normal healthy oral cavity. In normal healthy oral cavity lactobacilli count is less than 1000/ml.

Conclusion: This indicates the Lactobacilli is not solely responsible for caries activity but it precipitates the problem. It is believed that extensive caries lesion in mouth is the reason for

bad breadth. This study shows there is a considerable increase in Lactobacilli count in carious individuals which contributes to halitosis and they are not responsible for initiation of caries.

***Key Words**: halitosis,odour,lactobacilli,breadth,discomfort*.

Introduction

Halitosis, also commonly known as “bad breath,” is a concern of many patients seeking help from health care professionals. The health care workers have neglected the subject of oral malodour but recently, along with the growing public and media interest in oral malodour; health care professionals are becoming more aware of their patient’s concern. A patient with halitosis is most likely to contact primary care practitioner for the diagnosis and management. Most physicians and dental practitioners are inadequately informed about the causes and treatments of halitosis. The present article succinctly focuses on the development of a systematic flow of events to come to the best management of the halitosis from the primary care practitioner’s point of view. The epidemiological research on halitosis is inadequate since it is still a considerable but underrated taboo.Oral malodour is a problem that afflicts large population.Because halitosis can connect or disconnect an individual from the social environment. It plays an important role in self-image and social interactions. Halitosis affects people with varying degrees of intensity. The most common oral malodour products are by products of metabolism of certain species of oral bacteria present in saliva, plaque and gingival crevicular fluid .Halitosis is mainly seen in diabetic patients and patients with caries.Lactobacilli,a gram positive bacteria is usually benign except in the mouth where they have been associated with cavities and tooth decay.[1]Studies have proven that lactobacillus count in saliva has been used as caries test for many years[2,3].Recent studies have also proven that lactobacilli is seen in caries and halitosis patients.[4]The reasons for the lack of scientific data are the difference in cultural and racial appreciation of odours for patients and investigators, and there is the absence of uniformity in evaluation methods, as for organoleptical as for mechanical measurements. Moreover, there are no universally accepted standard criteria, objective or subjective, that define a halitosis patient. There are few studies documenting the prevalence of halitosis in population wide or community based samples. In the general population, halitosis has a prevalence ranging from 50% in the USA to between 6% and 23% in china, and a recent study had revealed a prevalence ofself reported halitosis

among Indian dental students ranging from 21.7% in males to 35.3% in females.[7,8,12] Miyazaki concluded that there was increased correlation between older age and malodour with aging resulting in greater intensity the of odour. In above 60 years age group of the Turkish individuals, the incidence was around 28%.A thorough literature search reveals a lack of studies on halitosis in India, especially among the general population.

Etiology of Halitosis

It is imperative to understand the origin of halitosis as multidisciplinary therapy typically is required in halitosis with emphasis on the causative factor. Halitosis can be broadly classified on the basis of its origin as Genuine Halitosis and Delusional Halitosis .Physiological halitosis (foul morning breath, morning halitosis) is caused by stagnation of saliva and putrefaction of entrapped food particles and desquamated epithelial cells by the accumulation of bacteria on the dorsum of the tongue, recognized clinically as coated tongue and decrease in frequent liquid intake.[13,14,15]Intraoral conditions are the cause of 80–85% of halitosis cases.Periodontal infections are characterized by a tremendous increase in Gram-negative bacteria that produce volatile sulphur compounds (VSCs). The association between anaerobic bacteria that produces VSCs and halitosis has been well-documented.Most important VSCs are hydrogen sulphide (H2 S), methyl mercaptan and dimethyl sulfide.The dorsum of the tongue is the biggest reservoir of bacteria as a source of malodorous gases. Pericoronitis, oral ulcers, periodontal abscess, and herpetic gingivitis are some of the pathologies that result in increased VSCs. Diamines such as putrescine and cadaverine are also responsible for oral malodor as with the increase in periodontal pocket depth; oxygen tension decreases which results in low pH necessary for the activation of the decarboxylation of amino acids to malodorous diamines.[16,17]Odontogenic infections include retention of food debris in deep carious lesions and large interdental areas, maligned teeth, faulty restorations, exposed necrotic pulp, over wearing of acrylic dentures at night, wound infection at the extraction site and ill-fitting prosthesis. The absence of saliva or hypo function results in an increased Gram-negative microbial load, which increases VSCs, a known cause of malodour. Several mucosal lesions such as syphilis, tuberculosis, stomatitis, intraoral neoplasia and peri-implantitis allow colonization of microorganisms that releases a large amount of malodors compounds.[18]

Materials and Methods

Lactobacilli association with caries is already proved andits contribution in halitosis cases is estimated in this study.The saliva sample of bad breadth and widespread caries is collected in a sterile container.Transfer 10 microlitre to the lactobacilli agar and its being incubated.Afterincubation,the number of colonies is demonstrated and counted.Results are expressed as colony forming units per 100 millilitre in the table below.

Results

SL.NO	LACTOBACILLI COUNT/ ml
1	500
2	500
3	900
4	1000
5	1200
6	1900

16	5000
17	5200
18	5500
19	6000
20	6800

In this study to know about the association between halitosis and amount of lactobacilli present in the saliva.The samples were inoculated into lactobacilli selective media.After incubation lactobacilli count was done.The lactobacilli count obtained ranges from 500 colonies/ml to 6800colonies/ml.65% of the samples had shown the colony count of more than 3000/ml and 35% of the samples had shown the colony count of less than 3000/ml.There is a considerable increase in many cases.This is definitely higher than the bacilli count in normal healthy oral cavity. In normal healthy oral cavity lactobacilli count is less than 1000/ml. In this study there is no direct correlation between Lactobacilli load ,saliva and caries activity.All the patients selected for the study have multiple carious lesion but Lactobacilli count in saliva ranges from 500 per ml to 6800 per ml.This indicates the Lactobacilli is not solely responsible for caries activity but it precipitates the problem.It is believed that extensive caries lesion in mouth is the reason for bad breadth.This study shows there is a considerable increase in Lactobacilli count in carious individuals which contributes to halitosis and they are not responsible for initiation of caries.

Discussion

Lactobacillus is associated with progression of caries which actively damage pulpal tissues of teeth.Increase in presence of Lactobacilli in saliva is directly associated with caries activity.Though Lactobacilli is not initiating caries formation initially,in a patient who has caries activity the presence of Lactobacilli is very important.Presence of Lactobacilli in mouth is associated with alteration in pH of the saliva.There are common findings seen in gastric and peptic ulcer.Eradication of halitosis must be considered first.Mechanical removal of biofilm and microorganisms is the first step in the control of halitosis. A systemic review by van derSleen et al. demonstrated that tongue brushing or tongue scraping have the potential to successfully reduce breath odour and tongue coating.Tongue scrapers are shaped according to the anatomy of the tongue and reduces 75% VSCs compared to only 45% using a toothbrush. Antibacterial mouth rinsing agents include chlorhexidine (CHX), cetylpyridinium chloride (CPC) and triclosan, which act on halitosis-producing bacteria. A systematic review, published by Cochrane, compared the effectiveness of mouth rinses in controlling halitosis.The researchers concluded that mouth rinses containing CHX and CPC

could inhibit production of VSCs while mouth rinses containing chlorine dioxide and zinc may neutralize the sulphur compounds producing halitosis. CHX is considered as the gold standard mouth rinse for halitosis treatment. CHX in combination with CPC produce greater fall in VSCs level, and both aerobic and anaerobic bacterial counts showed the lowest percentage of survival in a randomized, double–blind, cross–over study design. The usage of masking agents like rinsing products, sprays, toothpaste containing fluorides, mint tablets or chewing gum only have a short-term masking effect.[19,20]When treating patients with oral malodour, clinicians should relate not only to physiological odour and associated parameters but also to the nature of the subjective complaint. In halitosis management, a well-established understanding between a patient and a primary healthcare clinician can bring a successful result. A primary healthcare clinician must exhibit attitudes of acceptance, sympathy, support, and reassurance to reduce the patient's anxiety. Professionals can improve patient quality of life as a whole, improving their social interactions and relationships. A sustained encouragement and reassurance need to be given by the patient's primary healthcare clinician, family, and friends. Due to the multifactorial complexity of halitosis, patients should be treated individually, rather than be categorized.Diagnosis and treatment need to be a multidisciplinary approach involving the primary healthcare clinician, dentist, an ENT specialist, nutritionist, gastroenterologist and clinical psychologist.Future research is needed to test accessible methods of drawing a person's attention to his/her halitosis, being the first step of seeking treatment. [24,25,26]

Conclusion

Halitosis is an extremely unappealing characteristic of sociocultural interactions and may have long-term detrimental aftereffects on psychosocial relationships. With proper diagnosis, identification of the etiology, and timely referrals when needed, steps can be taken to create a successful individualized therapeutic approach for each patient seeking assistance. It is significant to highlight the necessity of an interdisciplinary method for the treatment of halitosis to prevent misdiagnosis or unnecessary treatment. The literature on halitosis, especially with randomized clinical trials, is scarce and additional studies are required. This indicates the Lactobacilli is not solely responsible for caries activity but it precipitates the problem.It is believed that extensive caries lesion in mouth is the reason for bad

breadth.[21,22]This study shows there is a considerable increase in Lactobacilli count in carious individuals which contributes to halitosis and they are not responsible for initiation of caries.[23]

Abstract

Introduction: Thyroid hormones influence all major metabolic pathways. SH stimulates the thyroid gland to make thyroid hormones and secrete them into the blood. The thyroid hormones control the body's metabolism and can affect cholesterol levels. When thyroid hormone levels are low and TSH levels are increased, cholesterol levels are increased.Their most obvious and well-known action is an increase in basal energy expenditure obtained acting on protein, carbohydrate and lipid metabolism. With specific regard to lipid metabolism, thyroid hormones affect synthesis, mobilisation and degradation of lipids, although degradation is influenced more than synthesis.The main and best-known effects on lipid metabolism include: (a) enhanced utilisation of lipid substrates; (b) increase in the synthesis and mobilisation of triglycerides stored in adipose tissue; (c) increase in the concentration of non-esterified fatty acids (NEFA); and (d) increase of lipoprotein-lipase activity. While severe hypothyroidism is usually associated with an increased serum concentration of total cholesterol and atherogenic lipoproteins, the occurrence of acute myocardial infarction (AMI) in hypothyroid patients is not frequent.The aim of the study is to assess the prevalence of lipid abnormalities in thyroid patients.To assess the prevalence of lipid abnormalities in thyroid patients. The Study of lipid profile was conducted in 50 thyroid patients.

Materials and Method: Cross sectional study demonstrating the lipid abnormalities in 50 thyroid patients in Saveetha medical college. Data was collected using a pro forma which consists of clinical profile,lipid profile and thyroid profile. Values were estimated and statistics was done.

Result: Total cholesterol and LDL cholesterol were found to maintain significant positive correlation with serum TSH. But TSH was found to show no correlation with serum HDL cholesterol and serum triglycerides level. Significant negative correlation of FT4 with

triglycerides level and no correlation of TSH with triglycerides appear to make a sense of functional disharmony between FT4 and TSH and, therefore, a large scale study is recommended to make it clear.

Conclusion: Results of our study suggest the findings of dyslipidemia in hypothyroid patients. Therefore, patients presenting with dyslipidemia are recommended to be investigated for hypothyroidism. As our sample size was small and duration of study was limited, another study with large sample size and longer duration is also recommended

Introduction

Hypothyroidism is a clinical syndrome resulting from a deficiency of thyroid hormones, which in turn results in a generalized slowing down of metabolic processes[1]. It is a common metabolic disorder in general population[2]. The thyroid dysfunction increases with age, especially in women[3]. Hypothyroidism is associated with many biochemical abnormalities. Levels of total cholesterol and low density lipoprotein cholesterol tend to increase as thyroid functiondeclines[2]. Thus hypothyroidism constitutes a significant cause of secondary dyslipidaemia [4]. In hypothyroid patients, despite the reduced activity of HMG CoA reductase, there is often an increase in the serum total cholesterol concentration, mainly due to raised levels of serum LDL cholesterol and intermediate density lipoprotein (IDL) cholesterol[5]. Decreased thyroid secretion greatly increases the plasma concentration of cholesterol because of decreased rate of cholesterol secretion in the bile and consequent diminished loss in the faeces due to decreased number of low density lipoprotein receptors on liver cells[6]. Decreased activity of LDL receptors resulting in decreased receptor-mediated catabolism of LDL and IDL is the main cause of the hypercholesterolemia observed in hypothyroidism[7]. Serum concentration of high density lipoprotein cholesterol was reported to be higher among newly diagnosed hypothyroid patients with the value more than 40 mg/dL in subclinical or clinical hypothyroidism whereas serum concentrations of HDL cholesterol were significantly lower among euthyroid and previously reported hypothyroid cases who were on thyroid replacement therapy[8]. Hypothyroid patients usually exhibit elevated levels of high density lipoprotein cholesterol (HDL-C) mainly due to increased concentration of HDL particles[9]. In some studies we find confronting results regarding high density lipoprotein cholesterol levels in hypothyroidism. In thyroidectomized rats there was 25.9%

decrease in HDL-C level, suggesting a defect in HDL metabolism [10]. HDL cholesterol level was found reduced in some other studies on hypothyroid patients[9]. Decreased thyroid secretion greatly increases the plasma concentration of triglycerides[6]. Nikkilia & Kekki11 have stated that hypertriglyceridemia in hypothyroidism is due to decreased activity of lipoprotein lipase (LPL), which results in decreased clearance of triglyceride-rich lipoproteins. Dyslipidemia is a well-known risk factor for cardiovascular diseases. The risk of coronary heart disease and other forms of atherosclerotic vascular disease rises with rising plasma cholesterol concentration and in particular with rising ratio of total cholesterol to high density lipoprotein (HDL) cholesterol. A weak positive correlation of coronary heart disease also exists with plasma triglyceride concentration[12]. Early diagnosis and proper management can significantly reduce the mortality and morbidity of dyslipidaemia cardiovascular diseases. Extensive large-scale randomised trials have shown that lowering total cholesterol and LDL cholesterol reduces the risk of cardiovascular events like angina, myocardial infarction and stroke, and also reduces the need for revascularization [12].

Many studies were done to assess the lipid profile status of hypothyroid patients. But controversies still prevail and that needs to attain consensus. So, we have designed this study in our population for evaluation of lipid profile in hypothyroid patients that might be helpful for clinical management of hypothyroid patients with dyslipidaemia.

The aim of the study is to assess the prevalence of lipid abnormalities in thyroid patients.

Materials and Methods

This cross sectional study was conducted in the department of General medicine of Saveetha Medical University, Chennault to evaluate the lipid profile of hypothyroid patients and to find out relationship of Dyslipidemia with severity of hypothyroidism. Clinically of both sexes.Hypothyroidism was diagnosed by clinical history, physical examinations and relevant laboratory investigations. Total 50 subjects were included in the study and out of them 11 overt hypothyroid patients were grouped as cases (Group I) and 9 euthyroid subjects were grouped as normal controls (Group II). Cases were further grouped on the basis of their serum TSH concentration into Group A (TSH level 5.01-50.00 mIU/L), Group B (TSH 50.00100.00 mIU/L) and Group C (TSH level>100.00 mIU/L).

Statistical Analysis

Statistical analyses were performed by using SPSS for Windows version 12.0. Mean values of the findings were compared among and between groups. Analysis of variance (ANOVA)

test and Unpaired 't' test were done to assess the significance among the groups and between groups respectively. Pearson correlation coefficient test was done to evaluate the correlation of biochemical parameters with the severity of hypothyroidism. 'p' values <0.05 were considered significant.

Results

Table I shows the comparison of the lipid profile parameters between the cases and the controls. Mean total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides level in cases were higher than controls. HDL cholesterol was found significantly decreased in cases compared to controls. Table II shows lipid profile parameters in different groups of cases. There was no significant difference among the groups for serum total cholesterol, but a rising trend was found from Group A to Group C. For HDL cholesterol levels, significant differences were observed among the groups with maximum in Group B and minimum in Group C. Mean LDL cholesterol levels showed significant difference among the groups with maximum in Group C and minimum in Group A. Mean serum triglyceride levels showed no significant difference among groups.

Table 1: Lipid Profile of Study Subject

Parameters	Cases (n= 80)	Cases (n= 80)	Cases (n= 80)
Total cholesterol (mg/dL)	241.56 ± 60.05	146.94 ± 23.21	< 0.001
HDL cholesterol (mg/dL)	49.59 ± 11.69	55.89 ± 11.70	< 0.05
LDL cholesterol (mg/dL)	151.96 ± 59.60	71.43 ± 26.83	< 0.001
Triglycerides (mg/dL)	212.28 ± 100.73	98.87 ± 39.69	< 0.001

Table 2: Lipid Profile in Different Groups of Case

Parameters	Group A	Group B	Group C	'P'values
Total cholesterol (mg/dL)	215.93 ± 43.25	237.10 ± 64.49	254.76 ± 59.61	> 0.05

HDL cholesterol (mg/dL)	51.36 ± 9.84	53.34 ± 13.01	45.97 ± 10.35	< 0.05
LDL cholesterol (mg/dL)	119.64 ± 45.00	150.41 ± 61.28	165.41 ± 59.57	< 0.05
Triglycerides (mg/dL)	224.36 ± 88.83	221.16 ± 112.39	221.16 ± 112.39	> 0.05

Discussion

Hypothyroidism is a common metabolic disorder. The prevalence of primary hypothyroidism is 1:100, but it maybe 5:100 if patients with subclinical hypothyroidism (normal T4, raised TSH) are included [13]. According to a study done by Sawin [14], hypothyroidism is a common disorder with a prevalence rate up to 20%. In another cross-sectional study on twelve hundred and twelve subjects of both sexes and age 20-60 years, the incidence of subclinical hypothyroidism was 19.7% [15]. In our study, mean total cholesterol, LDL cholesterol and triglycerides were found significantly increased whereas HDL cholesterol was found significantly decreased in cases compared to controls. Jung [16] found mean plasma total cholesterol and LDL cholesterol levels elevated in hypothyroid cases than in normal controls. In another study, average serum total cholesterol level was found elevated in primary and secondary hypothyroidism [17]. Keyes &Heimberg18, Laker & Mayes [19] found triglyceride level elevated in hypothyroid patients. So, our study findings were consistent with the previous studies done by other investigators. Thompson [7] and Abrams & Grundy [20] have stated decreased activity of LDL receptors as the main cause of hypercholesterolemia in hypothyroidism. Serum concentrations of high density lipoprotein cholesterol was reported to be higher among newly diagnosed hypothyroid patients (subclinical or clinical) whereas serum concentrations of HDL cholesterol were significantly lower among euthyroid and previously reported hypothyroid cases who were on thyroxine replacement therapy [8]. Studies done by Michalopoulou [21], Diekman [22], Tsmihodimos [23] and Olukoga [24] showed average serum concentration of HDL higher in subclinical or clinical hypothyroidism. But, on the other hand, in a study on thyroidectomized rats, HDL-C showed a 25.9% decrease compared to controls [10]. In another study on thyroidectomized rats, there was 25% decrease in HDL cholesterol level compared to control rats [25]. Abrams & Grundy 20 have shown in their studies reduction of HDL cholesterol in hypothyroidism. So, our study is consistent with some of the studies and inconsistent with the others. A large

scale study on overt hypothyroid patients is recommended to come to a final conclusion. Increase in HDL cholesterol concentration is mainly due to increased concentration of HDL particles. Dullaart [26] have stated that decreased activity of CETP (cholesteryl ester transport protein) results in reduced transfer of cholesteryl esters from HDL to VLDL, thus increasing HDL cholesterol levels. Lam [27] have stated that in hypothyroid patients decreased activity of hepatic lipase leads to the decreased catabolism of HDL particles leading to increased HDL. So, decrease in HDL cholesterol level in our study might be due to increased activity of CETP and lipoprotein lipase in hypothyroid patients. There was no significant difference in serum total cholesterol concentrations among the groups, but a rising trend was found from Group A to Group C ($p = 0.0395$),making our results apparently consistent with the severity of hypothyroidism. This theme seems to be further consolidated by increasing LDL concentrations in line with the increasing severity of hypothyroidism from Group A to Group C as revealed in our study. This is further strengthened by our findings of negative correlation of FT4 and positive correlation of TSH with total cholesterol and LDL cholesterol levels. Significant difference in serum HDL cholesterol levels was observed among the groups with maximum in Group B and minimum in Group C. This finding partially indicates the lowest HDL with maximum degree of hypothyroidism. But the characteristic pattern of decreasing HDL with increasing severity of hypothyroidism could not be revealed in this study. This is further supported by our finding of no correlation of HDL with FT4 or TSH. This might be due to our small sample size. Regarding triglycerides levels, no significant difference was found among the groups, indicating no changing impact on triglycerides metabolism with severity of hypothyroidism. It is claimed that thyroid hormones facilitate the LPL activity11, but deficiency of thyroid hormones to inhibit LPL probably follows a ceiling point beyond which further reduction of thyroid hormones does not cause further inhibition of LPL. In our study FT4 has shown significant negative correlation with serum total cholesterol, LDL cholesterol and triglycerides level. No correlation was found between serum FT4 level and serum HDL cholesterol level. Total cholesterol and LDL cholesterol were found to maintain significant positive correlation with serum TSH. But TSH was found to show no correlation with serum HDL cholesterol and serum triglycerides level. Significant negative correlation of FT4 with triglycerides level and no correlation of TSH with triglycerides appear to make a sense of functional disharmony between FT4 and TSH and, therefore, a large scale study is recommended to make it clear. Results of our study suggest the findings of dyslipidemia in hypothyroid patients. Therefore, patients presenting with dyslipidemia are recommended to be investigated for

hypothyroidism. As our sample size was small and duration of study was limited, another study with large sample size and longer duration is also recommended.

Conclusion

Results of our study suggest the findings of dyslipidemia in hypothyroid patients. Therefore, patients representing with dyslipidemia are recommended to be investigated for hypothyroidism. As our sample size was small and duration of study was limited, another study with large sample size and longer duration is also recommended.

Abstract

Aim : The aim of the study is to evaluate a potential relationship between pterygoid plate symmetry and the occurrence of TMD by comparing LPP measurements.

Materials and Method : Fifty skulls were examined and the lateral pterygoid plate was measured with the help of a vernier caliper.

Result : The mean value of the left lateral pterygoid plate is 1.946 cm and the right lateral pterygoid plate is 1.969 cm. the difference between these two plates is +\-0.023cm.

Conclusion: The lateral pterygoid plate is thought to play an important in the control of jaw movements because of the presence of abnormal patterns of lateral pterygoid muscle activity in some TMD patients. The average value of the length of the LPP was measured in all instancesfrom the point of junction between lamina and the greater wing of sphenoid to the midpoint of the lower margin of the lamina. The lateral pterygoid muscle consists of a superior head and lower or inferior head. Classically, the inferior head is said to be active during jaw opening, jaw protrusion and contra lateral jaw movements and arises from the lateral surface of the LPP.

Keywords: *Lateral pterygoid plate, Skulls, Jaw movements, Muscle, Lamina*

Introduction

A broad thin plate that forms the lateral part of the pterygoid processes and gives attachment to the lateral pterygoid muscle on its lateral surface and to the medial pterygoid muscle on its medial surface, hence called as lateral pterygoid plate. It has two heads; superiorhead and inferior head.

Superior head is originated from the infra temporal crest of the greater wing of phenolic bone. The inferior head is originated from the lateral surface of lateral pterygoid plate. The two heads unite to form a strong tendon. They are inserted into the neck of the mandible, articulate disc of temporal mandibular joint (TMJ) and the capsule of the TMJ. They are supplied by the mandibular nerve where the nerve enters the deep surface of the muscle. Its action is to depress the mandible and draws the articulation disc forwards. It protracts the lower jaw. It is the opener of the jaw [1].

Its relations are; it is superficially related to the masseter muscle, maxillary artery and temporalismuscle. Its deep relations are sphenoid mandibular ligament, mandibular nerve, chorda tympani nerve and medial pterygoid muscle [2].Its upper border is related to deep temporal nerves, deep temporal vessels and nerve and artery to masseter. Its lower border is related to lingual nerve of inferior alveolar nerve, inferior alveolar artery, and sphenomandibular ligament.

Between the two heads the following structures are situated. Buccal branch of mandibular nerve, buccal branch of maxillary artery, pterygoid plexus of veins are found on the outer surface of the muscle, and the maxillary artery[3].

Temporomandibular disorder (TMD) is a general term that includes a series of clinical alterations involving the Temporomandibular joint (TMJ) and structures related to it, such as the masticatory muscles. These muscles are frequently related to TMD since they receive an overload, usually caused by parafunctional habits and occlusal disorders, so that clinical manifestation of this condition is translated into pain [4-7]. The lateral pterygoid muscle (LPM), one of the most important muscles in the physiology of mastication, is directly connected to the

TMJ and participates in the movements of opening, closing, laterality and mandibular protrusion. It is deeply localized to both the mandibular branch and temporal muscle, which makes its evaluation difficult [8]. Palpation of LPM is not possible owing to the topographic localization of its lower head. [9,10]. A small portion of the upper fibres of the LPM are inserted into both the articular capsule and articular disc of the TMJ, giving stability to the set and directly influencing articular disc position during mandibular movements [11,12]. MRI is a powerful tool for evaluation of changes in the articular structure and masticatory muscles,[13,14] but there are few MRI studies dedicated to the evaluation of changes in the LPM, such as hypertrophy, atrophy or muscle contracture associated, or not, with articular disc displacement[15]. MR images obtained in the oblique sagittal planes allow for a detailed observation of the LPM, articular disc, and mandibular head and fossa in the same image and beside a complete observation of, and the relationship between, the structures [16, 17].MR imaging in adult patients before and after mouth opening has suggested that volume changes occur in masticatory muscles between mouth opening and closing and that there is a difference between the changes in muscle volume. Although only small changes were observed in the masseter and medial pterygoid muscles, LPM volume significantly decreased during mouth opening. [18] Understanding the changes in the LPM images will help the clinician to understand better the clinical symptoms and allow for more accurate diagnosis of TMD, and therefore plan more effective treatment.

Materials and Method

Fifty skullswere examined and the lateral pterygoid plate was measured with the help of a vernier caliper.Fifty skulls from the anatomy department of The Saveetha Dental College and Hospital were taken to measure the right and left lateral pterygoid plates with the help of the Vernier caliper (Fig1).The measurement taken were evaluated. The mean value of the left and right pterygoid was calculated (Table 1)

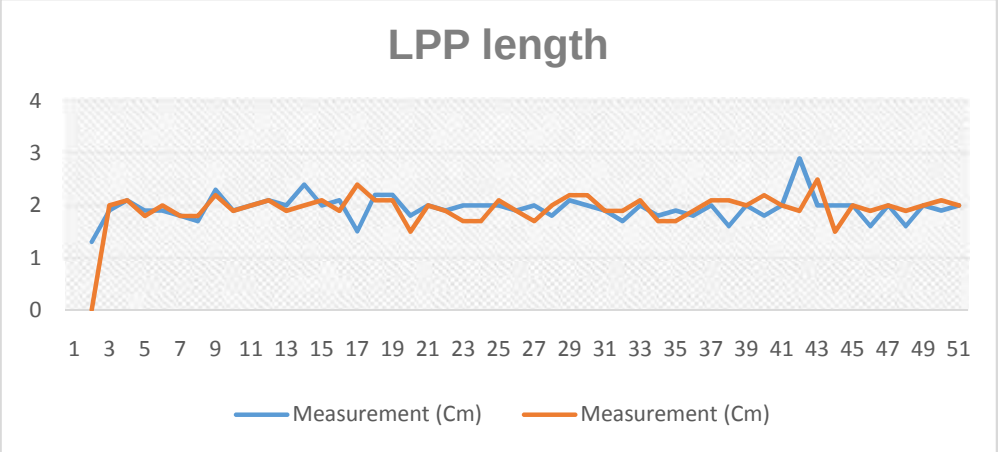

Figure 3: Graph showing measurement of left and right lateral pterygoid plate

Discussion

A broad thin plate that forms the lateral part of the pterygoid process, leads to an attachment to the lateral and medial surface known as the lateral pterygoid plate. According to L.Chris D Naidoo, in his article he had mentioned that the upper head of the lateral pterygoid muscle was approximately 33.3 mm in length and was significantly longer in males. There were no age-related differences. Approximately 29.5% of the fibers of this muscle were inserted into the meniscus of the temporomandibular joint [1].

One such study, conducted by Stratmann et al. in 2000, found that ". . . even after maximal impression of the buccal mucosa, a considerable residual distance remains between the ILP muscle and the buccinators fascia indented by the tip of the palpating forefinger."8 A systematic review carried out by Turp and Minagi (2001) also concluded that: "in the overwhelming majority of cases, palpation of the inferior lateral pterygoid muscle is impossible due to anatomical reasons."The study notes that these reasons include:

- Restricted space that does not allow access of the finger (a portion of this potential space is narrowed by the deep tendon of the temporal muscle)[3].

- Resistance by the tendinous origin of the buccinator muscle (pterygomandibular raphe)[4].
- Resilience of the buccal mucosa due to its close connection to the alveolar gingival that is firmly attached to the maxillary alveolar process [5].
- An obstructing deep origin of the medial pterygoid, which rests on the inferior face of the inferior head of the ILPM [6].

This may come as a surprise to practitioners dealing with TMDs in their practice, considering that epidemiological studies have shown that patients with these disorders frequently report the most tenderness to palpation of what was thought to be the “lateral pterygoid” muscles in this region [7-8]. TMJs had atrophy in both superior and inferior heads of the lateral pterygoid (SLPM &ILPM). However, atrophy was not present only in the ILPM. It has been concluded that since the SLPM only attached to the disc, the disc may displace interiorly very easily. Therefore, this situation will reduce the function of the SLPM. Reduced muscle function may cause muscle atrophy However, one must also consider that the same studies have shown that among individuals not suffering from or facial pain, the “lateral pterygoid” area is also considerably more tender than other masticatory muscles. If the LPM cannot be implicated for this tenderness, then, one must wonder what the actual cause of the pain on palpation is, if this muscle is, in fact, not accessible [9-12].

In another article where the relationship between the lateral pterygoid muscle and the meniscus was examinedand it was found out that 27.5% the upper head for the lateral pterygoid was attached to the condyle and 7.5% of other attachments of lateral pterygoid muscle to the meniscus. This study confirms that the lateral pterygoid muscle has variable attachments [13].
Macroscopically when the measurements of the upper and lower head of the lateral pterygoid plate were taken on 20 specimens, 13 specimens had both the heads of lateral pterygoid muscle (LPM) were present, whereas the rest7 had a separate fascia [14]. And according to another article, the LPM dystonia, a new technique is characterized by mandibular displacement towards the opposite side of the affected muscle. It may be associated with functional disorders affecting speech, swallowing, chewing and facial symmetry [15-18]. TMJs had atrophy in both superior and inferior heads of the lateral pterygoid (SLPM &ILPM). However, atrophy was not present only in the ILPM. It has been concluded that since the SLPM only attached to the disc, the disc

may displace interiorly very easily.

Therefore, this situation will reduce the function of the SLPM. Reduced muscle function may cause muscle atrophy [19, 20]. Statistical analysis, sensitivity, specificity, and negative and positive predictive values of the palpation technique were calculated and in 86 of 106 dissected specimens; a superficial fascicle of the medial pterygoid muscle was in direct proximity to the ILP muscle [21]. In these cases, a residual distance of 7.8 ± 3.2 mm remained between the ILP muscle and buccinators fascia indented by the tip of the examiner's finger. In 10 of 20 specimens with an absent superficial fascicle, the finger was able to reach the ILP muscle [22]. Hence it was concluded that it is recommended that the ILP muscle palpation technique should no longer be considered as a standard clinical procedure because it is nearly impossible to palpate the ILP muscle anatomically [23]. Since the morphometric analysis of the lateral pterygoid plate weren't mentioned in any of the articles hence this article has the measurement of the right and left lateral pterygoid plates.

Conclusion

The dimensions of lateral pterygoid plate differ on both sides and also from person to person (Table 1). By measuring its length, it allows us to understand the clinical significance like; difference in jaw movement and difference in the force applied since lateral pterygoid muscle is attached to it.

Abstract

Introduction: The mental foramen is a strategically important landmark during osteotomy procedures in implantology. Its location and the possibility that an anterior loop of the mental nerve may be present mesial to the mental foramen needs to be considered before implant surgery to avoid mental nerve injury. To provide anatomical information on the position, morphological variations and incidence of mental foramen and accessory mental foramen as they are important for dental surgeons, anaesthetists in nerve blocking and surgical procedures to avoid injury to neurovascular bundle in mental foramen area.

Material and Method: The present study was conducted using 120 dried human mandibles of both sexes. Size, shape and position of mental foramen and accessory mental foramen were determined using digital vernier calliper.

Results: Mental foramen was present in all observed mandibles and it was bilateral in position. Accessory mental foramen was present in 8 mandibles and was unilateral in position.

Conclusion: The knowledge about variation in size, shape and position of mental foramen and presence of accessory mental foramen may be helpful to the dental surgeons to achieve fullanesthesia and it's a guide for the implantologist to proceed with placing implant without damaging the nerve.

Key Words:*Mental foramen (MF), accessory mental foramen (AMF), mandible, premolar tooth.*

Introduction

The mental foramen is defined as the entire funnel-like opening in the lateral surface of the mandible at the terminus of the mental canal. Mental nerves and vessels passes through this foramen. This is contained entirely within the buccal cortical plate of bone.The mental foramen is the opening of mental canal, a branch of mandibular canal.Wall of the mental foramen is made up of cortical bone. The density of the foramen varies, as does the shape and definition of its border(1). Knowledge of the position of the mental foramen is important both when administering regional anesthesia, performing periapical surgery, dental implant surgery and endodontic treatment in mandible(2).

Foramen may occasionally be mis-diagnosed as a radiolucent lesion in the apical area of the mandibular premolar teeth.It also aids in interpreting anatomical landmarks in oral pathology andforensics(3).Mental foramen is a small foramen situated in anterolateral aspect of the body of the mandible. Normally, mental foramen is located below the interval between the premolars. It transmits mental nerve, artery and vein. Mental nerve is a branch of inferior alveolar nerve which supplies sensation to lower lip and the labial mucosa and lower canines and premolars. The most useful injection for anaesthetizing the mandibular teeth is the inferior alveolar nerve block(4).

To anaesthetise the anterior teeth, including the premolars and canines, it is possible to avoid giving inferior alveolar nerve block by injecting anaestheticsolution adjacent to the mental foramen. So,the study of position and morphological variation of mental foramen is very important because it will be helpful to localize the important neurovascular bundle passing through the mental foramen. Any foramen in addition to mental foramen in the body of the mandible is known as accessory mental foramen. Accessory mental foramen transmits the accessory branch of mental nerve. So, the knowledge of its position and incidence is helpful to dental surgeons to achieve complete anaesthesia because if this nerve is not blocked, anaesthesia will be incomplete(5).

Mental foramen is located in the face and in the body of the mandible at an equal distance from the superior and the inferior border and it is located below the interval between the premolars mental nerves and vessels passes through it. Accessory mental foramen is due to the branching of

mental nerve before passing through the mental foramen.Hence its shape,size and verification of its existence would prevent accessory nerve injury during periapical surgery. So the knowledge of its position and incidence is helpful to dental surgeons to achieve complete anesthesia because of this nerve is not blocked anesthesia will be incomplete. Mental nerve is the branch of the inferior alveolar nerve which supplies the sensation to the lower lip and the labial mucosa and the lower canines and the premolars. The most useful injection for anesthetizing the mandibular teeth is the inferior alveolar nerve block(4,5)

Mental foramen is also lie between the apices of the lower premolar,below the apex of the second premolar. Any foramen if addition to mental foramen is known as the accessary mental foramen in the body of the mandible (6). Variations like multiple or absent foramina are often encountered these variations in the position and the number of mental foramen have been reported in the pattern of their occurrence.Recent advancement in the clinical dentistry have increased the possibility of the procedures in the mental region and the detailed knowledge of the mental foramen and it may not only aid in the prevention of post-surgical neuromuscular complications and morbidity; but also hold the potential of contributing as the identification of maxillofacial anthropologic characteristic feature of different populations.

Human mandibles with over one mental foramen (MF) on one aspect do not seem to be such a rare discovery. Depending on the comparative size of the multiple MF traced on one side of a mandible, only one of them is considered as the main MF, while the others are regarded as accessory mental foramina (AMF). In order to distinguish an AMF from common buccal foramina without continuity with the mandibular canal, which are regarded as nutrient foramina, an AMF is defined as a foramen of an accessory bony canal originating from the mandibular canal (AMF). This foramen transmits the accessory branch of mental nerve. The knowledge of this foramen is essential to achieve complete anaesthesia(6,7).

The mental foramen (MF) is present on the anterolateral aspect on the body of the mandible. It transmits mental nerve and vessels. Mental nerve which is a branch of the inferior alveolar nerve supplies sensation to lower lip, labial mucosa, lower canines and premolars.Anaesthetising the anterior teeth together with premolars and avoiding inferior alveolar nerve block is feasible by

injecting anesthetic solution adjacent to the mental foramen (7).

Figure 1: Mental Foramen

Size of Mental Foramen

The average size of the foramen is 4.6 mm horizontally and 3.4 mm vertically on the lateral surface of the mandible.(6) The foramen is usually larger on the left side of the mandible. Based on its radiographic appearance, the mental foramen has been classified by Yosue and Brooks (2) into

four types:

Type I: mental canal is continuous with the mandibular canal

Type II: the foramen is distinctly separated from the mandibular canal

Type III: diffuse with a distinct border of the foramen

Type IV: unidentified group

Location

Anatomical variations occur concerning the mental foramen's location17,18. It is usually found more coronal than the mandibular canal.19,20Agthong et al.21 indicated, the foramen was 28 mm from the midline of the mandible and 14 to 15 mm from the inferior border of the mandible.(7) Similarly, Neiva et al.14 reported the foramen was 27.6 mm (range: 22 to 31 mm) from the midline and 12 mm (range: 9 to 15 mm) from the most apical portion of the lower

cortex of the mandible. Other
authors (8) commented the foramen was usually found halfway between the crest of bone and the inferior border of the mandible. However, this finding could be influenced by the amount of crestal bone loss.

Position

The positionof the mental foramen with respect to the teeth of the lower jaw
were classified according to the method ofTebo and Telford, 1950.

I. [Table/Fig-1]: Position of Mental Foramen in relation to teeth (Teboand Telford Classification)

1-Foramen lying on a longitudinal axis of passing between the canine and first premolar.
2-Foramen lying on the longitudinal axis of the first premolar.
3-Foramen lying on the longitudinal axis passing between first and second premolar
4-Foramen lying on the longitudinal axis of the second premolar
5-Foramen lying on the longitudinal axis passing between the secondpremolar and first molar.
6-Foramen lying on the longitudinal axis of first molar.The foramen which lay on a longitudinal axis which passed between the canine and the first premolar.

Detection of the Mental Foramen on Radiographs

Panoramic Films Radiographic assessment of the mental foramen must be interpreted cautiously. Jacobs et al.36 reported the foramen was detected on 94% (N = 545) of panoramic radiographs, but clear visibility was only attained 49% of the time. Similarly, Yosue and Brooks15 noticed the foramen on 87.5% (N = 297) of panoramic radiographs, and it was distinct 64% of the time. In another investigation in which four skulls were radiographed, (mean: 0.2 mm; range: 0.0 to 0.5 mm). It can be concluded that neither periapical nor panoramic films precisely portray the amount of bone coronal to the mental foramen.(9)

Ct Scans

CT scans are more accurate than conventional radiographs. Nevertheless, conventional radiographs can usually be used if potential radiographic distortions are taken into account(10). However, if it is difficult to locate the inferior alveolar canal or the mental foramen,

consideration should be given to obtaining a CT scan.

Conclusion

The anatomical variability of the position of the mental foramen should always be considered when performing periodontal or endodontic surgery in the area from canine to root of first molar tooth. The knowledge about variability in position of mental foramen and presence of accessory mental foramen is important in order to avoid nerve damage in connection with surgical procedure and to achieve complete effect ofanesthesia after mental nerve block.

Morphometric analysis of Foramen Magnum for Sex determination

Jayajanani.S [1], Jayashri.P [2]

Graduate Student [1],Senior Lecturer [2], Department of Public Health Dentistry,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Identification of human skeletal remains is the most important task for a forensic anthropologist during forensic examinations. The need for methods to estimate sex from cranial fragments becomes apparent when only a part of skull is brought for identification. In forensic or archaeological context estimation of sex is a very important step in the identification of any human skeletal remains discovered. Skull is one of the commonest parts of the skeleton used to determine the sex, and it is probably the second best region of the skeleton, next to the pelvis for this purpose. Foramen magnum is an important landmark of the skull base and is of particular interest for anthropology, anatomy, forensic medicine, and other medical field. The foramen magnum is an important anatomical opening in the base of the skull through which the posterior cranial fossa communicates with the vertebral canal. It is also related to a number of pathological conditions including Chiari malformations, various tumours, and occipital dysplasias. The aim of the review was to analyse the morphology of the foramen magnum in adult individuals in relation to sex.

Key Words: *-Foramen Magnum, Morphometric analysis, Anthropology, Sex determination, Population studies.*

Introduction

Identification of human skeletal remains is the most important task for a forensic anthropologist during forensic examinations. The need for methods to estimate sex from cranial fragments becomes apparent when only a part of skull is brought for identification.Sex determination from skull morphology is important in medico-legal cases. In most of the forensic studies the skeleton will be incomplete and makes gender identification difficult. Sex determination is one of the first steps in the identification of any human skeletal remains discovered in a forensic or archaeological context [1]. The most accurate results are obtained when the entire skeleton is available for study; however, skeletal material derived from forensic and archaeological contexts is rarely complete and undamaged. Therefore, it is important to establish methods for determining sex from skeletal elements likely to survive and be recovered [2].

Foramen Magnum

The foramen magnum is a large opening in the base of skull, it is oval, wider behind with greatest diameter being antero-posterior. It contains the lower end of the medulla oblongata, the vertebral arteries and spinal accessory nerves [3]. The dimensions of the foramen magnum are clinically important because the above mentioned vital structures passing through it may endure compression such as in cases of foramen magnum herniation, foramen magnum meningiomas and foramen magnum achondroplasia [4]. The knowledge of foramen magnum diameters is needed to determine some malformations such as Arnold Chiari syndrome, which shows expansion of transverse diameter [5]. The dimensions of the foramen magnum are important prior to the cutting off of the foramen magnum lesions or posterior cranial fossa lesions, because more the antero-posterior diameter, greater is the contra lateral exposure [4]. The diameters and area of the foramen magnum are greater in males than in females, hence its dimensions can be used to determine sex in the medicolegal conditions, especially in the following circumstances, such as explosions, aircraft accidents and war fare injuries [5, 6]. Foramen magnum is about 3cm wide by 3.5cm anteroposteriorly [7, 8]. It is located midway between and on a level with mastoid processes. The foramen magnum is surrounded by different parts of the occipital bone, squamous part lies behind and above, basilar part in front and a condylar part on either side [9, 10]. On each side its antero-lateral margin is encroached by occipital condyles, hence the foramen magnum is narrow anteriorly.

The anterior edge of the foramen magnum is slightly thickened and lies between the anterior ends of the condyles. The posterior half of the foramen magnum is thin and semicircular. Upper ends of anterior and posterior atlanto-occipital membranes are attached to the anterior and posterior margins of the foramen magnum respectively, and their lower ends are attached to the superior surface of anterior and posterior arches of the atlas respectively.[6] The foramen magnum is a wide communication between posterior cranial fossa and the vertebral canal. The narrow anterior part of the foramen magnum has apical ligament of dens, upper fasciculus of the cruciate ligament and membranatectoria, both are attached to the upper surface of basioccipital bone infront of the foramen magnum. Its wide posterior part contains the medulla oblongata and its meninges. In subarachnoid space spinal rami of the accessory nerve and vertebral arteries, with their sympathetic plexus, ascend into the cranium; the posterior spinal arteries descend posterolateral to the brain stem, where as anterior spinal artery descends anteromedian to the brain stem. The cerebellar tonsils may project into the foramen magnum [9].

Studies on Foramen Magnum for Sex Determination

The most conspicuous feature of the occipital bone is the large foramen magnum through which the cranial cavity communicates with the vertebral canal. The anterior border of the foramen magnum is formed by basilar process of the occipital bone, the lateral border by the left and right ex-occipitals and posterior border is formed by the supraorbital part of the occipital bone [10]. A pair of large smooth protuberances, the occipital condyles lies lateral to each side of the foramen magnum. Each condyle articulates with the corresponding superior articular facet on the atlas vertebra to form an atlanto–occipital joint [11]. A number of studies has investigated the utility of this anatomical region for sex assessment employing morphometric traits using discriminant function analysis.Teixeria (1982) published an initial study on estimation of sex based on the size of the foramen magnum. His findings based on a small sample of 40 adult (20 males, 20 females) Brazilian skulls indicated that if the area of the foramen magnum was 963 mm2 or larger, it was a male skull and if it was 805 mm2or less it was female skull. In another study, Routal et al. (1984) found the dimensions of foramen magnum in Indian sample to be sexually dimorphic and reported up to 100% accuracy of correctly identifying sex using simple demarking points .Many other studies have been conducted on different populations with respect to sexual dimorphism in foramen magnum and occipital condyles using different statistical considerations [12,13,14,15,16,17,18].Gapert et al., (2009) used discriminant function analysis and

regression analysis on an eighteenth and nineteenth century British sample. The discriminant functions developed in the study predicted correct sex in 70.3% of all cases. Gruber et al., (2009) did not find any sexual dimorphism in the diameters of the foramen magnum in central European dry specimen dating from Pleistocene to modern times. The foramen magnum had low discriminatory power in sexual dimorphism in UNIFESP sample and accurately classified 66.5% skulls (Suazo et al., 2009). In French sample, Macaluso Jr., (2011) found a low level of sexual dimorphism in the cranial base and in this study maximum length of left occipital condyle and minimum distance from occipital condyles gave the best results with accuracy rate of 67.7%. A study on sexual dimorphism by RaghavendraBabu et al which was based on antero-posterior diameter, transverse diameter and area of foramen magnum in population of coastal Karnataka region revealed predictability of foramen magnum measurements in sexing the crania as 64.5% for transverse diameter and 86.5% for the antero-posterior diameter.

Foramen Magnum in Chinese Population

A metrical study of 84 mature male Chinese skulls conducted at University of Edinburgh, which showed mean foramen magnum length for Chinese type I skull of 35.71mm and breadth was 28.24mm, whereas Chinese type 2 crania had mean foramen magnum length of 35.21mm and breadth was 28.00 mm. The CT scan of foramen magnum of 200 children of all ages and 100 adults, showed an average foramen magnum length of 35mm in adults and that of children reached the adult size by 3-4 years of age [19]. In a presentation of Brazilian skulls, the area of foramen magnum was 673- 1195 mm2 for males and 591-961mm2 for females [20]. A study conducted at Govt. Medical College, Surat for dimensions of foramen magnum, study sample was composed of 141 adult skulls (104 males, 37 females) it showed following foramen magnum measurements. In males skulls anteroposterior diameter varied from 3 - 4.2 cm with an average of 3.55±0.28cm, transverse diameter was varied from 2.5-3.5cm with an average of 2.46±0.19cm, and area of foramen magnum was varied from 5.8-10.29cm2 with an average of 8.19±0.94 cm2. In female skulls the anteroposterior diameter was varied from 2.8- 3.5cm with an average of 3.20±0.28cm, transverse diameter was varied from 2.4- 3.2 cm with an average of 2.71±0.16cm and area of foramen magnum varied from 5.49-8.79 cm2 with an average of 7.71±0.90 cm2. The study showed male skulls anteroposterior diameter, transverse diameter and area of the foramen magnum were significantly higher than female skulls [21].

In a study computerized tomographic dimensions of the foramen magnum of 63 achondroplastic individuals were compared to standards established for nonachondroplastic individuals. The size of the foramen magnum in patients with achondroplasia was small at all ages, particularly in those with serious neurological problems [22]. In an anatomic metric study of foramen magnum of 100 male and 100 female skulls of normal white people of Spain showed a mean sagittal diameter of 36.2±0.3mm and the area of foramen magnum of 888.4±13.9mm2 in male skulls. In female skulls mean sagittal diameter was 34.3±0.4mm, transverse diameter of 29.6±0.3mm and the area of foramen magnum of 801±17.1 mm2. Foramen magnum dimension of male skulls were significantly higher than female skulls [23]. In a study conducted at St.John Medical College, Bangalore on 350 skulls (175 males, 175 females) for foramen magnum dimensions showed. In male skulls antero-posterior diameter of foramen magnum was varied from 2.8-4.1 cm with a mean of 3.42±0.24cm, transverse diameter was varied from 2.3-3.6cm with a mean of 2.85±0.23cm and the area of foramen magnum was varied from 5.6-11cm2 with a mean of 7.69cm2. In female skulls antero-posterior diameter of foramen magnum was varied form 2.2-3.3cm with a mean of 2.8±0.22cm and area of the foramen magnum was varied from 5.1-10 cm2 with a mean of 7.8±0.98cm2[24]. The fitted nonachondroplastic foramen magnum growth curves demonstrate that the maximum growth occurs in the first 18 months and slows thereafter. Indeed, the sagittal dimension almost doubles within the first 2 years, while the transverse dimension enlarges by half the original dimension. Growth of this area is essentially complete by 5 years. The achondroplastic foramen magnum is small at birth, and during the first year it has a very severely impaired rate of growth essentially in the transverse dimension. This markedly diminished growth results not only from abnormal enchondral bone growth but also because of abnormal placement and fusion of the synchondroses.

In a measurement of area of foramen magnum in 219 skeletons (170 males, 39 females) of Turkey, it was observed that mean area of the foramen magnum was significantly different (909.91±126.02 mm2 in males, 819.01±117. 24mm2 in females). Correlation coefficient between the area of the foramen magnum and sex was 0.27. The results confirmed that mean area of foramen magnum is lower in females than in males [21].

The occipital bone is frequently used in procedures that seek to determine the sex in forensics or anthropology. From qualitative point of view, the roughness of the nuchal lines and the

prominence of the external occipital protuberance are good indicators for the diagnosis of sex.

On the other hand, from a quantitative point of view, the indexes have been built from the dimensions of the occipital condyles and the foramen magnum, and various authors have reported its usefulness in determining the sex, particularly with incomplete skeleton or cranial bones fractured [25, 26, 27].Catalina-Herrera (1987) [28] indicated that the sagittal and transverse dimensions of the foramen magnum were significantly higher in men's skulls. Zaidi& Dayal (1988) [29] classified a sample of Indian skulls according to the shape and dimensions of the foramen magnum, reporting differences between the skulls of male and female, which was similar to the findings of Henríquez-Pino et al. (1995) [30] in the Brazilian skulls.

In another study, Günay&Altinkök (2000) [31] examined the usefulness of determining the dimensions of the fora- men magnum in the diagnosis of sex, and noted that the diameters were of some use, while the total area was not a good indicator. Uysal et al. (2005) [32] reported sexual dimorphism by analyzing the dimensions of the foramen magnum in 3D computed tomography with 81% accuracy in determining the sex, a level that was higher than that obtained by Gapert et al. (2009) [33] in a sample of British skulls from the eighteenth and nineteenth centuries.

Foramen Magnum in Chiari Malformation

Most of the modern articles that explain the foramen magnum morphology are related to the Chiari malformation, which is defined as ectopia of the cerebellar tonsil at least 5 mm below the foramen (Chiari malformation type I: CM-I) [34]. Less frequently such herniations are complicated with myelodysplasia (CM-II) and cervical encephalocele (CM-III), as well as abnormalities of the paraxial mesoderm and maldevelopment of the contents of the posterior cranial fossa or other diseases, e.g. hydrocephalus, tumours of the central nervous system, or Paget's disease. Generally, the size, in particular the transversal diameter and area of the foramen, is smaller in non-complicated CM-I, but significantly higher values for all its measurements were found in the case of CM-I complicated with tethered cord syndrome and for CM-II. In all of these cases the volume of the posterior cranial fossa was smaller than in healthy individuals. The correlation between foramen morphology and size of the posterior cranial fossa was also highlighted by Acer et al. It is worth mentioning that cranial constriction, spinal cord tethering, cranial setting, intracranial hypertension, and intraspinal

hypotension increase the risk of cerebellar tonsil herniation and abnormality of the foramen magnum [34].

The shape of the evaluated structure results from developmental changes that influence the morphology of the 4 principal parts of the occipital bone and the intra-occipital synchondroses that connect them. Based on previous observations [35,36], Richards and Jabbour [38] divided the proper foramen magnum as well as the entire surrounded hard (atlas, dens of axis) and soft elements (ligaments, membranes) into ventral and dorsal parts that comprise 2 functional matrices. The ventral one includes skeletomotor-related structures — the ventrolateral border of the foramen (extending to a line between the bilaterally located anterior intraoccipitalsynchondroses), anterior longitudinal ligament, ventral arch of the atlas, anterior atlanto-occipital membrane, apical ligament and dens of the axis, cruciform and alar ligaments, as well as the tectorial membrane which separates it from the dorsal matrix. All the listed structures are important for the proper movement and stabilisation of the skull. Unlike the ventral matrix, the dorsal matrix is less involved in head motions but transmits important neurovascular elements. It contains the posterior edge of the foramen magnum, spinal cord, meninges and subarachnoid space, posterior atlanto-occipital membrane, the dorsal arch of the axis, as well as the accessory spinal nerve and various vascular structures, as listed in the introduction. As was stressed above, any abnormal development of the listed structure may significantly change the morphology of the foramen. The most common type is the previously presented Chiari malformations [34]. However, a number of brain and meningeal tumours, as well as various occipital dysplasias particularly assimilation of the atlas with the occipital bone and irregular formation of the occipital condyles may also cause encroachment into the foramen [34, 37]

Ford reported that the length of the fora- men increases more rapidly during the prenatal period when compared to its breadth. However, recently published data [38] shows that the in utero elongation of the foramen magnum from the 7th gestational month until birth is secondary mainly to the increasing length of its dorsal unit, while the length of the ventral unit does not differ significantly.

Such growth changes reverse in the early postnatal period (0–6 months). The dynamics of the process slow down after 1 year of age, when the dorsal unit reaches mature size but the length of the ventral unit continues to increase slowly until both anterior intraoccipitalsynchondroses become fully calcified (< 8.2 years). The postnatal period is also characterised by growth where changes in breadth dominate over changes in length. The breadth-dominated growth pattern is even longer and continues un- til about 9.5–10.0 years of age. Secondary to those

changes, the foramen index also changes from 62.7– –65.7% in the very early stages of the prenatal period to 69.8–71.0% at 0.75–2.5 years, and later be- comes more stable at 62.7–79.9%, with a mean value 78.88 ± 4.25% for adults (> 18 years). Un- like in the present results, in adult native South Africans, a high predilection of dolichotrematous and low frequency of meso- and brachytrematous foramina was found by De Villers. However, similar to our data, a much greater range of the index value (71.0–111.0%) was presented by other authors. All the authors note an oval or oval-to-round form of the foramen magnum as the dominant one for modern adult Homo sapiens. However, the shape may change during ontogeny. Richards and Jabbour [42] found 8 developmental variationsthat were noted in 470 examined skulls during various stage of human life from the 7th gestational month to 21 years of age. During the foetal period, the following forms were seen: a bi-rounded oval, a ventrally wide oval, a bi- pointed oval, and a dorsally convergent oval. According to the authors, a predominance of the oval variations was also visible during the postnatal period due to the growth of the anterior intraoccipitalsynchondroses. Similar to the current examined human population, in which the frequency of longitudinally oval (mostly bi-rounded and ventrally wide) and round types (two semicircle) were similar, the main tendency pointed by Richards and Jabbour [38] was an increase in the ventral breadth of the foramen making the foramen anteriorly wide, not fully circular. A low incidence of the proper circular variation was also found in the currently examined population. The differences in the frequencies of each variation may be secondary to various geographic and age ranges since most of the archaeological skulls (4500–100 years old) came from North America and their biological age was below 21 years of age. However, the main objection to such results is the fact that the study was based mostly on dried skulls, without the possibility of establishing the correct developmental follow-up changes that may occur in individuals.

Studies in South Indian Population

The average length of the foramen magnum (LFM) of South Indian male skulls was found to be 34.37 ± 2.38, which was lower than the Brazilian male skulls (35.7 ± 0.29) [39], the Turkish (37.2 ± 3.43) [40], Spanish (36.2 ± 0.3) [41], and the English populations (35.91 ± 2.41)11. Similarly LFM of the female skulls of the South Indian population was found to be 33.80 ± 2.56 which was lower than Brazilian population (35.1 ± 0.33) [39], Turkish (34.6 ± 3.16) [40], Spanish (34.30 ± 0) [41], and English populations (34.71 ± 1.91) [42]. Regarding the width of the foramen magnum (WFM), the values of the South Indian male skulls was found to be 28.98 ± 2.22 which was lower than Brazilianmale skulls (30.3 ± 0.20) [39], the

Turkish (31.6 ± 2.99) [40] , Spanish (31.1 ± 0.3) [41], and English populations (30.51 ± 1.77) [42]. The same measure for the female skulls of the South Indian population was found to be 27.60±2.67 which was lower than the Brazilian population (29.4±0.23) [39], Turkish populations (29.3 ± 2.19) [40], Spanish (29.6 ± 0.3) [41] and English populations (29.36 ± 1.96) [42] . The results demonstrated that sexual dimorphism is present in the foramen magnum and also racial difference is seen.

Conclusion

Generally speaking, the foramen magnum development is regulated by various biological (mostly genetic and hormonal) and non-biological factors during the pre- and postnatal periods. The non-biological group includes an asymmetrical foetal position in the uterine cavity, which may result in changes within muscle attachments. The majority of anatomical brain abnormalities also involve the asymmetrical deformity of cranial bones. Patients with achondroplasia were found to have an abnormally shaped foramen magnum, which was smaller in size, influencing the flow of blood and cerebrospinal fluid. In the postnatal period, the main role in abnormal, acquisitive bone formation is played by malnutrition and pathological states directly affecting bone mineralisation as well as prevalent customs.

Morphometric Analysis of Jugular Foramen

Tandra das. T[1],
Graduate Student[1], Assistant Professor[2], Department of Anatomy,
Senior Lecturer[3], Department of Oral and Maxillofacial Surgery
Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Sciences

Abstract

Introduction: The jugular foramen is difficult to understand and to access surgically; It is difficult to conceptualise because it varies in size and shape in different crania, from side to side in the same cranium, from its intracranial to extra cranial end in the same foramen, because of its complex irregular shape, its curved course, its formation by two bones, and the numerous nerves and venous channels that pass through it. The jugular foramen is a large aperture in the base of the skull. It is located behind the carotid canal and is formed in front by the petrous portion of the temporal, and behind by the occipital; it is generally larger on the right than on the left side. A study is done to measure the jugular foramen in right and left side using 50 dry skulls of unknown sex in Department of Anatomy in Saveetha Dental college.

Materials and Methods:50 adult unsexed, dry human skulls were examined from the Department of Anatomy of Saveetha Dental College and hospital, Chennai. All the skulls were normal and were devoid of any malformation. The skulls were used for tutorial teaching for dental students to measure the anteroposterior and transverse dimensions.

Result: The mean length of jugular foramen is found to be 15.07 mm. The mean breadth is 9.02mm

Conclusion: The present study observed the right jugular foramen to be larger than left. Findings obtained in the present study supports previously reported morphometric variations of jugular foramen besides adding data. These findings will be of utmost usefulness to ENT surgeons, neurosurgeons, forensic experts and radiologists.

Key Words:*jugular foramen, dry skull, size, calliper, extracranial.*

Introduction

The jugular foramen is the most complicated to appreciate and to approach surgically; It is difficult to gestate because it differs in size and shape in every crania, from side to side in the same cranium, from its intracranial to extra cranial end in the same foramen, due to its intricate irregular shape, its curved course, its formation by two bones, and the several nerves and venous channels that pass through it.Jugular foramen is a large aperture in the base of the skull. It is situated behind the carotid canal and is formed by the petrous part of the temporal bone and behind by the occipital bone. The jugular foramen is the main route of venous outflow from the skull and is characterised by laterality based on the predominance of one of the sides. Sigmoid sinus persists as internal jugular vein in posterior part of jugular foramen. Itis of great surgicalsignificance , several essential structuresruns through it. It transports nerves and vessels out of base of skull[1]. Jugular foramen lies between the occipital bone and petrous part of the temporal bone, it is elongated and irregularly shaped[2] .The 9 Th, 10 Th , 11 Th cranial nerves exit the cranial cavity through this foramen [3] .

Hovelacque was the first to propose the subdivisions of jugular foramen. A fibrous or bony septum that joins the jugular spine of petrous bone to the jugular process of occipital bone, divides the foramen into anteromedial or pars nervosa and posterolateral or pars vascularis [4]. The ninth cranial nerve , inferior petrosal sinus and meningeal branch of ascending pharyngealartery pass through pars nervosa while others pass through the pars vascularis. A dome is bony roof present in the jugular foramen . The presence of dome indicates the presence of jugular bulb [5]. The Anomalies of the jugular bulb are correlated with jugular foramen, as glomic tumours, which are usually in immediate contact with the structures that cross it[6]. Pathological processes affecting jugular foramen include intracranial meningiomas, paragangliomas, schwannomas, metastatic lesions and infiltration inflammatory process from surrounding structures such as the middle ear [7]. The most preferred treatment for these cases includes surgical resection.Ligation of the internal jugular is sometimes performed during radical neck dissection with the risk of venous infarction, which some adduce to be due to ligation of the dominant internal jugular vein [8] It is generally said that although the Jugular foramen is larger on the right side compared to the left, its size as well as its height and volume vary in different racial groups and sexes. The foramen's complex shape, its formation by two bones, and the numerous nerves and venous channels that pass through it further compound its anatomy [9,10] Since 1500 A.D severalscientific investigators including

Versaliuswere fascinated by the difference in shape and for the jugular foramen. Versalius (1543) in his illustrations of base of skull has mentioned compartmentations of jugular foramen. Manyresearch have been done including osteological, radiological and microdissections were performed to understand the puzzle of compartmentation and variations in the anatomy of jugular foramen, which led to conflicting observations.[11]

Intracranial and extra cranial lesions may affect the jugular foramen in addition to intrinsic abnormalities. Surgical resection is the treatment of choice in the majority of these cases. Development in microsurgical procedures have made possible the removal of advanced Jugular foramen lesions, which were initially thought to be inoperable [12] . As neurosurgeons become bolder in approaching this region, so the need for familiarity with the detailed anatomy of this region becomes greater. In Vasalius[13] book De HumaniCorporisFabrica it is mentioned that there are only three illustrations of the base of the skull. Two are identical apart from the labelling, and the left jugular foramen is much larger than the right. The third illustration is that of a skull held by a skeleton and the details of the base are indistinct, but the right jugular foramen appears to be larger than the left.[14]The foramen shows variation in shape, size, laterallity for the same skull the difference may be related to sex and race [15] .The present study was conducted to study the morphometry of jugular foramen, significance between sizes of right and left foramen.

Materials and Methods

50 adult unsexed, dry human skulls were examined from the Department of Anatomy of Saveetha Dental College and hospital, Chennai. All the skulls were normal and were devoid of any malformation. The skulls were used for tutorial teaching for dental students to measure the anteroposterior and transverse dimensions. Study was done on 100jugular foramen in 50 dry skulls.The length and width of jugular foramen, on both right and left side were measured using the Digital Vernier Calliper.[16]

Result

Table 1: The mean length of jugular foramen is found to be 15.07 mm .The mean breadth is 9.02mm.

	Range in mm	Mean in mm

Length: left	9.96 to 18.11	13.96 mm (±) 2.1215
Breadth: left	4.91 to 14.01	8.22 mm. (±) 1.91
Length: right	9.63 to 18.62	16.18 mm (±) 4.184
Breadth: right	6.10 to 13.78	9.82 mm. (±) 1.899

Discussion

The jugular foramen is difficult to understand and to access surgically; the problems in exposing this foramen are due to its deep position and the adjacent structures such as carotid artery anteriorly, the facial nerve laterally, hypoglossal nerve medially and vertebral artery inferiorly.[18]

The size and shape of the jugular foramen is obviously related to the size of the internal jugular vein and the presence or absence of a prominent superior bulb. The right foramen is usually larger than the left. There is a very wide variation in the anatomy of the intra cranial venous sinuses which accounts for variation in size and shape of jugular foramen. The difference in size of the two internal jugular veins is already visible in the human embryo at the 23 mm stage (8 weeks post-conception) and probably results from differences in the pattern of development of the right and left brachiocephalic veins.[19]

In the current study, the length and breadth of jugular foramen in the right side is greater than that of the left side. From these observation it can be said that the area of the right foramen is greater than the left foramen.

Sturrock[17] examined the jugular foramina in 156 skulls and found out that, in 69% of cases the right was larger than the left and in 23% the left was larger

Osunwoke E.A et.al did morphometric analysis of the jugular foramen of 120 dry adult skulls in Southern Nigeria and found the mean length of the right and left jugular foramen was 15.76±0.22mm and 13.39±0.23mm respectively, while the mean width of the right and left jugular foramen was 9.34±0.18mm and 7.54±0.20mm respectively. Significant difference between the right and the left jugular foramen was observed. The right jugular foramen was found to be larger than the left in Southern Nigeria [5].

According to Wysocki, Reymond and Skarzyński[16] (2006), difference in the results can be explained by racial and separate factors. As to the separate factors, these authors mention the significant correlation between the size of the Jugular foramen and also the hypoglossal channel with skull volume, thus pointing to the significance of cranial capacity for brain venous drainage.[11]

Patel and Singel[6] studied 91 Indian skulls (Saurashtra region) and observed in 60.4% cases larger right foramen, in 15.4% larger left foramen and in 24.2% equal on both sides. The jugular fossa was observed in 38.5% cases on the right side, 14.3% cases on the left side, 21% cases bilaterally and absent in 25.3% of skulls.

In study of Roma Patel and C.D.Mehta the mean transverse diameter of jugular foramen on the right and left were 12.17mm (range: 4.516.5 mm and 11mm (range: 5-16mm) respectively, while their sagittal diameter measured 7.9mm (range:3–12.5 mm) and 6.2 mm (range: 3–12.5mm) on the right and left respectively. Both diameters are more on right side. In the study done by Idowu on Nigerian skull, he found mean transverse diameter of jugular foramen on the right and left were 13.90 mm (11.6–17.0 mm) and 14.11 mm (9.2–20.2 mm), while their sagittal diameter measured 10.22 mm (6.8–14.4 mm) and 9.57 mm (7.4–12.8 mm) on the right and left respectively . According to study done on turks skull by Ekinci and Unur, the sagittal and transverse diameters of the left jugular foramen were 7.6 and 15.5 mm, respectively, and on the right 8.4mm and 16 mm, respectively . Pereira, GAM. studied total 111 skulls (of southern Brazil) and it was noticed that mean transverse diameter was 15.82mm on right side and 15.86mm on left side; mean sagittal diameter was 9.21mm on right side and 8.65mm on left side . In study of Hussain Saheb et al [11] it was found that the mean length of jugular foramen on the right and left were 23.62mm and 22.86mm, while their widths measured 7.83mm and 6.83mm respectively. The mean area on the right was 584.36mm and on the left was 493.30mm. Predominance of one of the two foramina appeared in 89.6% of cases. Predominance on the right was 64.8% and 24.8% on the left. 10.4% cases were equal on both sides.

Hatiboglu and Anil [12] studied 300 Anatolian skulls from the 17th and 18th centuries and observed that in 61.6% the foramen was larger on the right side and in 26% it was larger on the left side and in the reminder of equal size.

Some studies have added other parameters for morphometric analysis like Tekdemir observed no partition in their studies while Ekinci et al.found bony bridges in 20% and tripartite jugular foramen in 0.7%. Rhoton and Buza noted 26% bony bridges; this was bilaterally represented in 8%. A bony bridge in 3 (7.5%) of the jugular foramen with 1 skull bilaterally was found in this series. Rhoton et al and DiChiro et al observed a separate bony canal anterior to the pars nervosa in 6% of skulls, while Patridgenoted a frequency of 25%. This bony canal was for the exit of the IX cranial nerve. The present study did not notified a separate bony canal anterior to the pars nervosa. The smaller pars nervosa is relatively consistent in size compared with the larger and more variable pars vascularis.[20]

Navsa and Kramernoted a significantly larger exocranial area on the right in blacks but one of normal size in whites in South Africa.

All these previous studies shows correlation to our study .This study can be further carried out using increased sample size by adding gender and age correlation for better ratios , comparison and complete morphometric analysis.

Conclusion

The clinical significance of jugular foramen is very important during surgeries. Therefore, the dimensions of jugular foramen is very much necessary. The jugular foramen exhibits complex anatomical relationships and contains significant vessel and neural structures. The present study observed the right jugular foramen to be larger than left. Findings obtained in the present study supports previously reported morphometric variations of jugular foramen besides adding data. These findings will be of utmost usefulness to ENT surgeons, neurosurgeons, forensic experts and radiologists.

Saveetha University, Chennai, India

Abstract

Sella turcica is a saddle-shaped concavity in the body of sphenoid bone situated in the middle cranial fossa of skull, which is seen clearly on lateral cephalometric radiograph. Precise anatomical knowledge of the sellaturcica is important for neurologists and surgeons when operating in the region of cavernous sinus or the surrounding structures. The purpose of this study is to establish normative reference standards that could assist in evaluation and detection of pathological conditions. Precise knowledge of dimensions and anatomy of sellaturcica is required for effective and safe treatment of various pituitary disorders and in the procedure of pituitary ablation with radioactive implants. A Morphometric analysis of the Sella Turcica and structures in vicinity were done in thirty dry human skulls. The linear measurements in the sellaturcica were taken using a digital vernier caliper. Present study will provide the normal morphometric data for future reference and further studies.

Key Words:*sellaturcica, clinoid process, sphenoid bone, morphology, vernier caliper*

Introduction

Sella turcica is situated on the intracranial surface of the body of the sphenoid bone. 80% of the sella is occupied by the pituitary gland. Any abnormality or pathology in the gland could manifest from an altered size, shape and functions of the sellaturcica. Around 13% of brain tumour are found in the sellaturcica [1]. The anterior boundary of sellaturcica is completed by tuberculum sellae and laterally it is by middle clinoid processes. The posterior boundary represents a vertical plate of bone, the dorsum sellae on the superolateral margins, dorsum sella ends as small posterior clinoid process. In the middle of sella, the hypophyseal fossa is present which contains pituitary gland [2]. Any abnormality or pathology in the gland could manifest from an altered size and shape of the sellaturcica, to a disturbance in the regulation of secretion of glandular hormones; prolactin, growth hormones,etc [3].Sellaturcica is also usually used as a reference point with nasion to establish the base of the skull in cephalometric analysis. This is commonly done prior to orthodontic treatment.

All the anatomical details concerning the possible variants of the sellar region are taken into account by neurosurgeons in order to decide which approach is to be chosen. For this reason, neurosurgeons also perform anatomical studies on cadaveric specimens or dry skulls to obtain the additional information required[4].

Literature analysis showed that, the comprehensive craniometrical details of the sellar and suprasellar region of the sphenoid bone in the Indian skull is lacking though there is tremendous developments in neurosurgical techniques[4-5].

The enlarged sellaturcica on a radiograph has been found to be associated with adenomas, meningioma, primary hypothyroidism, prolactinoma, gigantism, acromegaly, empty Sella syndrome, and Nelson syndrome. A small size may lead to decreased pituitary function causing symptoms such as short stature and retarded skeletal growth.Research concerning the sella turcica has focused on both size and morphology [5-6].It is essential to study the morphology of sellaturcica to know the various anomalies or unusual appearance of sellar region. Therefore, the morphometric study was undertaken for present work involving the measurement of dimensions of sellaturcica[7].

Materials and Methods

A total of 30 dry human skulls of both sexes were examined from the Department of Anatomy at Saveetha Dental College and Hospitals, Chennai, Tamil Nadu. Keeping in view the aim of the study mentioned above, following observations were recorded in millimetres, using a Digital Vernier Calliper. The skulls with gross craniofacial malformations were excluded from the study. Figure 1 represents the distance between the lateral walls of the mid sellar region. Figure 2 represents the depth of the sella and Figure 3 represents the distance between tip of anterior clinoid process to posterior clinoid process.

Observations

The measurements of the sellar region are tabulated below in Table 1.

Table 1: Measurements of Sellar Region

S.NO	MEASUREMENTS	AVERAGE mm	RANGE-MALE mm	RANGE-FEMALE mm
1.	Distance between the lateral walls of the mid sellar region	11.8	11.5-18.5	10.5-14.5
2.	Depth of sella	8.59	5-11	5-9
3.	Distance between tip of anterior clinoid process to posterior clinoid process	11.01	9.5-11.5	5-11
4.	Inter distance between tip of anterior clinoid process	24.55	19.25-31.5	17-30

The anterior clinoid process is a constant landmark and showed pneumatization of one or both. The middle clinoid process was present in most of the skulls and absent in a few.

Results

In this current study, the distance between the lateral walls of the mid sellar region was found to be 11.8mm, the depth of the sella was found as 8.59mm, the distance between the anterior clinoid process to the posterior clinoid process was found to be 11.01mm and the inter distance between the tip of anterior clinoid process was 24.55mm.

Figure 1: Distance Between Lateral Walls of the Mid Sellar Region

Figure 2: Depth of Sella

Figure 3: Distance Between Anterior And Posterior Clinoid Process

Discussion

The importance of understanding the anatomy of sellar region and its variations is of utmost importance to neurologists and neurosurgeons dealingwith pathologies in this region. Also sellaturcica is of importance becausewithin its center lies the ‘sella point’ which helps in evaluation of craniofacial morphology[3].

The anterior and middle clinoid processes in the living are normally linked by a ligament which is not seen in the dry skull. If it does not ossify, it leaves behind a space between the anterior and middle clinoid process called the clinoid space. If the ligament ossifies it forms a foramen through which the internal carotid artery courses to supply the brain. This foramen is called “foramen clinoideocaroticum”, the carotico clinoid foramen [4]. The ossification of fibrous ligaments is considered a normal physiological process that occurs with age.

Sellar bridges may be sequelae of ossification in dura mater extending between the anterior and posterior clinoid process [5]. Ligamentous ossification occurring in the early age is possibly an extension of the normal ossifications of the anterior and posterior clinoid processes [6]. Formation of the sellar bridges may result directly from the pattern of sphenoid development or can be dictated by the physiological activities of chemical compounds that are involved in embryogenesis and buildup of the bones. Some proteins control the mechanism of hardening in ossifying structure or inhibit this process. For example, matrix Gla protein inhibits calcification in soft tissues while osteopontin slows down the ossification in hard tissues [7]. They reported a

total incidence of 22 % of various types of interclinoid bars. Increased prevalence has been reported in subjects with developmental craniofacial and tooth abnormalities [8].

Jones et al. [9] studied the incidence of sellaturcica bridges in 150 patients who had undergone combined surgical orthodontic corrections. They found sellar bridges in 16.7 % cases in the group treated by combined surgical and orthodontic means, whereas it was 7.3 % in the orthodontic-only group [10-11].

Erturk et al. [12] studied 119 adult dry skulls and 52 cadavers in which they found 8.18 % incidence of sellar bridges, higher on the right side (2.34 %) than on the left side (1.75 %) [13]. The absence of anatomic data on normal variation of the interclinoid ligament is a severe deficiency of modern anatomy textbooks. This study is very important for regional surgery; its anatomy has received less attention.

In the literature the anterior clinoid process has received more attention because it has been used by the surgeons, to gain entry into the clinoid space to explore the internal carotid artery and other structures in vicinity [14].The posterior clinoid process is less accessed for suchoperations. Any abnormality in the posterior clinoid process may compress the surroundingstructures especially the internal carotid artery and alter the attachment of the tentoriumcerebelli to the posterior clinoid process. The anterior clinoid process has been reported to be joined to the middle clinoid process by a fold of dura mater [15].

The size and shape of aperture in the centre of diaphragm sellae are variable. It is either round or elliptical in shape and is for the passage of stalk of pituitary gland. Its size is important in protecting the gland from transmitted pulsations of choroid plexus and for protecting the fibers of optic chiasma in cases of suprasellar extension of pituitary tumours. Variations in the morphometry of the sellar opening provides explanation for direction of growth of pituitary tumours towards cavernous sinus and supra sellar region [16]. The overall percentage incidence of round (60%) and elliptical (40%) shapes observed in the present study on Indian population of a wide age range could not be compared with the values reported in literature on adult Korean, Turkish British and Kenyan population [17].

The neural relationships of the sphenoid bone are among the most complex of any bone: the olfactory tracts, gyrus rectus, and posterior part of the frontal lobe rest against the smooth upper

surface of the lesser wing; the pons and mesencephalon lie posterior to the clival portion; the optic chiasm lies posterior to the chiasmatic sulcus; and the second through sixth cranial nerves are intimately related to the sphenoid bone. All exit the skull through the optic canal, superior orbital fissure, foramen rotundum, or foramen ovale, all foramina located in the sphenoid bone. The absence of such bony protection within the walls of the sinus may explain some of the cases of cranial nerve deficits and carotid artery injury aftertranssphenoidal operations [18]. The bone is often thinner over the carotid arteries than over the anterior margin of the pituitary gland.

The pterion and the “keyhole” are two important anatomical landmarks in the region of the greater wing in the lateral view .The pterion is located over the upper part of the greater wing. The “keyhole” is located just behind the junction of the temporal line and the zygomatic process of the frontal bone several centimeters anterior to the pterion. A burr hole placed over the pterion will be located at the lateral end of the sphenoid ridge. A burr hole placed at the keyhole will expose the orbit at its lower margin and dura over the frontal lobe at its upper margin.

In 1987 Quakinine& Hardy studied 250 sphenoid bones & found the average length was 8mm, average width was 12mm & depth was 6mm[19].Asad and Hamid showed that average width of sellaturcica was 14.9mm and depth was 9.9mm which is relatively higher than present study[20].

The surgical approach to sellar region by trans-sphenoidal, is already an established procedure in Neurosurgery and its complications are well described by some authors. Anatomical variations of this region are the causes of complications in this procedure. The most vulnerable structures along the sinus are: the internal carotid artery near the anterior wall of the sella, and optic nerves, located superolaterally[21]. The study had no aim to determine whether any of these structures were exposed within the sinus.

Most sellar region masses are pituitary adenomas and other neoplasms may occasionally be encountered in this location. The most common type of pneumatization of the sphenoid sinus was the sellar, and depending on the age group, sphenoid sinus was larger in males than females.The anatomical variations of structures of the sellar and parasellar regions varies widely and has been described in various forms [22].

Conclusion

Precise anatomical knowledge of the sellaturcica is important for neurologists and surgeons operating in the region of cavernous sinus or the surrounding structures.

All the linear measurements of the sellaturcica in the present study were within standard range. The results of the present study of sellar size may be used as reference guide for future studies about sellaturcica morphology with a larger population. A better understanding of these complex structures is essential in clinical diagnosis and treatment of disease.

A Comprehensive Review On The Effects Of Olestra

Denesh Raj Elangovan [1], Dhanalakshmi Ravikumar [2]

Graduate Student [1], Senior lecturer [2],Department of Pedodontics and Preventive Dentistry

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences,

Saveetha University, Chennai, India

Abstract

Olestra is known as fat substitute.It's also known as by its brand name Olean. It does not add on calories or cholesterol to the product. It's also used in food preparation such as potato chips.Originally it'sbeen approved by The Food and Drug Admiration (FDA) for the replacement of fats and oil. This review article highlights in detail about olestra.

Keyword: Olestra, fat, oil, Food, Drug

Introduction:

In 1996, the U.S. Food and Drug Administration (FDA) approved a new fat substitute, olestra (Olean), for use in “savory snacks” (potato, tortilla and corn chips; crackers; and extruded snacks) Federal Register 1996 [1]. Olestra has physical properties and taste and cooking characteristics similar to regular fats and oils [2].On the other hand, it does not contribute any energy to the diet because it is not hydrolyzed by gastric lipases and therefore it is not absorbed. Due to its unique properties, olestra can serve a zero-calories replacement for conventional fats and oils [2].

U.S Food and Drug Admistration History

In 1996, the U.S Food and drug Admistration (FDA) approved a new fat substitute called olestra or also known as Olean [1]. Despite its potential public health benefits as a nonenergy fat substitute, there is controversy concerning the effect of olestra. Experimental studies in both humans and animals find that olestra can sequester fat-soluble nutrient in the gut and thereby reduce their absorption [1]. This made the FDA in the addition of vitamin A, D, E and K [1, 2]. In approving olestra, the FDA made assumptions about the level of its consumption and its effect on serum micronutrients concentration. As a condition for approval, the FDA mandated a program of active post marketing [1]. The Olestra Post- Marketing Surveillance Study (OPMSS) was designed to investigate whether consumption of olestra containing food as part of self-selected diets[2].

Chemistry

Triglycerides, the energy yielding dietary fats consists of three fatty acids bonded to a glycerol [3]. Because olestra is synthesized from sucrose, it can bond with six, seven or eight fatty acids.

Effect on GI Tract

When olestra and a fat soluble nutrient comes in contact in the GI tract, a portion of the nutrient partitions into olestra [4]. The portion is then unavailable to the mixed intestinal micelles and is

removed from the body with the nonabsorbed olestra. Key factor controlling the partitioning mechanism include following:

1) The lipophilicity of the nutrient,

2) The relative amount of olestra and nutrient in the GI tract,

3) The time between consumption of olestra and nutrient [4]

Chemical CompositionOf Olestra

It is formerly called sucrose polyester, is the generic name of nonabsorbable, synthetic hexahepta and octaesters of sucrose and fatty acids, with the physical properties of conventional dietary fats [7]. The fatty acids are of chain length C12 and C24, derived from edible oils, such as soybean, corn or cottonseed. Olestra is not hydrolyzed by pancreatic lipase or colonic bacteria and it cannot be absorbed. Being nonabsorbable but with the physical properties of triglycerides olestras are potential; a caloric substitutes for dietary fat.

Vitamins Effects AndAbsorption

Clinical research shows a modest reduction in serum cholesterol and vitamin E levels. The effect on vitamin E absorbtion can be offset by supplementation of olestra with vitamin E [8]. The status of vitamin D and K and absorption of lipophilic drugs are not altered by daily consumption of 18g olestra. Although serum retinol levels are not reduced, additional research is focusing on effect of olestra on hepatic stores of vitamin A to assess the appropriateness of supplement [8]. Using olestra to reduce the amount of fat in high fat foods, without affecting other nutrients, should contribute to a diet lower in energy from fat and higher in energy from carbohydrate [9].

Drug Absorption

Studies were conducted in rats and humans which show that it did not effect absorption of lipophilic drug [8]. The drug tested included pranolol and the oral contraceptives norethindrone and ethynyl estradiol, which are the lipid soluble [10]. Diazepam was also tested due to its wide use. In humans, drug was tested in a milk shake made wither 16g olestra or 16g corn oil water [8]. It shows no different in amount absorbed [11].

Mineral Absorption

Olestra would not be expected to effect mineral absorption since minerals are not lipid soluble and it does not saponify in gastrointestinal tract [12].

Cholesterol Absorption

The absorption of cholesterol is decreased when olestra is included in the diet [8]. The effect has been observed when the source of intestinal cholesterol is either exogenous or endogenous [8].

Conclusion

It's been proven that olestra does not harm our human body unless it's been over consumed in a short period of time. 18g/day of olestra decreases the serum vitamin E levels to within normal range. The risk of over consumed can leads to cardiovascular disease, hypertension, obesity and diabetes.

A Comprehensive Review on Therapeutic Effects of Green Tea

Abiraamasri BL[1], DhanalakshmiRavikumar[2]

Graduate Student[1], Senior Lecturer[2,] Department of Pedodontics and Preventive Dentistry,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Green tea is one of the most popular tea that is commonly cultivated in China and Japan where it gained its legendary origin about 4000 years ago. Green tea is extracted from the leaves of Camellia sinensis that undergoes small amout of oxidation during production. It spreads world wide because of it important beneficial effects which include weight loss, prevention of cancer, lowers cholesterol level, cardiac problems, lowers blood pressure, diabetes, anti-bacterial, anti-viral, anti-microbial effect. Types of green tea is mainly based on harvesting period. Best quality of leaves are got the first flush of harvest. Constituents of green tea are amino acids, lipids, carbohydrates , enzymes, carotenoids and dietary minerals. Chemical components of green tea include xanthine derivative, vitamins and catechine derivatives. Catechins have antibiotic and immunomodulatory effect. Green tea also have side effects due to presence small amount of caffeine which is the xanthine derivative. Side effects include nausea, vomiting, irritability, insomnia, high blood pressure and rapid increase in heart rate.

***Key Words*:** *Green tea, Camellia sinensis, prevention of cancer, catechins, xanthine derivative, nausea, vomiting*.

Introduction

Green tea is the most popular tea that is extracted from the leaves of Camellia sinensis which undergoes minimal oxidative effect on production[1]. Its legendary origin is from china which is about more than 4000 years ago. Green tea cultivation is also distributed in other countries including Japan, Korea, Thailand, Vietnam, Asia, Darjeeling, Assam and Ceylon[2].The first green tea was exported from India to Japan during the 17th century. It is estimated that about 2.5 million tons of tea leaves are produced each year throughout the world, with 20% produced as green tea, which is mainly consumed in Asia, some parts of North Africa, the United States, and Europe [3]. The association between tea consumption, especially green tea, and human health has long been appreciated [4]. Green tea and black tea are processed differently during manufacturing.Green tea gained its popularity in west where they commonly prefer black tea because of their production. Black tea is processed in way to allow fermentation whereas green tea processing avoids fermentation process. Green tea gains its popularity in west due to it high beneficial effects which include weight loss prevention of cancer, diabetes, heart disease, decreasing cholesterol level, lowering blood pressure and tooth decay. It is used as raw materials in beverage industries, dietary supplements and cosmetics[5]. There are various types of green tea which is based on harvesting period and growing conditions[6]. Based on growing condition, green tea is of two types- those grown under sun shine and those grown under shade. First harvesting period is between april to early may. Second harvest is between june through july. Third harvest is from late july to early august. Occasionally there might even fourth harvest. Only first flush brings good quality of leaves. Green tea contains variety of enzymes, amino acids, carbohydrates, lipids, sterols, polyphenols, carotenoids, tocophenols, vitamins, caffeine and related compounds, phytochemicals and dietary minerals[5]. There is a evidence that large volume consumption of green tea causes oxidative stress, liver toxicity and reduction in cancer such as breast, prostate, ovarian and endometrial cancer.

Chemical Constituents

Chemical contents of green tea are xanthine derivatives, vitamins and catechins. Xanthine derivatives includes theophylline, caffeine, theobromine, glutamide derivative. Nutritional components of green tea are vitamin A, vitamin C, fluoride and potassium[7]. All tannins in green tea are catechins. Tannin is a gallic acid ester of a carbohydrate or phenolic compound.

Tannins are acidic due to phenolic hydroxyl groups in gallic acid moiety. They also act as antioxidants and forms complexes with metals. Tannins in tea are hydroxylatedflavanoids. Catechins also have antibiotic and immunomodulatory effect.The preparation methods influence the catechins both quantitatively and qualitatively; the amount of catechins also varies in the original tea leaves due to differences in variety, origin, and growing conditions[8]. The preparation of fresh green tea cannot totally extract catechins from the leaves; therefore, the concentration found differs from the absolute values determined through the complete extraction of leaves [9]. Green tea does not appreciable amount of these catechin dimmers. They also have beneficial health effect such as neuroprotective activity, anti-inflammatory, anti-ulcer, anti-viral, anti-bacterial and anti-parasitic effect[10].Epigallocatechin 3-gallate (EGCG) which is a derivative of catechin constitutes 50%-75% of the total flavonoid content in green tea. EGCG is a potent antioxidant and act to inhibit a number of physiologically important enzymes. It might also have therapeutic application in the treatment of some types of cancer, chronic fatigue syndrome, neurodegeneration, periapical lesions and regulating HIV viral load.Tea components possess antioxidant, antimutagenic, and anticarcinogenic effects and could protect humans against the risk of cancer by environmental agents [11]. Sano et al. [14]reported the inhibitory effects of green tea leaves against tert-butyl hydroperoxide-induced lipid peroxidation, and a similar antioxidant effect on the kidney was observed after oral administration of the major tea polyphenol EGCG. The antioxidative potency of crude catechin powder and individual catechins was tested in experiments using the active oxygen method. Crude catechins reduced the formation of peroxides far more effectively than dl-α-tocopherol [12]. Shim et al. [16].studied the chemopreventive effect of green tea among cigarette smokers and found that it can block the cigarette-induced increase in sister chromatid exchange frequency.

Beneficial Effects

Green tea is known world wide only due to its high beneficial effects and that includes cavity prevention, cancer prevention, leukemia, brain functioning, diabetes, kidney failure prevention, weight loss, anti-viral and anti-bacterial effects[13].

Obesity

The effects of tea on obesity and diabetes have received increasing attention. Tea catechins, especially EGCG, appear to have antiobesity and antidiabetic effects [15]. African black tea extract has been shown to suppress the elevation of blood glucose during food intake and

reduce the body weight in KK-A(y)/TaJcl diabetic mice [17]. Although few epidemiological and clinical studies have shown the health benefits of EGCG on obesity and diabetes, the mechanisms of its actions are emerging based on various laboratory data. These mechanisms may be related to certain pathways, such as through the modulations of energy balance, endocrine systems, food intake, lipid and carbohydrate metabolism, and redox status [18].Recent data from human studies indicate that the consumption of green tea and green tea extracts may help reduce body weight, mainly body fat, by increasing postprandial thermogenesis and fat oxidation. In a randomized, double-blind, placebo-controlled, cross-over pilot study, six overweight men were given 300 mg EGCG per day for two days. Fasting and postprandial changes in energy expenditure and substrate oxidation were assessed. Resting energy expenditure did not differ significantly between EGCG and placebo treatments, although during the first postprandial monitoring phase, respiratory quotient values were significantly lower with EGCG treatment compared to the placebo. These findings suggest that EGCG alone has the potential to increase fat oxidation in men and may thereby contribute to the antiobesity effects of green tea. However, more studies with a greater sample size and a broader range of age and body mass index are needed to define the optimal dose [19].

Cavity Prevention

Green tea contains fluoride which helps to prevent cavities and strengthens teeth. Green tea is also said to kill oral bacteria that may bring bad breath.

Cancer Prevention

Breast cancer

In recent research it is found that premenopausal women who consumed more green tea had a lower number of lymph node metastases. In postmenopausal women greater consumption of green tea correlated increased expression of estrogen and progesterone receptor, which implies more differentiated tumor cells and prognosis better. Women with stage I or II breast cancer who consumed five or more cups of green tea a day had recovered more faster than those women who consumed less cups of green tea[20].

Leukemia

Green tea extract is a potent nucleoside transport inhibitor, which repair DNA after chemotherapy. EGCG which a green tea extract is used as an nontoxic adjuvant therapy for leukemia.

Brain Functioning

Green tea helps to protect brain from oxidative stress and lowers monoamine oxidase activity. Green tea in general, as well as phenolic components- catechins and epigallocatechingallate have been found to be effective at inhibiting MAO and lowering peroxide levels in glial cells in the brain[21].

Effect On Hair

Green tea polyphenols are only recently understood as positive factors in hair growth and follicle health. They possess some of the mechanisms of action as including inhibition of apoptosis (programmed cell death), radioprotection of follicle cells, profound antioxidant activity, and potential follicular inhibition of TGF-beta [22]. Green tea is an herbal dihydrotestosterone reliable contrarian. A high intake of green tea correlates to higher levels of sex hormone-binding protein globulin (SBGH) which carries hormones like testosterone around the body in a bound, unusable form so that tissues cannot use it directly. Testosterone is usually carried around the body by this binding protein, therefore, reducing levels of free testosterone, so that it cannot be converted to dihydrotestosterone (DHT) in the hair follicle, which is thought to shorten the hair cycle and cause hair loss in men. Green tea is thought to affect the 5α-reductase type I enzyme, which converts testosterone to DHT [23]. Although these findings are at preliminary stage these studies suggest that further analysis in this regards can prove to promising in future.

Effect on Cardiovascular Disease

Another gem associated with green tea is its ability to protect from cardiovascular diseases. Heart diseases are associated with a numberof risk factors and are most prevalent in the Western world, probably as a result of the lifestyle in this part of the world, which includes a diet high in saturated fats and low physical activity, and the large proportion of the population who smoke cigarettes have a high blood pressure. Green tea appears to be cardio-protective[24,25].Regular consumption of green tea also inhibits atherosclerosis. Ground green tea consumption decreases susceptibility of plasma and LDL to oxidation and also modulated cholesterol metabolism and might prevent initiation and progression of

atherosclerosis. Green tea has been shown to effectively lower LDL Cholesterol, triglycerides, lipid peroxides and fibrinogen while improving the ratio of bad / good cholesterol i.e. Ratio of LDL to HDL cholesterol. The potent antioxidant effect of green tea inhibits the oxidation of KDK cholesterol in the arteries which plays a major contributor role in the formation of atherosclerosis. People who drink at least three cups of green tea every day, a 2% lower risk of suffering a stroke is observed as compared with those who drink less than a cup a day [26]. Regular drinking of green tea seems to lower the chance of getting high blood pressure. The loss of arterial elasticity is one of the cause of high blood pressure. With age, this elasticity is lost and thromboxane is one cause of arterial constriction. Another cause of hypertension is an enzyme secreted by the kidneys called Angiotension converting enzymes (ACE). Green tea seems to block thromboxane as well as ACE production and appears to be their natural inhibitor which significantly reduces the blood pressure.

Effect on Renal Disease

Green tea has a protective effect on renal failure. Decreased kidney function due to aging and kidney failure are a frequent cause of death. A preliminary study in Mansoura University in Egypt has explored the possibility to protect kidney function from life threatening failure with the frequent use of green tea [27]. They found that animals with kidney failure when treated with 50mg/kg EGCG from green tea had recovered significantly with glomerular filtration rate in 7 days, reduced malondialdehyde and inflammatory cytokines and increased glutathione (antioxidant levels) as compared to resveratrol and quercetin. This study indicates that in streptozotocin (STZ)-induced diabetic nephropathy, kidney function appears to be improved with green tea (GT) consumption which also prevents glycogen accumulation in the renal tubules, probably by lowering blood levels of glucose. Therefore, GT could be beneficial additional therapy in the management of diabetic nephropathy[28].

Anti-Carcinogenic Activity

Abundant experimental and epidemiological evidences accumulated mainly in the past decade from several research analysis worldwide provides a convincing argument that green tea polyphenols reduces cancer risk in a variety of animal tumor bioassay systems[29].In this study, the extracts of green tea and green tea polyphenols have exhibited inhibitory effects against the formation and development of tumors at different organ sites in animals. These include animal models for skin, lung, oral cavity, oesophagus, stomach, intestine, colon, liver, pancreas, bladder, mammary gland, and prostate cancers [30]. EGCG can inhibit

tumorigenesis during the initiation, promotion and progression stages in animal models of carcinogenesis [31] . The majority of invitro cell culture, in vivo animal, and clinical intervention studies provided strong evidences supporting a chemopreventive effect of green tea extract or purifies EGCG, in preventing prostate cancer, but results from epidemiological studies of green tea consumption are mixed [32]. As per the analysis, role of green tea in breast cancer development in humans is still unclear[33]. There is an inverse association for green tea intake and risk of ovarian cancer [34]. Women who regularly drank green tea when the study began were 37% less likely to develop colorectal cancer compared to infrequent green tea drinkers. Women who continued to drink green tea regularly throughout the study shows a decreased risk of colorectal cancer by 57%. Green tea lowers risk of gallstones and biliary tract cancers. A human pilot study recently confirmed the protective effects of green tea against lung cancer seen in cell culture and animal studies. It has been shown that because of green tea consumption, DNA damage caused by smoking was decreased, cell growth was inhibited, and cellular triggers for apoptosis (cell suicide) in abnormal cells increased [35].

Effect on Rheumatoid Arthritis

Inflammation plays a key role in Osteoarthritis (OA) and Rheumatoid Arthritis. An approach that decreases inflammation may facilitates the development of effective strategies for its treatment and prevention. Green tea polyphenols offer a promising new option for the development of more effective strategies for the same. In a study it was found that EGCG, the major and most active component of green tea polyphenol (GTP), protects human chondrocytes from IL-Iβ induced inflammatory responses [36].Although the efficacy of EGCG or green tea extract in human RA or OA using the phase-controlled trials is yet to be tested, an extensive evaluation of the potential risks or benefits of using EGCG alone or together with anti-rheumatic drugs may open a new area of research wherein EGCG or its synthetic analog could be developed to enhance its clinical appeal[37].

Effect of Oral Health

Among oral diseases like dental caries and periodontal disease, dental caries is a multifactorial infectious disease in which nutrition, microbiological infection, and host response play important roles. Streptococcus mutans is mainly responsible for causing dental caries. Green tea has proved to have anti- Streptococcus mutans activity [38]. A study has uncovered yet another benefit of green tea consumption. It has been found that routine intake of green tea may also help in fighting against these oral diseases. It promotes healthy teeth

and gums. The study analyzed the periodontal health of 940 men, and found that those who regularly drink green tea had superior periodontal health [39]. Apart from their polyphenols content, green is a natural source of fluoride and an effective vehicle for fluoride delivery to the oral cavity. The mean fluoride concentration in green tea is ~ 2.1 ppm, which lies within the acceptable daily intake. According to a report, after cleansing the mouth with tea, approximately 34% of the fluoride is retained and shows a strong binding ability to interact with the oral tissues and their surface integuments [40]. This fluoride content may have a beneficial impact on caries and may carry out a wide range of biological activities including prevention of tooth loss and oral cancer. This trace fluoride mineral reacts with the enamel of the tooth and makes it 50-70% less susceptible to decay or gum damage and helps get beautiful white teeth [41]. A recent study suggests that there is an explicit association between the consumption of green tea and oral health. It is also evident that green tea products have been used for preventing and treating several oral and periodontal diseases[42]. Its frequent consumption greatly reduces bad breath (halitosis). Knowing the role of periodontopathic bacteria in producing volatile sulfur compounds, antimicrobial polyphenols in green tea can improve bad breath by suppressing these bacteria [43]. In consequence, green tea has been considered as functional food for oral health and is widely used in toothpaste formulation. Greater the concentration of catechins better the health benefits. So the consumption of green tea in comparison to other beverages may be widely recommended[44].

Kidney Health

Decreased kidney function due to aging and kidney failure are frequent cause of death. Epigallocatechinegallate induces antioxidant enzymes in the kidney, as well as reduce uremic toxins in the blood and improve kidney function[45]. Kidney problems are often associated with high blood sugar and consequent glycosylation of various proteins. Thus there is a strong link between kidney failure and diabetes. Since, green tea has the ability to lower serum glucose, there is also another way to help kidney failure.

Weight loss

Green tea increases the metabolism hence we gain lose in weight. The polyphenols found in green tea works to intensify levels of fat oxidation ant the rate at which the body turns food into calories.

Anti-Viral and Anti-Bacterial Effect

Tea catechins are strong anti-viral and anti-bacterial agent which make them effective for everything from influenza to cancer.

Side Effects

Green tea contains 2% to 4% caffeine, which affects thinking and alertness, increases urine output, and may improve the function of brain messengers important in Parkinson's disease. Polyphenols might be able to prevent inflammation and swelling, protect cartilage between the bones, and lessen jointdegeneration[46]. They also seem to be able to fight human papilloma virus (HPV) infections and reduce the growth of abnormal cells in the cervix (cervical dysplasia). The mild side effects can range from nausea, vomiting, irritability and insomnia usually associated with the caffeine content found in the tea. Some of the serious, but rare side effects are symptoms of high blood pressure, a rapid heart rate, seizures and allergic reactions like hives, rashes and itching. Harmful effects of tea overconsumption (black or green) are due to three main factors: (1) its caffeine content, (2) the presence of aluminum, and (3) the effects of tea polyphenols on iron bioavailability. Green tea should not be taken by patients suffering from heart conditions or major cardiovascular problems. Pregnant and breast-feeding women should drink no more than one or two cups per day, because caffeine can cause an increase in heart rhythm. It is also important to control the concomitant consumption of green tea and some drugs, due to caffeine's diuretic effects [47]. Some studies revealed the capacity of tea plants to accumulate high levels of aluminum. This aspect is important for patients with renal failure because aluminum can be accumulated by the body, resulting in neurological diseases; it is therefore necessary to control the intake of food with high amounts of this metal [20]. Likewise, green tea catechins may have an affinity for iron, and green tea infusions can cause a significant decrease of the iron bioavailability from the diet [45].Green tea can block absorption of certain vitamin, nutrients and proteins, so you should drink it moderately. If you are pregnant, you should not drink green tea or any tea, because of the caffeine. Drinking large amounts of green tea when you are pregnant can cause neural tube birth defects in babies[48]

Conclusion

Green tea is one of the most important tea which has more beneficial effect. One of the most important effect of green tea is its antioxidative effect. Even though it has many beneficial

effect, it also have side effects like nausea, vomiting, rashes due to presence of small quantity of caffeine.

Abstract

A psychoactive drug which is used either as pharmaceutical or psychotropic drug is a chemical substance which crosses the blood brain barrier and acts mostly in the central nervous system where it affects brain function resulting in alteration of cognition, consciousness, perception and behaviour. Psychoactive compound most commonly brings about changes in mood and consciousness that the person who is using it can find pleasant feeling for example euphorbia or advantageous for example increased alertness and thus reinforcing. Psychoactive drugs are chemical substances that affect the brain functioning, causing changes in behaviour, mood and consciousness. While these drugs can be used therapeutically to treat both physical and psychological disorders, they are also used recreationally to alter mood, perceptions and consciousness. Psychoactive substances are used by humans for a number of different purposes to achieve a specific end. These uses vary widely between cultures. Some substances in psychoactive drug may have illegal or controlled uses while othersdrug may have shamanic purposes but still others may have used medicinally. Other examples would be social drinking or sleep aids. Caffeine is the mostcommonly used psychoactive substance unless it is illegal to use.

Key Words: Caffeine; Psychotropic drugs; Blood-Brain Barrier; Addiction; perception

Introduction

A psychoactive drug which is commonly known as psychotropic substance and it is used as a chemical substance that acts onthe central nervous system where it can alter the function of brain, that can result in changes which are temporary in consciousness, attitude, behaviour and perception .These psychoactive drugs can be used either recreationally or purposefully to alter mankind consciousness such as consumption of coffee, alcohol and cannabis, as entheogens for the spiritual purposes such as the mescaline containing peyote cactus or psilocybin containing mushrooms and also used as medications such as the narcotics usage helps in controlling pain , stimulants used in psychoactive compound used to treat narcolepsy and attentional disorders and antidepressants or antipyretic used for treating neurological and psychiatric illnesses[1].These substances can be used either recreationallyor purposefullyto alter mankind consciousness whereas etheogens are used for ritual, spiritual, orshamanic purposes, as an important tool for studying or controlling the mind. Some multiple categories of psychoactive drugs, which are used as a prescription medicines, have various medicaland therapeutic uses in medical field. For example, some drugs are used as anesthetics, analgesics and hormonal preparations and further used as antiparkinsonian and anticonvulsant and for the treatment of neurological psychiatric related disorders , as hypnotic drugs, stimulant medication and anxiolytics used in the treatment of ADHD and sleep disorders. There are some of the psychoactive substances used for rehabilitation and detoxification program for the person who are using psychoactive drugs. This is especially true of the powerful dissociative used mainly are salvia divinornum and deliriants used mainly are jimson weed. Most frequently used pure form of psychedelic drugs to be non-addictive for example mescaline, psilocybin and LSD. Psychedelic drugs such as amphetamine or empathogen- entactogens such as MDMA and MDA that can produce an euphoriant effect or addiction stimulant and thus have an additional potential[2].

Basic Classification of Psychoactive Drugs

Caffeine is used in the worldwide populations. The most commonly used psychoactive substance is caffeine ,unless many other psychoactive drugs is legal to use and usually used in nearly places in south india. In northern populations , adults around 90% consumes caffeine daily[3]. Psychoactive drugs are classified into 5groups :

1]AnxiolyticsDrugs. Example areBenzodiazepine

2]Euphoriants drugs, Example are 3,4-methyl dioxymethamphetamine (Ecstasy), 3,4-methylene dioxyamphetamine, 6-amino propylbenzofuron, Indopan

3]Stimulants – Stimulants are used as a substance in waking up one person thoughts, stimulating the mind and some people consumes the usage of caffeine daily without having knowledge about its use. The examples are nicotine, cocaine, nicotine and amphetamine.

4]Depressants are used for the purpose as narcotics, hypnotics and sedatives. The depressants may include all of the following anxiety reducing, calmative, sleep-inducing, anesthetizing substances, which can sometimes induce perceptual changes, such as dream images, and also evoke feelings of euphoria.

Examples: alcoholic beverages (ethanol), opioids, barbiturates, benzodiazepines

5]Hallucinogens, including psychedelics, dissociatives and deliriants. This category encompasses all those substances that produce distinct alterations in perception, sensation of space and time, and emotional states

Examples: psilocybin, LSD and nitrous oxide [4].

Psychoactive drugs are often prescribed to manage pain. The experience which is characterised as pain is regulated primarily by endogenous opioid peptides. The pain can be primarily cured by usage of psychoactives drugs that can be operated on the neurotransmitter system, which is also commonly known as opioid receptor agonists. This class of drugs can be highly addictive, and includes opiate narcotics, like morphine andcodeine[5].

Action of Psychoactive Drugs in the Brain

Neurotransmitters which may include dopamine, acetylcholine, serotonin, norepinephrine, histamine and about other two dozen dosage psychoactive drugs. The influence of psychoactive drugs is systematically limits the synaptic changes in the brain.The exceptional case would occurs when the drugbring about changes by itself in its own way in other parts of the neuron, such as the cell membranes. For example, hallucinogens are used to be believed medication in causingsynesthesiafor example seeing, hearing- the words ends with ing by

mimicking norepinephrine, acetylcholine and serotonin[6]. Psychoactive drugs are used in operating byaffecting a single mankind neurochemistry, which in turn causes changes in a one person behaviour, perception, cognition, and mood. There are many other ways in which psychoactive drugs which may affect the brain cells. Each drug has a particular action on either one or more neurotransmitter or neuroreceptor present in the brain cells. Drugs that may increase their activity in particular neurotransmitter systems are commonly known as agonists. Agonists basically act by increasing the synthesis of one or more neurotransmitters, by playing an important role in reducing its reuptake from the synapses, which may act by mimicking the action by its functions like binding directly to the postsynaptic receptor. Drugs that may reduce their neurotransmitter activity are commonly known as antagonists, and functions by operating as interfering with synthesis or blocking the postsynaptic receptors so that the neurotransmitters cannot bind to them each other[7].

Adverse Effects of Psychoactive Drugs

There are a number of side-effects related while consuming psychoactive drugs which is associated with the psychotherapeutic agents. These side effects may includes and are not limited to drowsiness, delirium, dry mouth, tremor, irregular heartbeat, weight gain, agitation, headache, insomnia, gastrointestinal distress, nausea, menstrual irregularity, weight gain, weight loss, sex drive loss, skin rashes, and sweating. Patients should have informed priority the information about their healthcare provider if they had previous experience any of these side effects. In some other cases, a dosage which is given lethally has to be in the form of easily adjustable or change of the prescription can also used to alleviate any discomfortable which is caused by psychoactive products . Additional medications which has to be involved may also be used as prescribed medication in order to address the severe forms of side effects for example the anticholinergic medication which may be prescribed is used in the treatment of muscle spasms usually caused by antipsychotic medications [8]. Tarsive dyskinesia is a condition which is characterized by an involuntary movements of the mouth and other locations which is present in the body which has been reported in some psychoactive drugs consuming patients who oftenly used to take the antipsychotic medication on a long-term basis for more than several years. In some other cases, the condition involving psychoactive drugs is considered to be permanent, although discontinuing or involving the change of medication used may be considered as halt or reverse dose in most of the patients.Agranulocytosis is a potentially serious illness

commonly observed in the surrounding in which the white blood cells responsible that can typically fight against the infection in the body are commonly destroyed, it is a possible side effect of clozapine and psychoactive drug such as another antipsychotic. Patients who is taking clopaminemedication should undergo weekly blood tests analysis used to monitor their white blood cell counts[9].Psychotherapeutic agents which is used as psychoactive agents can be contraindicated which is not recommended for use in patients with certain medical conditions like diabetes mellitus, hypotension etc..,These psychoactive drugs may also interact with other prescription dosage for the purpose of beneficial effects and more the counter the medications is used, either used in the magnification or used in reducing the intended side effects effects of consuming one or both the drugs. In some psychoactive related circumstances, psychoactive substances are used to trigger serious and even life-threatening, and physical side effects [10]. For the some particular reasons , individuals who are undergoing prescribed psychoactive medication should inform priorly about their mental healthcare provider and any other psychoactive drug prescribing doctor undergoing all medications which they are used to take, and patient who have any medical conditions such as diabetes , hypotension which has not been yet to be disclosed. Many psychoactive drugs which has been used are contraindicated in pregnancy patients, particularly contra indicated in the first trimester during pregnancy .Patients should check their blood level with their doctorconsultation about the risks which is commonly associated with the psychotherapeutic medications and undergone possible treatment options when planning for a pregnancy[11].

Treatment Using Psychoactive Drugs

Drug addiction of psychoactive drugs is used as a treatment option with medications andmainly withbehavioural therapies management which is used as a kind of psychotherapy. A combination of the two drug addiction level of psychoactive drugs was found to be the most effective approach form among drug addiction level.

1]Medical management of psychoactive drugs

The main problem concerned while using medications is that drug dependent patients often visiting the ward are relaxed and not concerned about taking medication regularly and thereby making the treatment ineffective. It also remains to be ethically controversial whether the patient who are not cooperative during treatment phase and person who are under medication can be forced to follow the medication properly or whether treatments option with

others who are not undergone medication are made to be potentially irreversible, the following effects observed should be used [12].

2]Behavioural Therapies used while consuming psychoactive drugs

Behavioural therapies are tried to replace the motivation skill involved in usage of drugs with the motivation to engage in other behaviour management.These behaviour therapies most commonly rely on the same principles which has been followed for more than a year are learning and motivation that are primarily used to describes the development of dependence [13].

3] providing various substitute or maintaining the treatment in a proper way:

The person who is consuming drugs are forced to given the drug which acts as a drug in their own way without induction of any hazardous effects. This treatment option is usually involved to treat opioids dependence on methadone and other drug substance are usually substituted for heroin. This will help the person who is addicted to drugs in their own way to quit drugs and maintaining their life in least harmful way and avoiding to experiment the cause of death. In spite the use of substitution therapy in providing least harm to the patient it is proved to be against the ethical issues[14].

Various Behavioural Therapies in Treating Drug Addiction

There are usually many behaviour therapies are followed in management of dug addiction. Among that, most common behaviour therapy are listed out below:

1) Cognitive behavioural therapy: involved usually in finding out which factors is responsible for the triggers drug taking and involved in response to adapt to the new environment
2) Relapse prevention therapy: these prevention therapy normally involved in avoiding various circumstances to avoid relapse mechanisms, helps to find out environmental and emotional triggers for drug intake and other sort of cravings.
3) Contingency management therapy: usually provided with large number of punishments or either rewards to make the people quit the drug addiction habits
4) Motivational therapy: involved in the motivation of the individuals by obtaining consent according to their own specific levels of drug addiction and maintaining their goals by motivating them in their own way[15].

Legality of Psychoactive Drugs

The legality of the psychoactive drugs that has been found to be the most controversial factors that occurs throughout the most of therecent history; particularly involved the second opium war and the another cause which occurs is Prohibition , these are the two main historical examples that was used to be found out in legal controversy related to the surrounding psychoactive drugs. However, many factors has been followed in the recent years among the factors, the most dramatically document that used to be prescribe followed regarding the legality of psychoactive drugs is the only Single Convention based on the Narcotic Drugs, which is found to be an international treaty systems that used to be signed in the year 1961 found to be an Act provided by the united nations [16].The act was signed by the 73 nations including the India, United Nations and United Kingdom , the Single Convention on the use of Narcotic Drugs was established as Schedules form used for the legality of each drug delivery system and purposefully laying down an international agreement used to fight for the addiction to recreational drugs levels by sale combatting, use of the scheduled drugs and tackling the drugs .All the countries including United Nations, India and United Kingdom has to be signed for the purpose to pass the treaty laws used to implement these rules within their borders. However, some of the countries that has to be signed the Single Convention on the use of Narcotic Drugs, most commonly involved countries such as the Netherlands, are more lenient in their delivery system with their enforcement of these laws passed for usage of narcotic drug [17].In the United States particularly, the Food and Drug Administration (FDA) has proved to be an authority over all other drugs, which may include mainly those psychoactive drugs. The food and drug administration act used to be regulated in which psychoactive drugs are used more than the counter and which may be only available with a prescription base .[18].However, all other certain psychoactive drugs, such as drugs, alcohol and tobacco which have been listed in the Single Convention on the usage of the Narcotic Drugs are subjected to be under criminal laws. The Controlled Substances Act passed in the year 1970 also used to regulates the recreational drugs which is used to be outlined in the Single Convention act on the usage of Narcotic Drugs. Alcohol consumed which is regulated by the state governments, but the federal National Minimum Drinking Age Act used to penalises the states for not only following a national drinking age but also helps in its usage content. Tobacco which has been regulated by all fifty state governments, mostly people accepted suchas restrictions and prohibitions of certain drugs, especially the hard drugs used to get more seduced, which are considered to be illegal in most of the countries.In the medicalconcern , psychoactive drugs

used as a treatment for various illness is more widespread and generally accepted thing. Little controversy may exists while concerning over the counter psychoactive medications in antiemetics and antitussives[19].Psychoactive drugs are commonly prescribed to patients with psychiatric disorders. However, certain critics believe that certain prescription psychoactives, such as antidepressants and stimulants, are overprescribed and threaten patients' judgement and autonomy.These psychoactive drugs was considered to be the major concern in the diagnosis of narcotic drug usage in the majority of the countries with decreasing populations to the usage of psychoactive drugs[20].

Homeostatic Activity While Using Psychoactive Drugs

Exposure of the environment to a psychoactive substance causesa drastic changes in the functioning and structure of the neurons, as the nervous system after consumption of psychoactive drugs usually tries to re-establish the homeostasis disrupted in the nervous system by the presence of the drug also called as neurospasticity in technical terms . Exposure of psychoactive drugs to antagonists for a particular neurotransmitter shows varying increase in the number of receptors occurring for that neurotransmitter, and the receptors play an important role within themselves to become more sensitive. This is usually calledas sensitization[21]. Physical dependence of psychoactive substance on antidepressants or anxiolytics may result in worse depression or anxiety feeling, respectively, as these are withdrawal symptoms of using psychoactive drugs . Unfortunately, a correlation occurs because the clinical depression which is also called as major depressive disorder which is more often referred to as antidepressants causes depression, are usually requested by the patients and prescribed for the patients who are in the depressed state ,but it was not clinically depressed [22]. Psychoactive drugs shows increasing amounts of dopamine levels in the brain which may rewards the pathway and also acts mainly in the central nervous system for the purpose of altering ones behaviour ,mood changes , perceptions [23].

Addiction Level of Psychoactive Drugs

Psychoactive drugs are most commonly associated with the drug addiction. Addiction is basically divided into two types namely psychological addiction, which occurs due to

psychological problems in which a person who consumes the drug are forced by someone and not by their own willingness in spite a negative feedback may be obtained by the patient in a complete physical or by societal consequence, and physical addiction is the another way of addiction in which the person already consuming the drug by their own concerns to avoid physically uncomfortable by the society or even by medically harmful withdrawal symptomsthat will persist in the body[24].All the drugs which are not physically addictive by human beings , but any activity of the mankind will stimulate the brain dopaminergic reward system, in simple words if any pleasurable activityoccurs in the brain will lead to psychological drug addiction level[25]. Many professionals such as doctors, teachers, self helpful groups, and businesses markers will be well specialized in drug rehabilitation program with varying degrees of success rates and many parents made attempt to influence the actions and better choices of their children in drug addiction regarding psychoactive drugs [26]. Common forms of rehabilitationprogram may include psychotherapy, support groups and pharmacotherapy, which uses psychoactive substances in better amounts to reduce cravings and physiologically withdrawal symptoms when theperson is undergoing through any detoxification [27]. Methadone is itself used as an opioid drug and as a psychoactive substance, which is used in the common treatment for heroin addiction patients and as is another opioid marketed which is commonly available are buprenorphine [28].

Effect of Psychoactive Drugs on Children

The administration of psychoactive drugs in children starts at a particular period of 6-17years of age which is more common in the society and growing at an alarming rate in world .These psychoactive drugs commonly causes the opposite to the intended effect, which usually condemning in the children to a life of the misery and ill health[29]. As the childs emotional control breaks down due to medication effects of psychoactive drugs, mood stabilizers may be added to the considerable quantity. These childrens who end up on four or five psychiatric drugs at once a time and a diagnosis was found to be bipolar disorder that occurs by the age of eight or usually ten [30]. Children and adolescents who suffers under serious emotional disturbance are no longer treated and survive only in the hospitals, but more often in foster homes and community residences, facilities involved in this drug addiction program are learnt to treat children historically and adolescents undergoing psychoactive therapy face

with serious behavioural symptoms. Children and adolescents are usually hospitalized for shorter lengths of stay in the hospital ,resulting in pressure to use interventions that are likely to have a rapid effect, such as medication [31].Exposure to psychoactive drugs can produce changes to the brain that are used in counteracting their effects, which may lead to physical dependence and, some believe, make their effects temporary.For example, halothane is a GABA agonist,and ketamine is an NMDA receptor antagonist[32].

Discussion

According to Nutt et al and Morgan et al, there are lack of correlation among 6000 individuals in terms of harms related to psychoactive drugs. According to Di Forti et al ,there was minute difference between cannabis and skunk,which is other forms of psychoactive drugs considered to be increasing in harms of cannabidiol varieties . According to Morgan and curran, ketamine which is the most hazardous drug belongs to psychoactive compound, ranks eighth in overall harms of psychoactive drugs. According to Griffiths et al, cialis ,form of psychoactive drugs was considered as positive effect in curing hallucinations. According to Krupitsky et al, ketamine has improved effects in treatment of heroin addicts. According to krebs et al, psychoactive drugs play an important role in decreasing alcohol misuse. According to Johansen et al, 3,4- methylenedioxy- methamphetamine was considered to be most effective as an adjunct therapy for post-traumatic stress disorder (PTSD) and therapy-resistant anxiety disorders. According to Caulkins et al, alternative harm matrices would be taken into count which has the context of drug usage associated with harmful effects. According to Walton et al, cannabis, a form of psychoactive drugs used as sedative and anti-convulsants has been implicated for its organic form and its components is used as analgesics, stimulation of appetite and anti-emetics. Efforts which are renewed are made to demonstrate the efficacy of psychoactive drugs as adjunct therapy to psychoactives. Psychedelic drugs such as amphetamine or empathogen- entactogens such as MDMA and MDA that can produce an euphoriant effect or addiction stimulant and thus have an additional potential[33].

Conclusion

Drug usage and addiction level of psychoactive substance are used to superimpose a substantial healthy burden on the society. Recent advances in the brain cell researches are used to find various ways to reduce that healthy burden. General anaesthetics comes under the classes of psychoactive drug which are used onthe patientshelps to block the pain and other sensations. Most of the anaesthetics used helps to induce unconsciousness, which commonly allows the patients to undergo medical procedures like surgery without physical problems related pain or emotional problems related to trauma. To induce the unconsciousness which is caused by psychoactive drugs mainly anaesthetics are helpful in affecting most common GABA and NMDA systems. Thus, the judicious use of psychoactive drugs are warranted for de-addiction and rehabilitation programs as it bring about alterations in the mood and consciousness.

A Review on Medicinal Values of Ginger

Yendodu Varshitha[1], Arvind. M[2]

Graduate Student[1],Professor[2],Department of Oral Medicine and Radiology

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai India

Abstract

Ginger is a medicinal plant that is widely usedin traditional systems of medicine. The two most active constituents of ginger based preparations are gingerol and shagaol. It has antiemetic, antipyretic, analgesic, anti-arthritic and anti-inflammatory activities. Ginger (Zingiberofficinale Roscoe) has strong antioxidant effects helping in production of free radicals. Studies have proved the anti-tumour and hepatoprotective effects of ginger. This review discusses the pharmacological properties and clinical uses of ginger.

Key Words: *Ginger, Zingiberofficinale ,Antioxidant, anti-tumour ,Hepatoprotective.*

Introduction

Plants are being used by humans in many ways such as food and spices. Ginger or Zingiberofficinale, Roscoe belonging to the family Zingeberaceae which is a herbaceous rhizomatous plant. Ginger, the rhizomes of the plant Zingiberofficinale is arguably one of the most widely used culinary agent and spice in the world. In addition to its culinary use, ginger also possess medicinal properties and has been used since ancient times world wideto treat ailments like cold, headaches, nausea, stomach upset, diarrhoea, digestive, gastrointestinal disturbances, rheumatic complaints, asthma, parasitic infections, arthritis and muscular discomfort[1-7].

Pharmacognocy

Ginger belongs to family Zingiberaceae, genus Zingiber, species Zingiberofficinale. The ginger plant was first cultivated in China and then cultivated in India. It is a perennial reed like plant about a 3 to 4 feet tall. The root is gathered when the stalk withers, it is immediately scalded washed and scraped to kill it and prevent sprouting. The roots of ginger are used as a spice in cooking. The main constituents are sesquiterpenoids with zingiberene as main constituent

Figure 1: Ginger

Ginger and Antioxidant Action

Antioxidants are the substances that have the ability to counteract the damaging effects of free radicals in tissues and thus are believed to protect against cancer and heart disease[8]. About 40 antioxidants arepresentin ginger[9]. [6]-Dehydroshogaol, [6]-shogaol and 1-dehydro-[6]-gingerdione were shown to be potent inhibitors of nitrous oxide(NO) synthesis in activated macrophages[10]. The CO2 extract from ginger roots has been shown tohave a significant effect in inhibiting DPPH (2,2-Diphenyl-1-picril hydrazyl), up to 90.1%. Ginger also showed a higher chelating capacity. Increased generation of reactive oxygen species (ROS) and reactive nitrogen species (RNS) are implicated in various liver diseases, and in the toxic manifestations of various hepatotoxins[11,12]. Ginger extracts, oleoresins and the volatile oils possess free radical scavenging effects, and are effective in scavenging the superoxide, hydroxyl, nitric oxide in vitro[13]. The phytochemical zingerone is also reported to be an effective scavenger of the free radicals like superoxide[14-16], peroxy[17] and peroxynitrite[18], and to also inhibit the formation of14peroxynitrite-mediated tyrosine nitration. Another important phytochemical of the ginger.Gingerol is also shown to scavenge peroxyl radicals, to inhibit the production of nitric oxide and reduce generation of iNOS in LPS-stimulatedcells[19].

Ginger and Hepatoprotection

Phytochemical studies have shown that the unique culinary and medicinal properties of ginger are due to the presence of phytochemicals like zingerone, shogaols, gingerols, pardols, β-phellandrene, curcumene, cineole, geranyl acetate, terphineol, terpenes, borneol, geraniol, limonene, β-elemene, zingiberol, linalool, α-zingiberene, β-sesquiphellandrene, β-bisabolene, zingiberenol and α-farmesene. Scientific studies carried out in accordance to the principles of modern system of medicine have convincingly shown that ginger possesses numerous health benefits like antimicrobial, antiviral, gastroprotective, antidiabetic, anti-hypertensive, cardioprotective, anticancer, chemopreventive and immunomodulatory effects. In vitro laboratory studies on animals have also shown that ginger to possess hepatoprotective effects, and to protect the liver against the toxic effects of diverse class of

xenobiotic agents like alcohol[20-21], country liquor[22], acetaminophen[23], heavy metals[24,25], CCl[26], paraben[27] and bromobenzene[28].

Pharmacological Effects

Anti-Cancer Effects

The anticancer effects of ginger are thought to be attributed to various constituents including vallinoids, viz. (6)-gingerol and (6)-paradol, shogaols, zingerone, and Galanals A and B[29,30]

Anticoagulant Effects

Ginger has been shown to inhibit platelet aggregation[31,32,33] and to decrease platelet thromboxane production in vitro[33,34,35]. Gingerol, shogaol, paradol, and gingerol analogues exhibited antiplatelet activities.

Antiemetic Effects

Elements in ginger which are responsible for antiemetic effect are anticipated to be the gingerols, shogaols, and galanolactone, a diterpenoid of ginger[36,37,38].

Anti-Inflammatory Effects

Ginger has been found to inhibit prostaglandin biosynthesis[39] and interfere with the inflammatory cascade and the vanilloidnociceptor[40]. Ginger has been shown to share pharmacological properties with non-steroidal anti-inflammatory drugs (NSAIDs) because it suppresses prostaglandin synthesis through the inhibition of cyclooxygenase-1 and cyclooxygenase-2.

Gastrointestinal Effects

There is evidence that ginger rhizome (root) increases stomach acid production. If so, it may interfere with antacids, sucralfate (Carafate), H2 antagonists, or proton pump inhibitors. In contrast, other *in vitro* and animal studies have revealed gastro protective properties[41,42]. Shogaol, generally more potent than gingerol, has inhibited intestinal motility in intravenous preparations and facilitated gastrointestinal motility in oral preparations. Ginger extract has also been reported to inhibit the growth ofHelicobacter pylori in vitro.However, Desai et al. observed a significant increase in the exfoliation of gastric surface epithelial cells following the consumption of 6g or more of ginger[43].

Antimicrobial Activities

Ingenol and (6)–shogaol, isolated from ginger rhizome, demonstrated antiviral activity[44].

(10)-gingerol has been reported as active inhibitor of Mycobacterium aviumandMycobacterium tuberculosis in

vitro. Gingerol and related compounds have been investigated for antimicrobial activities.

(6)- gingerol and (12)-gingerol, isolated from ginger rhizome, demonstrated antibacterial activity against Porphyromonas gingivalis , Porphyromonas endodontalis and Prevotellaintermedia

Anti Arthritic Effect

Crude ginger extract,(6) gingerolto reduce joint swelling in animals induced with rheumatoid arthritis and exhibited potent anti inflammatory action.[46]

Ginger Uses in Dentistry

A study based on laboratory investigations to investigate the antifungal activity of zingiberoffcinale (Ginger) on Candida albicans. Candida albicans (PTCC 5027, ATCC10231) was obtained from Iranian microbial collection and was confirmed by Germ Tube formation test. Ethanol ginger extract was prepared. The results showed that the ethanol extract was effective on Candida albicans. This study indicates that ginger extract might have promising resultson oral candidiasis[a]

In other study Paradol, which was derived from ginger root and certain zingiberaceae plants, protected mouse skin from a tumor inducing agent, and showed dose-dependent cytotoxicity in an oral carcinoma cell line (KB), with specific features of caspase-3-mediated apoptosis. Viable KB cells were reduced in number to less than 50% of untreated control when incubated with 50 lM [6]-paradol for 48 h. In addition, an ethanol extract of ginger mediated anti-tumor promoting effects, decreased the number of tumors in a Sencar mice skin tumor model[20].

In a study Acyclovir-resistant clinical isolates of herpes simplex virus type 1 (HSV-1) were analyzed in vitro for their susceptibilities to essential oils of ginger, thyme, hyssop, and sandalwood. The active components of essential oils might consist of lipophilic carbohydrates that interact with the lipid membrane. These antibacterial active substances might exhibit similar activities against viral envelopes. Acyclovirresistant clinical isolates were significantly inhibited by the essential oils, and the titers of HSV were reduced by 95.9% to 99.9%. Essential oils act by inactivating HSV before it enters the cell. The effective dosage for a systemic application of essential oils is rather high and leads to cytotoxic effects. Furthermore, a short-term systemic bioavailability makes a systemic application unlikely [21] Aqueous ginger extracts which was used to check antimicrobial activity

found to be efficient[22]. For treatment of tooth ache [11] As a sialogogue, to promote salivation [18]

Conclusion

Various pharmacological properties and possible clinical use of ginger is discussed. Further human studies will have to be done to validate the use ginger as a therapeutic drug. With its numerous medical uses ginger promises to be an effective therapeutic agent for various disease in the future.

A Review on Effect of Clonazepam in Burning Mouth Syndrome

S.Renuka[1],M.Sankari[2],
Graduate Student[1],Professor[2],Department of Periodontics,
Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Burning mouth syndrome (BMS) is a chronic or recurrent burning sensation in the mouth without an obvious cause. BMS is also named as stomatodynia, stomatopyrosis, glossopyrosis, glossodynia, sore mouth, sore tongue and oral dysesthesia.The prevalence of symptoms will be more in diabetic patients. This discomfort may affect the tongue, gums, lips, inside of your cheeks, roofof your mouth or widespread areas of your whole mouth. This review is to discuss the effect of clonazepam in burning mouth syndrome management.

Symptoms of BMS are relieved whenthe underlying medical condition, such as diabetes which is linked with cardiovascular, peripheral vascular, cerebrovascular, renal and psychological and ocular diseases [1] or yeast infection, is treated. Since BMS is a complex pain disorder, the treatment may not be constant for all patients. Drugs majorly used in treatment of BMS include Nortriptyline, Oral and topical clonazepam, Gabapentin, Pregabalin and alpha lipoic acid. Clonazepam, a benzodiazepine also widely used in the treating various chronic pain syndromes.This review elaborates the effect of clonazepam in the management of burning mouth syndrome.

Key Words*:clonazepam, pain, syndromes, sore mouth, sensation.*

Introduction

Burning mouth disorder (BMS) is an idiopathic condition described by a consistent burning, stinging or itching sensation in the tongue, with or without expansion to the lips, cheeks and oral mucosa.BMS is also called as glossodynia, glossopyrosis, glossalgia, stomatodynia, stomatopyrosis, sore tongue and mouth, burning tongue, oral or lingual parasthesia and oral dysesthesia[2], which occurs most commonly in peri and postmenopausal women.Theetiologyof BMS is unknown but it is thought to be multi-factorial, involving various local, systemic, and/or psychogenic causes [3].The risk factors for developing BMS includes thyroid disease, psychiatric illnesses, oral infections, drug use, dental treatment, vitamin/mineral deficiencies [4,5], Parkinson's disease, and chronic medical conditions including gastrointestinal and urogenital diseases[6,7-10]. Influenced patients regularly give different oral objections, including burning, xerostomia and taste modifications. BMS can appear suddenly or develops gradually over a period of time and the burning sensation become severe when you scald your mouth.BMS will not consistently associated with certain conditions such as chronic anxiety or depression, various nutritional deficiencies, type 2 diabetes (formerly known as non-insulin-dependent diabetes) and changes in salivary function but the treatment for these conditions has little impact on burning mouth symptoms. Recent studies have pointed to several cranial nerves dysfunction associated with taste sensation as a possible cause of burning mouth syndrome [11].BMS directly or indirectly affect the quality of the patient's life. Hence, management of this syndrome is very essential to prevent systemic dysfunctions. This review focuses on the effect of clonazepam in management of burning mouth syndrome.

Etiology

The cause of burning mouth syndrome can be classified as either primary or secondary.

Primary Burning Mouth Syndrome

Essential Burning mouth disorder When no clinical or lab variations from the norm can be recognized, the condition is called primary or idiopathic burning mouth disorder. Some examination proposes that idiopathic burning mouth disorder is identified with issues with taste and sensory nerves of the peripheral or central nervous system.

Secondary Burning Mouth Syndrome

Sometimes burning mouth syndrome is caused by an underlying medical condition. In these cases, it's called secondary burning mouth syndrome. It comprises ofdry mouth (xerostomia) , Nutritional deficiencies, such as a lack of iron, zinc, folate (vitamin B-9), thiamin (vitamin B-1), riboflavin (vitamin B-2), pyridoxine (vitamin B-6) and cobalamin (vitamin B-12), ill fitting dentures, allergic substances, GERD, Oral habiks like bruxism, diabetes, hypothyroidism, excessive mouth irritation, anxiety, certain medications, other oral conditions, such as a fungal infection of the mouth (oral thrush), an inflammatory condition called oral lichen planus or a condition called geographic tongue that gives the tongue a map-like appearance.

Classification

Lamey and Lewis (1989) classified BMS into three types depending on the intensity of pain [12].

1. Type 1 (35%) is characterized by patients having burning every day. The sensation of burning will be absent on waking and as the day continues, being maximal at night.This sort might be connected to systemic issue, for example, nutritional deficiencies and endocrine issue.
2. Type 2 (55%)Type 2 (55%) is characterized by burning sensation that happens each day, is present on arousing and regularly makes nodding off around evening time.This subgroup of patients frequently report mood changes, modifications in dietary patterns, and diminished yearning to mingle, which appear to be inferable from an adjusted rest design 3
3. Type 3 (10%)is described by intermittent sensation, show just on some days, with copying influencing irregular destinations, for example, the floor of the mouth, buccal mucosa, and throat. These patients frequently show tension and unfavourably susceptible responses, especially to nourishment added substances.

Pathophysiology

The pathophysiology of burning mouth syndrome (BMS) is complicated.It was originally considered a psychogenic illness; however, a neuropathic mechanism for BMS is currently

favoured. This is based on objectively measured abnormalities of physiologic responses of the trigeminal nerve in BMSpatients[13, 14].

The etiology is multifactorial with mounting evidence for a physiological basis. Axonal degenerative changes have been demonstrated in glossal terminal nerve fibres and sensory changes have been shown to be present in burning mouth patients, particularly perception of heat, cold, taste and nocioceptive stimuli [15-17]. Variations from the norm in trigeminal somatosensory evoked possibilities have been exhibited also [18]. This strongly suggests that there is a dysfunction of the small diameter afferent sensory fibres in burning mouth syndrome.

Imaging studies in patients have also suggested central nervous system changes [19, 20]. More recently, an enticing hypothesis has been proposed that burning mouth syndrome is associated with an alteration of gonadal, adrenal and neuroactive steroid levels. Woda et al. suggested that chronic anxiety or stress results in a dysregulation of adrenal steroids, a reduction in adrenal steroids will, in turn, lead to an altered production of neuroactive steroids in skin, mucosa and the nervous system [21].

The relationship with menopause is captured by the suggestion that the dramatic fall in gonadal steroids that occurs at that time further alters the production of neuroactive steroids. This “perfect storm” results in neurodegenerative alterations in small nerve fibres and areas of the brain related to somatic sensation. Thus explaining the peripheral and central changes already demonstrated in this condition [22-23]. There is aevidenceofhistopathological changes in nociceptive fibres in BMS patients [25]. However, a literature review by Galli et al demonstrated that both uneasiness and dejection may fundamentally add to the development of BMS [26].

A study by Mo et al indicated a neuropathic source for BMS, finding a loss of thermal sensitivity in individuals with this condition. Perception in different conditions has demonstrated that when a sensory circuit loses afferent signals that hyperactivity may bring about hallucinatory sensations. It would tend to account both for pain and for gustatory aggravations in burning mouth disorder (BMS).

Metallic or sharp tastes are viewed as symptomatic indications of an under animated gustatory circuit while under stimulated sensory circuitry shows burning sensations. The

cause of this proposed neuropathy is unknown.Studies focusing on trigeminal nerve alterations have found hypersensitivity and hyposensitivity as well as large and small fibres neuropathy [13, 14, 27, and 28]. Xerostomia in BMS is likely identified with neuropathy, as opposed to glandular dysfunction. In studies of burning mouth syndrome (BMS) patients in comparison to controls, no differences in salivary quantity or flow have been identified [29, 30].

BMS has been related with oral parafunctional propensities, for example, bruxism, holding, and tongue pushing. The bruxism and clenching are increased with anxiety, which is also associated with BMS. In spite of the fact that psychogenesis is no longer viewed as the essential cause, it mightexacerbate symptoms. Whether BMS has a neurologic abnormality in common with parafunctionalbehaviors has yet to be adequately investigated.

Burning mouth disorder (BMS) is additionally connected with a higher occurrence of gastrointestinal and urogenital illness, the noteworthiness of which is still unclear [31].

Clinical Features

A typical patient with BMS is postmenopausal woman of age 4th–6th decades with various medical comorbidities [32]. Clinical presentations may fluctuate as a few patient surgeries can be oligosymptomatic (pain and dysgeusia or xerostomia) or monosymptomatic (only pain) for the most part connected with dry mouth, sharp/metallic or modified taste [33]. The characteristics of BMS pain is chronic in nature with 4–6 months duration, burning or scalding type, sometimes itching sensation or numbness of the tongue, and other oral mucosal surfaces.[34]

The onset of pain can be either gradual and spontaneous or sudden and identified with a hastening occasion, for example, any dental procedure. Ordinarily, pain is confined to the tongue and some of the time including other mucosal surfaces likewise, for example, sense of taste, lip, buccal mucosa, and floor of the mouth. The pain will be continuous or intermittent, mild to moderate in intensity, restricted to the oral cavity and does not radiate to other regions of the face. The pain typically relieves on intake of food or liquids, which is in contrast to burning symptom in other diseases; in which the pain aggravates [35,36].

The pain is primarily two-sided and symmetrical on the front two-third of the tongue (71%–78%), followed by the dorsum and parallel outskirts of the tongue, the foremost piece of the

hard sense of taste, the labial mucosa, and gingiva, frequently showing up at a few areas [37]. A sensation of dry mouth with expanded thirst, taste changes, for example, an intense or metallic taste, loss of taste sensations.

Investigation

It is important to differentiate patients with primary BMS from those with symptoms caused by local or systemic factors (secondary BMS). The investigations for BMS are Haematological tests (CBC count, glucose levels, nutritional factors, autoimmune panel), oral cultures to confirm fungal, viral and fungal infections, salivary flow rates, patch tests for allergy testing, psychological or psychiatric assessment, salivary uptake scans, gastric reflux study, assessment of denture fit and function, Imaging techniques like MRI, CT scans and nuclear medicine[38].

Treatment

Studies on burning mouth syndrome (BMS) have focused more on cause than treatment. Currently, no definitive cure exists; many treatments have been tried with variable success. Before starting the treatment, it is important to know about nature of disease. Three treatment modalities are available. They are psychological therapy, topical medication, systemic medication. Psychological therapy includes cognitive behavioural therapy, group psychotherapy, electroconvulsive therapy, yoga, meditation and relaxation therapy. Topical prescription incorporates Clonazepam (1mg tablet to be broken down and hold in mouth), Lidocaine, Capsaicin, Benzydaminehydrochlorte, Doxepin cream, Lactoperoxidase oral flush, Sucralfate oral wash. Systemic medication includes Amitiptyline, Paroxetine, Amisulpride, Clonazepam,etc,.

The treatment options for BMS includes saliva replacement products, specific oral rinses or lidocaine, capsaicin, a pain reliever that comes from chili peppers, an anticonvulsant medication called clonazepam (Klonopin), certain antidepressants, medications that block nerve pain, cognitive behavioral therapy.

Clonazepam acts as an agonist of gamma-amino butyric acid (GABA) receptors. Systemic administration of clonazepam can result in inhibition of central nervous system functions producing an anticonvulsant action, light sedation, muscular relaxation, and tranquilizer effect. The topical use ofClonazepam can diminish the burning symptom without bringing

about the unfriendly impacts of its systemic use. Gremeau-Richard et al. [39] evaluated the efficacy of topical use ofClonazepam and found a greater decrease of pain score in Clonazepam-treated patients.

Ko et al and Amos et al. used a combined topical and systemic Clonazepam therapy. They found that mental status, beginning manifestation seriousness, and the nearness of xerostomia or potentially taste unsettling influence can fill in as result indicators ofClonazepam treatment for patients with BMS. They found that 80% of patients get more than a half diminishment in agony over the treatment time frame and 33% of the patients have finish torment determination, recommending that the consolidated topical and systemic Clonazepam organisation is a successful regimen for treatment of BMS [40,41].

Topical Clonazepam, a benzodiazepine, when applied as 0.5-1 mg 2-3 times day by day, acts by locally upsetting the neuropathologic component that underlies stomatodynia. Be that as it may, it diminishes the thickness or potentially ligand affinity towards benzodiazepine receptors. This, thusly, could cause unconstrained torment from the tissues concerned[42, 43]. Low measurements ofClonazepam dissolvable wafers accessible economically are better than tablets [44].

On systemic therapy, Clonazepam, a benzodiazepines, apply its impact by going about as a calming entrancing 0.25-2 mg measurements/day, 0.25 mg at sleep time, increment measurements by 0.25 each 4-7 days until oral burning is assuaged or reactions happen. As the measurements are expanded, pharmaceutical is taken in three isolated doses[42].

Mouthwash definitions have a few points of interest since the medication can be connected all the more consistently to the whole mouth, and a lovely flavour can be added to the mouthwash to improve consistence. Different medications as benzydamine hydrochloride [45] and capsaicin [46] have been tried as mouthwash details to treat BMS. Be that as it may, the outcomes did not turn out to be attractive as remedial choices. The utilization ofbenzydamine hydrochloride oral wash was strikingly not able to lessen the blazing sensation in BMS patients [45], while the capsaicin arrangement was successful however inadequately endured as 33% of the patients whined of extraordinary smoldering amid and for a couple of minutes after use of the capsaicin mouthwash [46].

Conclusion

Burning mouth syndrome remains a poorly understood common chronic oral-facial disorder which is difficult to diagnose and to treat. As BMS is associated with system symptoms, it is essential to manage the systemic cause. Medications are also used in the management of BMS but its effect is equal or less than the clonazepam. Most of the people are unaware about the burning mouth syndrome; many researches are needed to know about the effect of clonazepam in the management of BMS. This review study concluded that the use of the above topical, systemic and mouthwash aid in decreasing the amount of burning sensation associated with burning mouth syndrome produced in the oral cavity.

A Review on Emerging Treatment Modalities for Oral Submucous Fibrosis

R.Sharmila [1],Vivek Narayan[2],M. S. Nivedhitha[3],
Graduate Student[1], Senior Lecturer[2], Department of Oral Medicine and Radiology,
Professor and Head[3],Department of Conservative Dentistry and Endodontics,
Saveetha Dental College,Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Oral submucous fibrosis (OSMF) is a chronic insidious disease characterised by juxtaepithelial inflammation and fibroelastic changes in lamina propria leading to stiffness of the oral mucosa. OSMF is attributed to areca nut chewing which contains arecoline and arecaidine. Treatment of OSMF has always been challenging since the current treatment options do not provide a significant relief for the patient.

Oral submucous fibrosis (OSF) is a chronic, insidious disease that affects the lamina propria of the oral mucosa and, as the disease advances, it involves tissues deeper in the submucosa of the oral cavity with resulting loss of fibroelasticity. The disease manifests with blanching and stiffening of the oral mucosa leading to limitation in opening of the mouth.

Oral submucous fibrosis is a disease of the oral cavity and regarded as a potentially malignant disorder. Numerous treatment modalities ranging from various drugs to behavioral therapy have been tried with inconsistent results with varying degrees of success reflecting low predictability, requiring further evaluation and standardization. Novel treatment modality such as Hyperbaric oxygen therapy, Oxitard capsules , spirulina , Lycopene , pentoxyfilline, Turmeric, placental extracts advocated intralesionally along with oral drugs like carotenoids , hyaluronidase,betamethasone and dexamethasone.

A wide range of treatment including drug management, surgical therapy, and physiotherapy have been attempted till date, with varying degrees of benefit, but none have been able to cure this disease. This is mainly due to the fact that the etiology of the disease is not fully understood and the disease is progressive in nature.

Key Words:*Fibrosis, curcumin, dexamethasone, pentoxyfilline and placental extracts.*

Introduction

Oral submucous fibrosis (OSF) is a chronic, insidious disease that affects the lamina propria of the oral mucosa and, as the disease advances, it involves tissues deeper in the submucosa of the oral cavity with resulting loss of fibroelasticity. The disease manifests with blanching and stiffening of the oral mucosa leading to limitation in opening of the mouth. The presence of fibrous bands in lips, cheeks and soft palate is a hallmark of the disease. Oral submucous fibrosis predominantly affects South, South Asian and East Asian populations and is seen in India, Pakistan, Bangladesh, Nepal, Sri Lanka, southern parts of China, Taiwan, Melanesia and Micronesia and in the pacific islands.

Oral submucous fibrosis is a chronic disease of the oral cavity characterized by inflammation and progressive fibrosis of the submucosal tissues.

In 1952, Schwartz coined the term atrophicaidiopathica mucosa oris to describe an oral fibrosing disease he discovered in 5 Indian women from Kenya(1). Joshi subsequently coined the termed oral submucous fibrosis (OSMF) for the condition in 1953(2).

The pathogenesis of the disease is not well established, but the cause of oral submucous fibrosis is believed to be multifactoria. Factors include areca nut chewing, ingestion of chillies, genetic and immunologic processes, nutritional deficiencies, and other factors like areca nut component of betel quid plays a major role in the pathogenesis of oral submucous fibrosis(3,4,5).Commercially available products such as pan masala, guthka, and mawa have higher concentrations of areca nut per chew and appear to cause oral submucous fibrosis more rapidly than self-prepared conventional betel quid, which contains smaller amounts of areca nut.

Among the areca alkaloids such as arecoline, arecadine, guvacoline, guvacine, arecoline is the main agent responsible for fibroblast proliferation. Under the influence of slaked lime ($Ca(OH)_2$, arecoline get hydrolyzed to arecadine, which has pronounced effects on fibroblasts. Areca flavonoids tannins and catechins can cause increased fibrosis by forming a more stable and non soluble collagen structure by inhibiting collagenase enzyme activity. Studies have shown that there is 1.5 fold increase in collagen production by OSMF fibroblasts and with the progression of disease type 3 collagen is completely replaced by type 1 collagen which is more resistant to degradation. Also there has been an excess of alpha 1 (1) chains relative to alpha 2(1) chains, suggesting an alteration of collagen molecule during

the disease progression. Recently a study done on human buccal fibroblasts showed an increased expression of an insoluble cytoskeleton protein (57kDa) called vimentin in OSMF patients under arecoline influence. This protein vimentin is primarily expressed by mesenchymal cells, during cell growth, and tumorigenesis. Thus elevated vimentin expression stimulated by arecoline in OSMF may be suggestive of transformational changes in buccal fibroblasts of OSMF patients.

The commonly used treatment modalities for oral sub mucous fibrosis are placental extracts advocated intralesionally along with oral drugs like carotenoids.hyaluronidase,betamethasone and dexamethasone.

The emerging treatment modalities Are hyperbaric oxygen therapy. oxitard capsules, Lycopene, spirulina, pentoxyfilline and curcumin. Aim of the study is to provide an update on the various treatment modalities available for oral submucous fibrosis.

Hyperbaric Oxygen Therapy

Hyperbaric Medicine is the clinical specialty using pressure higher than local atmospheric pressure (>1atm) to treat diseases or injuries inside a hyperbaric chamber, to derive therapeutic benefit from breathing gases, usually oxygen. Hyperbaric Oxygen Therapy—"HYPER" means increased and "BARIC" means pressure.

Hyperbaric oxygen therapy is an well established therapy for decompression sickness ,a hazard of scuba diving ,other conditions include serious infections, bubbles of air in blood vessels and wounds that won't heal as a result of diabetes or radiation injury.

In OSMF increased fibrosis is due to imbalance between activation of fibroblasts and reduced degradation of collagen leading to increased fibrosis and trismus. Conconi et al., found that exposure to HBOT at 2.5 ATA for 120 min enhanced apoptosis of mouse fibroblast cell line (6).It also reduced cell proliferation when skin fibroblasts were cultured in a high-glucose medium at 2.5 ATA for 90 min on three consecutive days (7).

It may induce apoptosis of lymphocytes or/and decrease lymphocytic proliferation so as to keep fibroblasts from activating cytokines. HBOT at 1.0 or 2.5 ATA for 30 and 60 min enhanced 3T3/J2 fibroblast cell growth while at 2.5 ATA for 120 min, it exerted a pro apoptotic effect. HBOT may potentially contribute to the inhibition of fibroblasts by reducing IL-1b and TNF-α production. HBOT may be useful in the treatment for OSF by promoting fibroblast apoptosis and inhibiting fibroblast activation.

Indication of HBOT in Dentistry

1. Osteoradionecrosis
2. Post radiotherapy cases
3. Mandibular Osteomyelitis, Chronic Refractory Osteomyelitis
4. Periodontal disease
5. Infected Implants.

Contra Indications

1. Absolute

a. Untreated tension pneumothorax.

2. Relative

a. Upper respiratory tract infection.

b. Asymptomatic pulmonary lesions seen on chest x-ray.

c. History of thoracic or ear surgery.

d. Pregnancy.

e. Claustrophobia.

Adverse Effects

1. Middle ear barotrauma is the most common complication of HBOT therapy, with an incidence of about 2%. Inner ear barotrauma is a very rare occurrence.
2. Sinus squeeze is the second most common complication of HBOT therapy.
3. Tooth pain can occur during compression or decompression and this typically follows dental treatment that has created an air space under a dental filling.
4. Pulmonary oxygen toxicity can occur in patients if exposed for prolonged periods.
5. Fire is the most common fatal complication of hyperbaric oxygen therapy.

Oxitard Capsules and Lycopene

The formulation of the oxitard capsules contains the extracts of Mangiferaindica, Withania somnifera, Daucuscarota, Glycyrrhizaglabra, Vitisvinifera, powders of Emblica officinalis and Yashadabhasma; and oils of Triticum sativum. Mangiferaindica is shown to have antibiotic, anti-asthamatic, antiseptic, antiviral, hypotensive, anti-emetic properties. Withania somnifera provides overall health and wellness with its anti-stress, anti-anxiety, anti-

inflammatory, anti-convulsive and anti-arthritic properties. Daucuscarota acts as a good antiseptic as it is a rich source of vitamin A. Glycyrrhizaglabra normalizes the hoarseness in voice and has immunomodulatory and anti-inflammatory properties.
Vitis vinifera has anti-inflammatory, astringent and an effect to curb the burning sensation. Emblica officinalis is a rich source of vitamin C and is a potent antibiotic. Yashadabhasma contains zinc which plays a significant role in protein synthesis, cell division and wound healing. Triticum sativum is a rich source of minerals and has an antioxidant property .Oxitard has shown significant improvement in mouth opening, tongue protrusion, pain with the lesion, difficulty in swallowing and speech.

Lycopene is a powerful antioxidant obtained from tomatoes. It has been shown to inhibit various types of cancers and have potent benefits in oral pre malignant lesion where it has been shown to modulate dysplastic changes(8).The interest in the various mechanisms of action of this particular carotenoid is relatively recent and has the highest singlet oxygen quenching capacity with high capability of quenching other free radicals
Newer studies highlight the benefit of this oral nutritional supplement at a daily dose of 16 mg. Mouth opening in 2 treatment arms was statistically improved in patients with oral submucous fibrosis. This effect was slightly enhanced with the injection of intralesional betamethasone (two 1-mL ampules of 4 mg each) twice weekly, but the onset of effect was slightly delayed(9).

Lycopene is an potent antioxidant present in tomatoes and pink grapefruit. Like beta-carotene, Lycopene belongs to the family of carotenoids. As an antioxidant, it is about twice as powerful as beta-carotene. Review of the various safety studies has shown no adverse effects when administered in high doses even up to 3 g/kg/day of dietary or formulated lycopene. Presently, there is no consensus about the precise dosage of Lycopene when administered as a pure compound but various clinical trials suggest a dose ranging from 13 to 75 mg/kg/day. It warrants further studies in the future to help standardize an optimal dosage of the drug. In contrast to other management modalities for OSMF, Lycopene offers a noninvasive option that yields significant amelioration of the symptoms and signs of the disease as demonstrated by the improved maximal mouth (inter-incisal distance) opening up to 69.56%($P<0.05$). (10)The main focus of research has been the antioxidant property of lycopene.

However, it has also been shown to exert its effect via other mechanisms such as gene function regulation, gap junction communication, hormone and immune modulation, carcinogen metabolism, and modulation of metabolic pathways involving phase 2 drugmetabolizing enzymes. Lycopene is usually administered as a pill/ tablet per oral.This study was conducted to determine the frequency of positive and negative responses of lycopene in the treatment of oral submucous fibrosis.(11,12)

Lycopene is a carotenoid. They are natural pigments and antioxidant properties. Its profound benefits have been demonstrated with precancerous lesions such as leukoplakia.Mechanism of action lycopene shows abnormal fibroblasts inhibition in OSMF. It also regulates lymphocyte resistance to stress and suppresses infammatory response. This is the first line of therapy to OSMF. Lycopene exhibits the highest physical quenching rate constant with singlet oxygen.

Spirulina

Spirulina is blue green algae with rich natural source of proteins, carotenoids and other micronutrients (13). It has been primarily assessed in treating leukoplakia with promising results. The chemopreventive capacity to reverse precancerous lesions of spirulina is attributed to the antioxidant property with high amount of beta carotene and superoxide dismutase.Highly significant results were obtained with all three parameters namely burning sensation, mouth opening and tongue protrusion.

Recently, Shetty et al (14) have delineated the role of Spirulina as an adjuvant therapy in the management of OSMF. They conducted an interventional study on 40 cases of OSMF. The treatment groups were divided into two of twenty each, with the first group receiving Spirulina 500 mg BID and biweekly intralesional injections of steroid Betamethasone 4 mg/mL for a period of 3 months and the second group receiving placebo capsules BID and biweekly intralesional steroid injection of Betamethasone 4 mg/mL for 3 months. They found that Spirulina was effective in alleviating the burning sensation in patients probably due to its beta-carotene, phenolic acid, tocopherol, and micronutrient content. Additionally, they stated that use of beta-carotene systemically and topically helps in improving the epithelial integrity

and brings about redifferentiation of dysplastic epithelium. They suggested that Spirulina can be advocated as an adjuvant therapy in the early treatment of OSMF.

Similarly, Mulk et al (15) studied the effect of Spirulina (500 mg) and Pentoxifylline (400 mg). Each group (20 cases of OSMF per group) used the individual formulations twice daily for a period of 4 months. They obtained significant results in relation to burning sensation, mouth opening, and tongue protrusion. Efficacy wise, however, they were similar in respect to mouth opening and protrusion of the tongue. Although even with this study, the reduction in burning sensation was more in the Spirulina group. Further, they highlighted that no adverse effects were noted in the patients using Spirulina.

Another study, using two natural antioxidants was performed by Patil et al. (16) They studied 42 cases of OSMF by dividing them equally in two groups, first the Spirulina group (500 mg Spirulina in two divided doses for 3 months) and second the aloe vera group (5 mg gel for topical application thrice daily for 3 months) with an additional follow-up period of 2 months. In concordance with the Mulk study, they found no side effects in both the study groups. Both the study drugs brought about a similar reduction in burning sensation. Spirulina brought about significant clinical improvements in mouth opening and ulcers/erosion/vesicles. They put forth that Spirulina brings about better treatment outcomes as compared to aloe gel.

Similarly, Patil et al (17) also evaluated the efficacy of Spirulina and lycopene in 68 OSMF patients. They administered two divided doses of 500 mg of Spirulina in group I for a period of 3 months and two divided doses of lycopene 4 mg for the same time period. They observed that lycopene brought about improvements in the clinical symptoms, such as mouth opening, whereas Spirulina improved ulcers/erosion/vesicles in the OSMF patients. They also observed similar effects in terms of alleviation of pain and burning sensation and thus put forth that both the drugs can act as useful modality of treatment in cases of OSMF.

Pentoxyfilline

Trental (pentoxifylline) is a xanthine derivative. It belongs to a group of vasoactive drugs which improve peripheral blood flow and thus enhance peripheral tissue oxygenation. The mechanism by which Trental achieves this effect has not been determined, but it is likely that the following factors are involved:

- Trental, as with other xanthine derivatives, relaxes certain smooth muscles including those of the peripheral vessels, thus causing vasodilatation or preventing spasm. This action, however, may have a limited role in patients with chronic obstructive arterial disease when peripheral vessels are already maximally dilated.
- Trental improves flexibility of red blood cells. This increase in the flexibility of red blood cells probably contributes to the improvement of the ability of blood to flow through peripheral vessels (haemorheologic action). This property was seen during in vitro and in vivo experiments with Trental but the correlation between it and the clinical improvement of patients with peripheral vascular diseases has not been determined.
- Trental promotes platelet deaggregation.Improvement of red blood cell flexibility and platelet deaggregation contribute to the decrease in blood viscosity(18).

Pentoxifylline is a tri substituted methyl xanthine derivative, with numerous biologic activities. It is termed as a "rheologic modifier." It improves microcirculation and decreases aggregation of platelet as well as granulocyte adhesion. It increases leukocyte deformability as well as inhibits neutrophil adhesion and activation. It increases production of prostaglandin E2 and prostaglandin I2 by vascular epithelium and maintain cellular integrity and homeostasis after acute injury. In addition, it causes degranulation of neutrophils, promotes natural killer cell activity and inhibits T-cell and B-cell activation. Pentoxifylline has also shown a direct effect on inhibiting burn scar fibroblasts. Haddad *et al*. (19) treated 34 radiation-induced superficial fibrotic lesions of the skin with pentoxifylline and Vitamin E for 3 months and reported a significant effect in the improvement of radiation-induced fibrosis. It has been postulated that pentoxifylline may be a valuable drug for reducing burn scar contractures. It has been shown to be effective in various medical disorders such as stroke, aphthous stomatitis, peripheral arterial occlusion, cerebrovascular insufficiency and pre tibialmyxedema.

Vasodilators like pentoxifylline have vasodilating properties and hampered mucosal vascularity in OSMF could be increased by the use of pentoxifylline. Pentoxifylline sup-presses leucocyte function and alters broblast physiology and stimulates brinolysis. In one study the effect of pentoxyfilline was studied on the clinical and pathologic course of OSMF. This investigation was conducted as a randomized clinical trial incorporating a control group in comparison to pentoxifylline test cases The authors concluded that pentoxifylline can be

used as an adjunct therapy in the management of oral submucous fibrosis. In another study Pentoxifylline 400mg for a period of 7 months, showed an improvement in total signs and symptoms of OSMF. No significant side effects were observed.

The use of Trental (pentoxifylline) is contraindicated in:

- Patients who are hypersensitive to pentoxifylline or other xanthines such as caffeine, theophylline and theobromine or to any ingredient in the formulation or component of the container.
- Patients with acute myocardial infarction.
- Patients with severe coronary artery disease when, in the physician's judgement, myocardial stimulation might prove harmful;
- Patients with hemorrhage (e.g. extensive retinal bleeding) or at risk of increased bleeding;
- Patients with peptic ulcers.

In a pilot study, 14 test subjects with advanced oral submucous fibrosis given pentoxifylline at 400 mg 3 times daily were compared to 15 age- and sex-matched diseased control subjects. Statistical improvement was noted in all measures of objective (mouth opening, tongue protrusion, and relief from fibrotic bands) and subjective (intolerance to spices, burning sensation of mouth, tinnitus, difficulty in swallowing, and difficulty in speech) symptoms over a 7-month period(20).

In another study they showed a significant ($P < 0.05$) improvement in mouth opening, tongue protrusion, difficulty in speech and swallowing, pain associated with the lesion and burning sensation. Most side effects with pentoxifylline involve the central nervous system and the gastro-intestinal tract. The most common gastro-intestinal problems include dyspepsis, nausea and/or vomiting. A few may also report bloating, flatus and bleeding. The side effects related to the central nervous system include dizziness, headache, tremor, anxiety and confusion. 8 patients in the Group A experienced nausea, bloating of the stomach, dyspepsia and anxiety. The symptoms were mild in nature and resolved within a few days, without the need for cessation of the drug. This was similar to the findings of Rajendran *et al*. and Mehrotra *et al*. (21,22) The side effects are said to be dose related and can be minimized with reduction of dose.

Curcumin

Curcumin is a nonnutritive, nontoxic polyphenol natural product found in turmeric, a spice that has been used for centuries in India and elsewhere as an herbal medicinal treatment of wounds, jaundice, and rheumatoid arthritis. Sharma (1976), Ruby et al. (1995), and Sugiyama et al. (1996) studied the antioxidative properties of curcumin and its three derivatives (demethoxy curcumin, bisdemethoxy curcumin, and diacetyl curcumin). The authors demonstrated that these substances provide a protection of hemoglobin from oxidation at a concentration as low as 0.08 mM, except the diacetyl curcumin, which has little effect in the inhibition of nitrite-induced oxidation of hemoglobin. The effect of curcumin on lipid peroxide (LPO) has also been studied in various models by several authors. Curcumin is a good antioxidant and inhibits LPO in rat liver microsomes, erythrocyte membranes, and brain homogenates. The LPO has a main role in the inflammation, in heart diseases, and in cancer.

The use of curcumin in treating OSF in humans. Curcumin inhibits proliferation, disrupts the cell cycle, induces apoptosis, and decreases the expression levels of type I and III collagen; and it clearly demonstrates curcumin'santifibrotic potential in vitro. Administration of curcumin powder offers protection benzopyrene induced increase in micro nuclei in circulating lymphocytes and its excellent scavenger of free radical in vitro. (23,24) Curcumin oil and curcumin leoresin both act synergistically in vivo to offer protection against DNA damage. (25). Curcumin modulates the inflammatory response by.

a) Down-regulating the activity of cyclooxygenase-2 (COX-2), lipoxygenase, and inducible nitric oxide synthase (iNOS) enzymes.

b) Inhibits the production of the inflammatory cytokines, tumor necrosis factor-alpha (TNF-alpha), interleukin (IL) −1, −2, −6, −8, and −12, monocyte chemoattractant protein (MCP), and migration inhibitory protein.

Agarwal N et al. (26) conducted a study to check the efficacy of turmeric in 30 OSMF patients. An improvement in mouth opening and burning sensation was noticed. It was hypothesized that curcumin exerts anti-inflammatory activity by inhibiting a number of different molecules that participates in the process of inflammation. They also exhibit fibrinolytic property due to its ability to inhibit lipid peroxidation and check cellular proliferation, thereby reducing the rate of collagen synthesis.

Another study conducted by Deepa DA et al. (27) to evaluate the efficacy of curcumin and turmeric dispensed in two forms namely curcumin capsules and turmeric oil in 48 patients with OSMF. Statistically significant improvement was observed in the clinical signs and symptoms of patients treated with curcumin and turmeric oil. It showed anti-inflammatory action and fibrinolytic properties.

Yadav M et al. (28) conducted a study for comparison of curcumin with intralesional steroid injections in osmf patients. Improvement of burning sensation, interincisal distance and tongue protrusion was evaluated on a weekly basis and it was found that there was marked improvement in burning sensation, intreincisal distance and tongue protrusion.

BalwantRai(29) conducted a study to know the possible mechanism of action for curcumin in pre-cancerous lesions and condition based on serum and salivary markers of oxidative stress. It was found that curcumin mediates its anti pre-cancer activities by increasing levels of vitamins C and E and preventing lipid peroxidation and DNA damage. This could be due to curcumin-induced production of vitamins C and E and preventive DNA damage by decreasing the oxidation stress. This suggests that the anti-precancerous effects of curcumin are mediated through pro-oxidant and anti-oxidant pathways.

Zhang SS et al. (30) showed in their study that curcumin inhibits proliferation, disrupts the cell cycle, induces apoptosis, and decreases the expression levels of type I and III collagen; confirming its potential therapeutic value in OSMF patient.

Another study showed that use of curcumin in osmf significantly reduce connective tissue growth factor which is associated with the onset and progression of OSMF. (31)

Various studies have been conducted over a period of time showing the efficacy of curcumin in treating the osmf patients. Constant use of curcumin showed marked improvement in osmf patients due to its pharmacological activities. Further studies need to be carried out to prove the efficiency of curcumin in treating OSMF.

Conclusion

Our review of the literature for treatment of OSMF yielded a spectrum of treatment modalities to manage OSMF. Numerous treatment modalities that have been implicated to cure the disease are the use of corticosteroids, hyaluronidase, placentrix, hyperbaric oxygen

therapy, oxitardcapsules ,lycopene, spirulina, pentoxyfilline and curcumin. Though, till date, there is no single method which can be used as the definitive treatment modality for OSMF. Recent literature proves that the combination of drugs produce effective results in the management of this disease. A more extensive clinical trials involving a greater number of cases and including more parameters are necessary to come to a conclusion about a particular modality in the management of OSMF.

Abstract

Diabetes is a disorder of metabolism. It results in too much sugar in the blood, or high blood glucose. It involves problems with the hormone insulin. Normally pancreas is the organ responsible for releasing insulin to help our body store and use the sugar and fat from the food we consume. Insulin causes cells to take in sugar to use as energy or to store as fat. This causes blood sugar levels to go back down. Diabetes can occur when the pancreas produces very little or no insulin, or when the body does not respond appropriately to insulin. Thus it is important to treat diabetes on time to avoid consequences.

Key Words: *Diabetes, Hyperglycaemia, diabetes type 1, diabetes type 2*

Introduction

Diabetes is a disorder of metabolism. It results in too much sugar in the blood, or high blood glucose. It involves problems with the hormone insulin. Normally pancreas is the organ responsible for releasing insulin to help our body store and use the sugar and fat from the food we consume. Insulin is responsible for converting the sugar into energy or fat. Thus helping in the blood sugar to become normal. So this if there is any problem with the production of insulin or if the body does not respond to the insulin; it leads to Diabetes. There are 3 types of Diabetes: Type 1, Type 2 and Gestational diabetes [1].

Type 1 diabetes: It is when our immune system destroys the beta cells of pancreas which is responsible for the production of insulin, leading to no insulin production or less insulin production. This results in higher sugar level in blood since there is no insulin to convert them to energy.

Type 2 diabetes:It is when the production of insulin is normal but our body does not respond to the insulin, that is, the cell in our body becomes resistant to insulin. Insulin resistant happens primarily in fat, liver, and muscle cell.

Gestational Diabetes: It occurs in pregnant women, since the placenta produces hormones which increase the blood sugar level.

Signs and Symptoms of Diabetes

The most common diabetes symptoms include unusual weight gain, unusual weight loss, fatigue, non-healing wounds or cuts, sexual dysfunction in males, numbness and tingling sensation in hands and feet.

Classic symptoms of diabetes arepolyuria (increased urination),polydipsia (increased thirst), andpolyphagia (increased hunger) [1].

The major long-term complications of diabetes are that it causes damage to blood vessels. Diabetes increases the risk of cardiovascular disease [2].

Among patients with diabetes, 15% of the patients develop a foot ulcer, and 12-24% of individuals with a foot ulcer require amputation [3].

Diabetic Foot Ulcer

Diabetic foot ulcer is one of the major complications of diabetes mellitus. Diabetes mellitus is a metabolic disorder which slows down the wound healing process. Many studies show a

prolonged inflammatory phase in diabetic wounds, which causes a delay in the formation of granulation tissue and reduction in wound tensile strength [1]

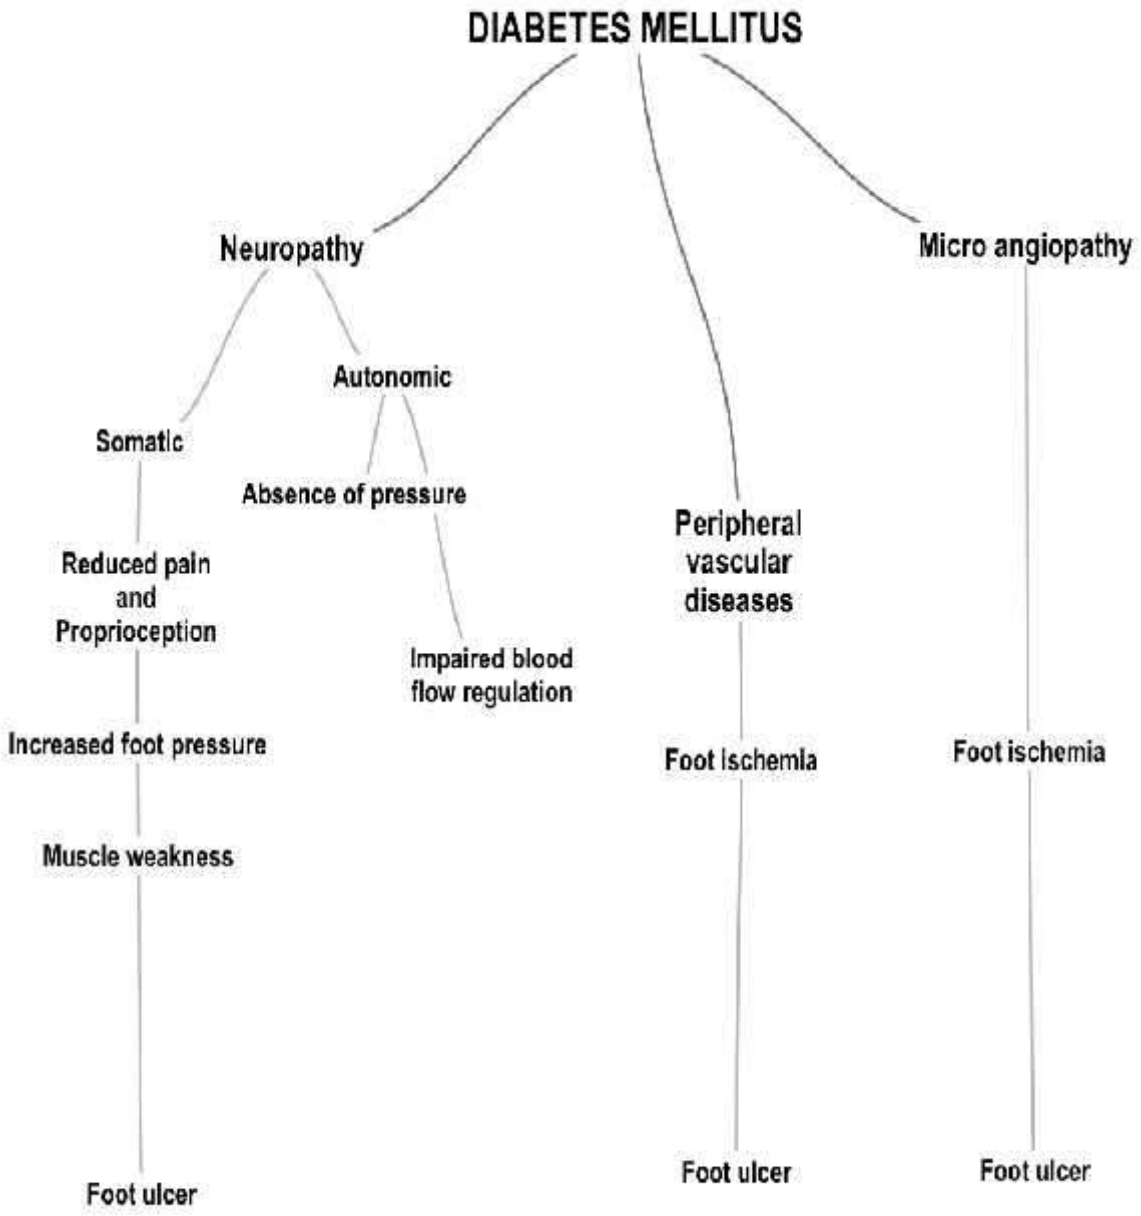
An ulcer is defined as a break in the skin surface that may to involve the subcutaneous tissues or even deeper to the level of muscle or bone[2]. Ulcers form due to a combination of factors, such as increased body weight, numbness of foot, poor circulation, irritation, and trauma, as well as duration of diabetes [3]. Ulcers often progress to infections of the surrounding tissue, osteomyelitis, and amputation [4, 5].

Patients who have diabetes for many years can develop neuropathy. Neuropathy is a reduced or complete lack of ability to feel pain in the feet caused because of never damage due to elevated blood glucose level for a long period of time. The nerve damage often can occur without pain, and one may not even be aware of the problem [6]. This canbe one of the causes leading to foot ulcer.If the foot ulcer gets infected then it cannot be cured by medication, in such cases Amputation is the only choice. Amputation refers to surgical removal of the ulcer.

Pathophysiology

Ulcer in diabetics can be because of three reasons Neuropathy, Peripheral vascular diseases and Micro angiopathy. Neuropathy can be of two types somatic and autonomic. In case of somatic the limbs loses its sense of pain and proprioception, which leads to increased foot pressure. Increase in foot pressure for a prolonged period of time causes muscle weakness which ultimately leads to foot ulcer. In case of autonomic the cause of foot ulcer will be because of impaired blood flow regulation.

Peripheral vascular diseases and micro angiopathy causes foot ischemia. Ischemic foot refers to a lack of normal arterial blood flow from the heart to the feet [7]. That is there is meaning there is not enough blood reaching the foot to provide the oxygen and nutrient needs required for the cells to continue to function.In case of peripheral vascular diseases the blood vessels are narrow and there is reduced blood supply to legs and feet. It also causes nerve damage this leads to lose of the feel of pain. In absence of pain the patient won’t realise the wound or ulcer in the foot and will continue putting pressure on the affected area, this makes the affected area worse and the presenting ulcer or infection will spread to the bone. Once the infection spreads to the bone, the damage cannot be reversed and it leaves us with one option which is amputation. The most common site of amputations are toes, feet and lower legs.



Flow chart 1: Pathophysiology of Foot Ulcer

:

Flow Chart 2: Pathophysiology of Foot Ulcer

Classification of Foot Ulcer

Foot ulcer in diabetic patients can be classified based on depth of ulcer penetration, the presence of wound infection, and the presence of clinical signs of lower-extremity ischemia [8,9].

Stages

Stage A: No infection or ischemia

Stage B: Infection present

Stage C: Ischemia present

Stage D: Infection and ischemia present

Grading

Grade 0: Epithelialized wound

Grade 1: Superficial wound

Grade 2: Wound penetrates to tendon or capsule

Grade 3: Wound penetrates to bone or joint

Management and Treatment

Healing is the primary goal to be achieved in the treatment of foot ulcer in diabetic patients[5].The faster the healing, the less chance for an infection. Management of foot ulcer also depends on the severity and grading of foot ulcer. Lesser the grade and stage faster and easier the management. The risk of ulceration and limb amputation in people with diabetes can be improved by routine preventive podiatric care, appropriate shoes, and patient education[10]

The initiating injury may be from acute mechanical or thermal trauma or from repetitively or continuously applied mechanical stress[11].

Treatment of diabetic foot ulcer includes

- Debridement
- Wound coverage
- Platelet-derived growth factors (PDGF)
- Enzymatic debridement
- Miscellaneous topical agents
- Hydrotherapy
- Treatment of Charcot foot
- Vacuum-assisted closure
- Surgical Care
- Revisional surgery
- Vascular reconstruction
- Hyperbaric Oxygen Treatment

Debridement

Debridement is defined as the removal of damaged, dead and /or infected tissues in order to improve healing process. Removal may be surgical, mechanical, chemical, and autolytic [12].

Wound coverage

Optimal wound coverage requires wet-to-damp dressings, which support autolytic debridement, absorb exudate, and protect surrounding healthy skin [13]. For wounds that are neither very dry nor highly exudative a polyvinyl film dressing which is semi permeable to oxygen and moisture and impermeable to bacteria can be used [14].

Platelet-Derived Growth Factors (PDGF)

PDGF when applied topically on the wound promoted the healing. Becaplermin gel 0.01% is a recombinant PDGF which is produced through genetic engineering is approved by the US Food and Drug Administration (FDA) to promote healing of diabetic foot ulcers [15]

Enzymatic Debridement

Collagen comprises a significant fraction of the necrotic soft tissues in chronic wounds; the enzyme collagenase, derived from fermentation of Clostridium histolyticum, helps remove nonviable tissue from the surface of wounds [16]. But is not a substitute for an initial surgical excision of a grossly necrotic wound.

Miscellaneous Topical Agents

Various other topical agents that have been used for wound management include sugar, antacids, and vitamin A and D ointment [12, 15].

Hydrotherapy

Intractable, infected, cavity wounds sometimes improve with hydrotherapy using saline pulse lavage under pressure [17]

Treatment of Charcot Foot

Charcot foot is a condition causing weakening of the bones in the foot that can occur in people who have significant nerve damage (neuropathy).

Charcot foot is treated initially with immobilisation using special shoes or braces but eventually may require podiatric surgery such as osteotomy and arthrodesis[18]

Vacuum-Assisted Closure

Clean but non-healing deep cavity wounds may respond to repeated treatments by application of negative pressure under an occlusive wound dressing (vacuum-assisted closure [VAC] [19].

Surgical Management

Debridement of the dead and infected tissues from the ulceration and curettage of the underlying osteomyelitis bone are under the surgical management [20].All patients harbouring diabetic foot ulcers should be evaluated by a qualified vascular surgeon or podiatric surgeon who will consider debridement, revisional surgery on bony architecture, vascular reconstruction, and options for soft tissue coverage before any surgical procedures [11, 20].

Revisional Surgery

Revisional surgery for bony architecture may be required to remove pressure points [21]. Such intervention includes resection of metatarsal heads or ostectomy.

Hyperbaric Oxygen Treatment

Hyperbaric oxygen therapy is used rarely and is certainly not a substitute for revascularization [22] .In the presence of an intractable wound and associated non-correctible ischemic arterial disease, hyperbaric oxygen therapy may be beneficial [23]

GlycaemiaControl

The Diabetes Control and Complications Trial, performed by the Diabetes Control and Complications Trial ResearchGroup,studiedthe effect of intensive treatment of diabetes on the development and progression of long-term complications in insulin-dependent diabetes mellitus in the year 1993 [24]. In this it was found that uncontrolled hyperglycaemia is related to diabetic micro vascular complications and if it’s under control then the complications of diabetes including neuropathy and nephropathy can be prevented [24].

Measures for Prevention of Diabetic Ulcers

The risk of ulceration and limb amputation in people with diabetes can be improved by routine preventive podiatric care, appropriate shoes, and patient education [20].Diabetic clinics should screen all patients for altered sensation and peripheral vascular disease.

Cigarette smoking should be stopped, and hypertension and hyperlipidemia should be controlled [5].

Of diabetic foot ulcers, 85% are estimated to be preventable with appropriate preventive medicine, including the following [25]

- Daily foot inspection
- Gentle soap and water cleansing
- Application of skin moisturiser
- Inspection of the shoes to ensure good support and fit
- Minor wounds require prompt medical evaluation and treatment.
- Prophylactic podiatric surgery to correct high-risk foot deformities may be indicated.
- Avoid hot soaks, heating pads, and irritating topical agents.

Abstract

ADAMTS13, a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13, is a metalloprotease that cleaves von Willebrand factor (VWF). There is considerable evidence that VWF levels increase and ADAMTS13 levels decrease in ST-elevation myocardial infarction (STEMI) patients. It is unclear whether this contributes to no re- flow, infarct size, and intramyocardial haemorrhage (IMH).The main aim of this review article is to know in detail about ADAMTS-13 in myocardial infarction.The objective of this article is to assess ADAMTS-13 and its role in myocardial infarction in all aspects and to know the opinions of different authors.The present study was to know about ADAMTS-13 in detail. Various articles from different authors were collected and summed up as a review article so that ADAMTS-13 and its key role in myocardial infarction is known elaborately in all aspects. We have demonstrated that the spacer domain particularly the exosite 3 which is the major target of anti-ADAMTS13 autoantibodies in patients with acquired TTP. Thus the autoantibody which binds to this region is expected to block the substrate binding and inhibit its proteolytic activity of ADAMTS13. Replacement of residues in exosite 3 with alanine is expected to completely abolish anti-ADAMTS13 IgG binding but this also significantly impairs the proteolytic activity of ADAMTS13, which render these mutants which are useless for therapy. Tremendous progress has been made in the past decade towards our understandings of the bio-synthesis, the structure-function relationship and co-factor – dependant regulation of ADAMTS13 function. These advances provide invaluable information which concerns the mechanisms of TTP and other atherothrombotic disorders as well as its inflammatory diseases. Hence novel diagnostic tools and therapeutics may be developed for managing these potentially fatal diseases.

Key Words:*ADAMTS-13, myocardial infarction, von willebrand factor, haemostasis, thrombosis.*

Introduction

In haemostasis and thrombosis, von willebrandfactor(VWF) plays an important role. It acts both as a cofactor in platelet adhesion and aggregation and also acts as a circulating carrier protein for coagulation factor VIII[1].It involves three major steps: (1) Vasoconstriction, (2) formation of a platelet plug, and (3) coagulation (secondary hemostasis). The first step is an immediate constriction of damaged blood vessels caused by vasoconstrictive paracrine released by the endothelium which results in a temporary decrease in blood flow within the injured vessel [41]. Meta analyses of prospective studies have suggested that increasing circulating vwf levels are associated with the risk of producing increased risk of coronary heart disease (CHD) [2]. The molecular weight or multimeric composition of VWF is an important determinant which plays the role of platelet – tethering. This is modulated by a disintegrin and metalloproteinase with a thrombospondin(type I) motif, and member 13 which is nothing but ADAMTS-13. ADAMTS-13 cleaves the VWF A2 domain which reduces its molecular weight and consequently also its platelet tethering function[3].Now the deficiency of ADAMTS-13 promotes VWF-induced platelet aggregation. This can result in thrombotic thrombocytopenic purpura [4]. It has therefore being suggested that circulating levels of ADAMTS-13 may influence circulating levels of VWF and/or its function. Therefore it influences the risk of thrombotic events such as myocardial infarction (MI) in the general population.Myocardial infarction (MI), occurs when blood flow stops to part of the heart causing damage to the heart muscle is commonly known as a heart attack. Coronary artery disease is the main cause of Most MIs. Risk factors include High blood pressure, smoking, diabetes, lack of exercise, obesity, high blood cholesterol, poor diet, and excessive alcohol, among others.

Adamts-13 with VWF Antigen

Both ADAMTS-13 and VWF antigen are risk factors for non-fatal coronary event which is nothing but myocardial infarction along with the effects that are in opposite directions which are clearly independent of each other. VWF has effects which are largely unaffected by other cardio vascular disease risk factors, unlike ADAMTS-13 which appears to have some sort of effects which are masked by co-existence of other risk factors [4]. After the largest set of cardio vascular risk factors have been adjusted, an additional 1 SD of VWF (about 60 IU $dL^{-}1$) is expected to raise the risk of myocardial infarction by about 35%. This is similar to

amount (27%) where the risk is lowered after increasing ADAMTS-13 by 1 SD. The association of VWF ANTIGEN with myocardial infarction is consistent with the recent meta-analysis of prospective studies of Coronary Heart Disease (CHD) [3].

Adamts-13 and Potential Human Diseases ADAMTS-13, first identified and cloned in 2001 is a member of the ADAMTS(A Disintegrin And Metalloprotease with ThromboSpondin type I repeats family) [1,2]. This ADAMTS-13 cleaves a large polymeric adhesion protein called as Von Willebrand Factor (VWF). This VWF is synthesised in vascular endothelial cells and megakaryocytes [3, 4]. This newly synthesised VWF is stored in intra cellular organelles. Weibel-Palade bodies in endothelial cells and alfa-granules in megakaryocytes and platelets [5].

VWF is released basically upon physiological or pathological stimulation and this forms an ultra-long or ultra-large (UL) “string-like” structure on the endothelial surface [6]. These string-like structures are hyper-active in recruiting circulating platelets to the site of endothelial activation and/or injury. Plasma ADAMTS-13 is primarily synthesised and released from the hepatic stellate cells and endothelial cells [7]. This binds and cleaves cell bound UL-VWF strings at the Tyr1605_Met1606 bond, thereby eliminating the UL-VWF strings from the endothelial surface, thus resulting in the fragmentation of VWF strings[6,7]. In addition to this ADAMTS-13 cleaves UL or large VWF in solution after being exposed to high fluid shear stress. This is already seen in micro circulation or at the site of narrow vessels and thrombus formation after injury [8].

Arterial shear stress induces conformational changes in soluble multimericVWF [9]. This becomes accessible by ADAMTS-13 for cleavage. This conformational changes can also be induced in vitro by an addition of denaturant such as urea or guanideine-HCl [10] is the molecular basis of various bio-chemical assays for plasma ADAMTS-13 activity.Due to severe deficiency of plasma ADAMTS-13 activity, there occurs an inability to cleave cell bound and soluble UL or large VWF in circulation. This results in the persistence of hyperactive UL-VWF on endothelial cells and in circulating blood, which leads to excessive platelet aggregation and disseminated VWF/platelet rich thrombus formation, which is the characteristic feature of thrombotic thrombocytopenic purpura [2].

Biosynthesis and Secretion of Adamts-13

Primarily ADAMTS-13, is synthesised in the liver of humans, mice and rats[8].The m-RNA, encoding the full length of ADAMTS-13, is detected only in the liver by Northern blotting analysis[3].But a truncated form of ADAMTS-13 m-RNA, is found in other tissues such as placenta and skeletal muscle by the same method[4].Fragments of ADAMTS-13 m-RNA, are amplified in many tissues including kidneys, spleen, thymus, prostate, pancreas, testis, ovary, small intestine, colon, and peripheral blood leukocytes[7]. ADAMTS-13 IS localised to cells stellate cells residing in the interstitial area of human, mouse, and rat livers. ADAMTS-13 m-RNA and protein have also been detected in vascular endothelial cells in vitro and in vivo[6].

The function of ADAMTS-13, which is synthesised in the endothelium, is not completely understood. When the endothelial cells produce trace amounts of ADAMTS-13 in culture, their massive surface coverage suggests a substantial contribution of endothelium derived ADAMTS-13 to plasma ADAMTS-13 [5].In addition to this ADAMTS-13 is released from endothelial cells may cleave the newly formed UL-VWF strings on the cell surface providing an additional mechanism to maintain a VWF-free surface[6].It has been demonstrated that ADAMTS-13 has either pro angiogenic or anti angiogenic effects depending on the cellular environment.

On one hand, when undergoing the treatment of HUVECs with recombinant ADAMTS-13 results in a dramatically increasedtube formation and cell migration which can be suggested with enhanced angiogenesis. While on the other hand, when vascular endothelial growth factor(VEGF) is present in the culture medium, the VEGF induced angiogenic activity is inhibited by ADAMTS-13 [8]. This anti-angiogenic effect is reversed by pre incubation of ADAMTS-13 with a polyclonal antibody against the C-terminal TSP1 5-7 repeats of ADAMTS-13 is undergone, which suggests a role of TSP1 repeats in mediating the pro and anti angiogenic effects [6].

Structure-Function Relationship of Adamts-13

ADAMTS-13 shares similar domain structure as compared with other ADAMTS family proteases, which comprises of a single peptide, a propeptide, a

metalloprotease,adisintegrinlike domain, first thrombospondin type 1 repeat(TSP1), Cys-rich and spacer domains. The more distal C-terminus contains seven additional TSP1 repeats and two CUB domains.

The function of each domain of ADAMTS-13 in its biosynthesis, secretion, and its proteolytic activity has been studied thoroughly in the recent years [4].When compared to propeptides of other ADAMTS or ADAM family proteases,the ADAMTS-13 propeptide is exceptionally short(only app.41 residues).[7]. While the propeptides of other ADAMTS proteases function as molecular chaperones to assist protein folding and maintain the latency of the proteases by a mechanism called “cysteine-switch”, the ADAMTS-13, propeptide is not required for its secretion and activation [9].Recombinant human ADAMTS-13 expressed in the cells with or without a propeptide secretes normally and is able to cleave VWF substrates with similar efficacy[8].

The metalloprotease domain of ADAMTS-13 has the expected hall marks of the reprolysin or adamalysin family of metalloprotease. This includes three histidine residues which co-ordinate the essential Zn2+ion in the sequence **H**E*XX***H***XX**G*XX***H**D. In addition, three putative Ca2+ -binding sites have been postulated based on modelling the metalloprotease domain of ADAMTS4 and ADAMTS5 [12]. The first putative Ca2+ bindingsite which comprises of amino acid residues Glu83, ASP173, Cys281 and Asp284 that are broadly conserved among ADAMTS and other metalloprotease and this appear to mediate low affinity of Ca2+ -binding.

The second putative Ca2+ -binding site consist of residues Glu164 and Asp166 in conjunction with oneor more of residues Asn162, Asp165 and Asp168[14]. Mutations at the second putative site have no effect on the Ca2+ -dependent ADAMTS13 activity. The third site is predicted to include residues Asp187 and Glu212 in conjunction with Asp182 or Glu184. Mutations at this site dramatically reduce Ca2+ -induced ADAMTS13 activity, suggesting that the residues at the third site play an important role in high-affinity Ca2+ binding and proteolytic activity[14].Replacement of the TCS domains of ADAMTS5 which is a closely related member of ADAMTS proteases, with those of ADAMTS13 alters with ADAMTS5 substrates specificity[8].

ADAMTS5 is not known to cleave VWF but a chimeric variant which consists of the metalloprotease and this integrin domain like of ADAMTS5 (MD5) and three non-catalytic TCS domains of ADAMTS13 (TCS13) (MD5/TCS13) is able to cleave the Glu1615-Ile1616 bond of VWF domain A2 in peptide substrates or VWF multimers that has been sheared [10]. However this cleavage site is no longer at the Tyr1605-Met1606 bond [11]. This further confirms the critical role of each of the non-catalytic domains of ADAMTS13 in substrates specificity[3].

Materials and Methods

The present study was to know about ADAMTS-13 and myocardial infarction in detail. Various articles from different authors were collected and summed up as a review article so that ADAMTS-13 is known elaborately in all aspects. The articles were collected by manual searching of the references of the relevant retrieved articles, peer-reviewed medicine journals, and gray literature. Search terms included ADAMTS-13, MYOCARDIAL INFARCTION, HAEMOSTASIS, THROMBOSIS.. Non-English articles were excluded from the review in the study-selection stage. Data extraction and evaluation of primary studies were performed independently by 2 reviewers.

Discussion

In up to 40% of ST-elevation myocardial infarction (STEMI) patients, imperfections in myocardial blood flow are observed despite reperfusion at the epicardiallevel[21]. This phenomenon, also referred to as no reflow, is occasionally observed angiographically directly after percutaneous coronary intervention (PCI). In a majority of cases, it is established several days later by cardiac magnetic resonance (CMR) as a hypoenhanced area within the hyperenhanced infarcted myocardium.[22,23] Both angiographic no reflow and CMR-defined no reflow are related to increased cardiac failure and death.[24-26]

Various mechanisms for this phenomenon have been proposed including tissue oedema, distal embolization of atherosclerotic debris, and also local microthrombi causing occlusion of capillaries leading to larger infarct size and worse outcome.[27] Recently, it was shown that CMR-defined no reflow actually contains intramyocardial haemorrhage (IMH) and

complete microvascular destruction.[28-30] von Willebrand factor (VWF) is an important factor in primary haemostasis. It attracts platelets to damaged endothelium, causing platelet adhesion; and it thereby initiates and stabilizes platelet aggregation.

VWF is released from endothelium during vessel injury in the form of ultra-large VWF multimers, which contain several platelet binding sites and are therefore more prothrombotic. ADAMTS13, a disintegrin and metalloprotease with a thrombospondin type 1 repeats-13, is a metalloprotease that cleaves VWF, reducing the size of VWF multimers and diminishing their prothrombotic features.[31] In STEMI patients, VWF levels are increased,[32,33] but it is not known whether this is related to infarct size and occurrence of no reflow and IMH. In parallel with the increase in VWF, ADAMTS13 decreases in STEMI patients.[32,33]

Recently, it was shown that ADAMTS13 knockout mice developed larger myocardial infarctions after coronary occlusion and showed decreased left ventricular function when compared with wild-type mice. Also, treatment with recombinant ADAMTS13 (rADAMTS13) reduced infarct size in wild-type mice.[34-36] However, the potential beneficial effects of rADAMTS13 on infarct size and infarct characteristics have never been tested in a large animal model of myocardial ischaemia-reperfusion. In the present study, the relationship between ADAMTS13 and VWF levels and CMR-derived infarct size as well as occurrence of IMH was determined prospectively in STEMI patients. Also, in a porcine model of myocardial ischaemia-reperfusion, closely resembling the clinical scenario of acute myocardial infarction (AMI) treated with primary PCI, intracoronary infusion of rADAMTS13 was tested for its effects on infarct size, formation of microthrombi, and IMH.

Regulation of Adamts13 Function

Cofactor – dependant regulation of coagulation enzymes have been well recognised. This increases the rate of an enzymatic reaction by several orders of magnitude [5]. Unlike other clotting factors that are being synthesised as inactive zymogens, ADAMTS13 is secreted as a constitutively active protease [4]. There has been no inhibitor identified till date. Plasma α2-macroglobulin inhibits many other matrix metalloprotease including ADAMTS-5,5,7 and 12[6]. But this does not seems to bind and affect ADAMTS13 activity towards VWF.

Therefore ADAMTS13 function must be regulated at its substrate level[7].Arterial shear stress can be simulated invitro using a cone plate viscometer, a bench-top-mini-vortex, and

micro fluidic system which generates the laminar flow [11]. Under mechanically induced shear stress, the proteolytic cleavage of multimeric VWF by recombinant ADAMTS13 increases as a function of increasing shear rate, incubation time and concentrations of ADAMTS13 enzyme[10]. This mechanical force-induced cleavage of an A1A2A3 tri-domain molecule or the A2 domain of VWF has already been demonstrated. These suggest that fluid shear stress place a major role in regulating the proteolytic cleavage of soluble VWF by ADAMTS13[12].

Structure-function analysis demonstrates that B-domain deleted FVIII variant (FVIII-SQ) exhibits a similar rate enhancing effect on proteolysis of VWF by ADAMTS13 as does full-length FVIII [15]. However FVIII variant lacking the acidic region which contains a major VWF binding site has no effect under the same conditions. There is an interesting fact that a light chain of FVIII (FVIII-LC), despite a 10-fold reduction in its binding affinity to VWF, is sufficient for accelerating the cleavage of VWF to a similar extent as are wild-type FVIII and FVIII-SQ[11], suggesting that binding of FVIII to VWF through its light chain mediates this cofactor activity.These biochemical findings are further corroborated with those obtained in vivo in a murine model. The hydro dynamic injection is a commonly used method to instantly transfect hepatocytes with plasmid of interest.

This manoeuvre also activates the endothelial cells which trigger the release of UL-VWF into plasma in mice. When this is injected with PBS alone, plasma ratios of high to low molecular weight VWF multimers in *fVIII*mice are higher *than* those in the *fVIII*mice reconstituted with a plasmid encoding FVIII-SQ or FVIII-LC[9], which suggest that the expression of a functional VWF-binding FVIII variant eliminates the accumulation of UL-VWF multimers under (patho)physiological conditions.

Ristocetin,which is an antibiotic that binds the A1 domain of VWF close to the site that GP1bα binds, also enhances cleavage of multimeric VWF by ADAMTS13[7,8]. These results suggest that the interaction between platelet GP1bα or (ristocetin) and the A1 domain plays a role where it affects the accessibility of the A2 domainn by ADAMTS13. There is an interesting fact thatristocetin alleviates the requirement of FVIII to enhance the cleavage of VWF by ADAMTS13 [9], whereas binding of platelet GP1bα to VWF enhances the effect of FVIII or vice versa as previously demonstrated.

Thus in the presence of physiological concentrations of platelets (150x103/µl), the C50 shifts to the left (from 5nM to 0.5nM)[7]. These results suggest that FVIII and platelet GO1b have

synergistic effects which enhances VWF proteolysis by ADAMTS13 under fluid shear stress. It has been postulated that the binding of FVIII to the D'D3 domain of VWF may result in large-scale conformational changes of the VWF multimers, which may include pulling away the D'D3 domain from its neighbouring A1 or A2 domain under shear stress.

Similarly, binding of platelets or soluble GP1bα to the VWF-A1 domain will expose the A2 domain for cleavage. Two or more platelets bound on each side of the scissile bond may dramatically increase the peak tensile force which is exerted on the central A2 domain[11], that enhances A2 domain unfolding and proteolysis by ADAMTS13, which are demonstrated by single molecule experiments[5,9,12].

Mechanism of Anti-Adamts13 Auto Anti Body Inhibition

Idiopathic TTP in adults is caused by a severe deficiency of plasma ADAMTS13 activity which is due to the immunoglobulin(IgG) type anti bodies[9]. The inhibitory anti bodies are detected in about 44-100% of acquired Idiopathic TTP patients where there is a severe deficiency of plasma ADAMTS13 activity[13]. Considering the sensitive assays such as enzyme-linked immunosorbent assay (ELISA) or flow cytometry-based technology, anti-ADAMTS13 IgGs can be deducted in all TTP patients who have severe deficiency of plasma ADAMTS13 activity.

The factors such as antibody mapping and profiling reveal that anti-ADAMTS13 IgG1 and IgG4 predominate in the plasma of acquired TTP patients. Also nearly all anti-ADAMTS13 IgGs bind the sys-rich and spacer domains particularly targeting the spacer domain [15]. Other ADAMTS13 domains including the propeptide, metalloprotease domain, disintegrin domain, first TSP1 repeat, more distil TSP1 repeats and CUB are less reactive when compared to the auto antibodies. Now a majority of TTP patients (approximately 90%) loose reactivity towards ADAMTS13 which follow the substitution of residues Arg568, Phe592, Arg660, Tyr661 and Tyr665 in exosite 3 of the spacer domain[14].

These residues has a major role in substrate recognition and proteolysis of VWF under certain conditions. Thus it is conceivable for the action of binding of anti-ADAMTS13 autoantibodies to this region because it place a role where it blocks the substrate binding and its proteolytic function[12].

Myocardial Infarction and Adamts-13 in Myocardial Infarction About 35% of the total population is being affected by myocardial infarction. This disease is most common. About 146000 people in the UK have an MI every year. It occursinpeople aged over 50 and this disease becomes more common with increase in age. Sometimes younger people are also affected. MI is three times more common in young men than young women. However after the menopause the female hormones present will no longer protect the heart and thus the risk is the same for both men and women.

MI may occur in people with diseases such as angina. It can also happen out of the blue in people with no previous symptoms of the heart disease. This is because atheroma often develops without leaving any symptoms at the first. Certain risk factors increase the risk of more atheroma forming. This can lead to ACS / MI.

Briefly, risk factors that can be modified and may help to prevent MI include:

- Smoking. If you smoke, you should make every effort to stop.
- High blood pressure. If your blood pressure is high it can be treated.
- If you are overweight, losing some weight is advised. Losing weight will reduce the amount of workload on your heart and also help to lower your blood pressure.
- A high cholesterol. This should usually be treated if it is high.
- Inactivity. You should aim to do some moderate physical activity on most days of the week for at least 30 minutes - for example, brisk walking, swimming, cycling, dancing, gardening, etc.
- Diet. You should aim to eat a healthy diet.
- Diabetes. People with diabetes have a higher risk of having ACS. This risk can be reduced by ensuring your blood pressure, cholesterol levels and glucose levels are well controlled.
- Family history. Your risk is increased if there is a family history of heart disease or a stroke that occurred in your father or brother aged below 55, or in your mother or sister aged below 65.
- Ethnic group. Certain ethnic groups - for example, British Asians - have a higher risk of developing cardiovascular disease.[2,9].

Treatment for Myocardial Infarction

Aspirin and Other Antiplatelet Medicines

As soon as possible after MI is suspected you will be given a dose of aspirin. Aspirin reduces the stickiness of platelets. Platelets are tiny particles in the blood that trigger the blood to clot. It is the platelets that become stuck on to a patch of atheroma inside an artery that go on to form the blood clot which leads to other complications such as thrombosis, etc[6]. Other antiplatelet medicines called clopidogrel or ticagrelor may be given. They work in a different way to aspirin and help reduce platelet stickiness. [4].

Injections of Heparin or Similar Medicine: These are usually given for a few days to help prevent further blood clots from forming.

Pain Relief:A strong painkiller such as morphine is given by injection into a vein to ease the pain.

Treatment to Restore Blood Flow in the Blocked Coronary Artery:

A coronary artery bypass graft (CABG) is a surgical procedure used to treat coronary heart disease. [40] The part of the heart muscle starved of blood does not die immediately. If blood flow is restored within a few hours, much of the heart muscle that would have been damaged and die will survive. This is why MI is a medical emergency, and treatment is given urgently. The quicker the blood flow is restored, the better the outlook.[5,1]. Anticoagulant drugs are commonly prescribed to patients with atrial fibrillation, pulmonary embolism, deep vein thrombosis, venous thromboembolism, congestive heart failure, stroke, myocardial infarction, genetic or acquired hypercoagulability, prosthetic heart valves and cardiac stents placement. [39]

There are two treatments that can restore blood flow back through the blocked artery:

- Emergency angioplasty. Ideally this is the best treatment if it is available and can be done within a few hours of symptoms starting. In this procedure a tiny wire with a balloon at the end is put into a large artery in the groin or arm. It is then passed up to the heart and into the blocked section of a coronary artery, using special X-ray guidance. The balloon is blown up inside the blocked part of the artery to open it wide again. A

stent may be left in the widened section of the artery. A stent is like a wire mesh tube which gives support to the artery and helps to keep the artery widened.[3].

- An injection of a clot-busting medicine is an alternative to emergency angioplasty. It can be given easily and quickly in most situations A beta-blocker medicine. Beta-blocker medicines block the action of certain hormones such as adrenaline (epinephrine). These hormones increase the rate and force of the heartbeat. Beta-blocker medicines have some protective effect on the heart muscle and they also help to prevent abnormal heart rhythms from developing. Beta-blocker medicines will also help to prevent having another MI.[8].

Insulin: Some people have a raised blood sugar level when they have an MI, even if they do not have diabetes. If this occurs, then your blood sugar levels may need to be controlled with insulin. If you have diabetes then it is also likely that you will need to be treated with insulin to control your blood glucose levels when you are in hospital.[13].

Oxygen: Oxygen is given which works to reduce the risk of damage to your heart muscle.

Conclusion

Cardiovascular disease is currently the major source of death in the developing countries,especially in India [37]. Employment of the serum cardiac markers rather than non-invasive or invasive procedures in the right time for accurate diagnosis of acute myocardial infarction (AMI) is a more important to restore the patient. [38]This aims in the improvement of nature and re-engineering ADAMTS13. We have demonstrated that the spacer domain particularly the exosite 3 which is the major target of anti-ADAMTS13 autoantibodies in patients with acquired TTP [2]. Thus the autoantibody which binds to this region is expected to block the substrate binding and inhibit its proteolytic activity of ADAMTS13. Replacement of residues in exosite 3 with alanine is expected to completely abolish anti-ADAMTS13 IgG binding but this also significantly impairs the proteolytic activity of ADAMTS13, which render this mutants which are useless for therapy [5].

There is an interesting fact that these variants were more resistant than WT and M1-M3 (with one to three residues mutated) to inhibition by anti-ADAMTS13 autoantibodies from acquired TTP patients. Thus these findings indicate that it is possible to re-engineer ADAMTS13 protease which improves its specific activity in the presence of autoantibodies

which offers therapeutic benefits to acquired TTP patients. Tremendous progress has been made in the past decade towards our understandings of the bio-synthesis, the structure-function relationship and co-factor – dependant regulation of ADAMTS13 function. These advances provides invaluable information which concerns the mechanisms of TTP and other atherothrombotic disorders as well as its inflammatory diseases. Hence novel diagnostic tools and therapeutics may be developed for managing these potentially fatal diseases[7].

Abstract

A circulating protein produced in adipocytes, called Acrp30 or adiponectin has insulin – mimetic and sensitizing actions in skeletal muscle and suppression of glucose production in liver. Adiponectin circulates as hexameric, oligomeric, to a lesser extent, trimetric forms. Adiponectin has attracted so many researchers because of its anti diabetic and anti atherogenic effects, which can be a therapeutic tool for diabetes and metabolic syndrome. Concentration of totaladiponectin in the blood is about 3-30µg/ml. High level of adiponectin reduce risk of coronary heart disease and myocardial infarction in healthy man. Human adiponectin consists of 244 amino acid residues and has a distinct domain structure. This review describes the pathophysiological role of adiponectin and its role in diseases.

Key Words: *Artherosclerosis,Hyperglycaemia,Hyperinsulinaemia,HMW(high molecular weight)*

Introduction

Adiponectin is an insulin-sharpening hormone with against diabetic, calming and hostile to atherogenic properties [1]. It is presently realized that fat tissue is a dynamic endocrine organ, emitting various organically dynamic proteins, otherwise called adipokines. Adiponectin is a protein formed and discharged solely by adiposities. Adipocytes are in charge of the formation of adiponectin, leptin, angiotensinogen and retinol-restricting protein. Some adipokines, including monocyte chemoattractant protein-1 and apelin, are created by the two parts [2].Adiponectin, likewise named Acrp30AdipoQapM1 or GBP28 was initially recognized autonomously by 4 bunches utilizing diverse methodologies. A littler type of adiponectin incorporates the globular space separates proteolytically from full-length adiponectin and exists in plasma, in spite of the fact that in little sums .Adiponectin associates adversely with serum triacylglycerol (triglyceride) and emphatically with serum HDL cholesterol in non-diabetic ladies or youthful solid man [3]. Plasma adiponectin level in human range from 0.5 to 30g/ml, which is around 1000-crease higher than the centralizations of most different hormones, for example, leptin, insulin and so on. In fact, adiponectin represents 0.01 % of aggregate human plasma proteins and is the most plentiful fat tissue protein [4]. The nearness of corpulence to a vast degree expands the danger of related comorbidities, for example, insulin obstruction, diabetes, dyslipidemia, hypertension and others. The blend of the previously mentioned pathologies is currently by and large alluded to as the metabolic disorder or disorder X [5]. Moreover, adiponectin has a potential part in the focal direction of vitality admission and consumption.

Structure

The literal structure of the HMWform of adiponectin is not yet known. Most likely several combined hexamers and/or trimers constitute high-molecular weight form of adiponectin. It is commonly supposed that disulfide bonds on top of some bonds with involvement of modified amino acid residues in collagen domain of adiponectin, take part in holding subunits of HMW form of adiponectin together .It is also believed that those oligomeric forms exist in the bloodstream as separate moieties and do not renovate into each other [6]. It has been revealed recently, that adiponectin oligomers are capable of binding Ca2+ ions which are thought to participate in maintenance of conformational steadiness of adiponectin. In plasma, its structural resemblance to complement factor C1q and the consistent finding of decreased

levels in obesity [7]. Full-length adiponectin motivated AMP-activated protein kinase (AMPK) phosphorylation and activation in the liver, while globular adiponectin do so in both skeletal muscle and the liver .

Unexpectedly, genes expressed in subcutaneous and visceral adipose tissue, 20% and 30% respectively, were bioactive secretory proteins, i.e. adipocytokines such as leptin and TNF-*α*. More surprisingly, 40%of the genes expressed in adipose tissue were novel and the most abundant among them, termed adiponectin, was novel as well.Adiponectin is the most abundant adipocytokine. Unlike leptin and other adipose tissue-derived hormones which circulateatpicograms or nanograms per milliliter, adiponectin circulates at very high levels (micrograms per milliliter). It circulates as several multimeric species, including a high molecular- weight (HMW) form thought to be the most clinically relevant.

Adiponectincontains 244 amino acids, a signal peptide, a collagen like domain at its N-terminus and a globular domain at its C-terminus, which shares sequence similarity with collagens X and VIII as well as complement factor C1q.In spite of the absence of primary sequence similarity, the crystal structure of the C-terminal globular domain resembles that of TNF-*α* [8]. Structurally, adiponectin belongs to the complement 1q family. Adiponectin monomer consists of an N-terminal collagenous domain and a C-terminal globular domain [9] that generates low-molecular-weight dimers or trimers, medium (hexamers) and high-molecular-weight complexes (HMW, dodecamers and 18 mers) in mammalian plasma[10]. The three multimeric forms are found in the circulation, associated with several serum proteins [11]. The globular fragment was also detected in the trimeric form in human and mouse plasmas and was shown to be generated by proteolytic cleavage [12].Collagen-like parts of three adiponectin molecules can work together forming triple coiled coil structure much alike to that in collagen.

Adiponectin Blood Test

Adiponectin is a hormone discharged by fat cells. It manages tissue aggravation and responsiveness to insulin is made by beta cells of the pancreas. It is discharged in blood after an ascent in blood glucose level, (for example, after a substantial feast) to help bring down it to typical levels. Insulin does this by fortifying cells to 'take in' glucose (and other nutrients).The most regular reason for lifted glucose is diabetes mellitus, or just "diabetes". There are 3 kinds of diabetes mellitus, all of which influence insulin work: Type 1 or insulin-

subordinate diabetes comes about because of the immune system obliteration of beta cells of the pancreas. Sort 2 or insulin-autonomous diabetes comes about because of the desensitization of cells to the impacts of insulin.Gestational diabetes may happen amid pregnancy and result in exorbitantly substantial children that display low glucose levels. Insulin affectability alludes to the degree to which cells react to insulin. Diabetes, heftiness, and other metabolic issue are related with low insulin sensitivity [13].Adiponectin raises insulin affectability. It builds the breakdown of unsaturated fats and abatements the generation of glucose by the liver. People with weight, type II diabetes, and other metabolic issue frequently have low adiponectin levels in blood. The Adiponectin Blood Test decides the levels of adiponectin in blood. It is utilized to analyze metabolic clutters, for example, type II diabetes.

Clinical Indications for Playing Out the Adiponectin Blood Test

Following are the clinical signs for playing out the Adiponectin Blood Test:

1.Frequent pee

2.Increased thirst

3.Fatigue

4.Blurry vision

5.Rapid weight reduction

6.Tingling and desensitizing in the furthest points

7.Obesity

8.History of cardiovascular illness

Example Accumulation ofAdiponectin Blood Test

Following is the example accumulation process for Adiponectin blood test

Test required- Blood

Procedure of acquiring blood test in grown-ups:

•A band is wrapped around the arm, 3-4 crawls over the accumulation site (shallow vein that exists in the elbow pit)

•The site is cleaned with 70% liquor in an outward winding, far from the zone of needle addition

•The needle top is evacuated and is held in accordance with the vein, pulling the skin tight

•With a little and snappy push, the vein is infiltrated utilizing the needle

•The required measure of blood test is gathered by pulling the plunger of the syringe out gradually

•The wrap band is evacuated, bandage is put on the accumulation site, and the needle is expelled

•The blood is quickly moved into the blood compartment, which has the proper additive/cluster activator/hostile to coagulant

•The syringe and the needle are arranged into the fitting "sharp compartment" for protected and sterile transfer

Arrangement required: No uncommon readiness is required before the test [14].

Adiponectinin Health and Disease

Diminished serum adiponectin fixation show insulin opposition and sort 2 diabetes. Additionally, hypoadiponectinemia was uncovered to be related with coronary conduit sickness . In people, adiponectin is an insulin-sharpening, vascular defensive, calming protein related with a more great lipoprotein subclass profile. Low coursing levels, especially of the HMW segment [15] are likewise a solid hazard marker for the advancement of the metabolic disorder and sort 2 diabetes . The fat cells in adipocytes may discharge cytokines as adiponectin and resistin. Adiponectin stays ordinary barring in the event of diabetes and weight it lessen [16].

A forthcoming investigation of patients with renal disappointment exhibited that patients who qualified new cardiovascular occasions had bring down plasma adiponectin levels. The fat tissue be an outsized resorvior of organically dynamic middle people for example Tumor putrefaction factor - α, and different adipokines, for example, leptin, resistin and adiponectin in provocative process [17]. Irritation describes atherosclerosis and large subjects, and people at high danger of atherosclerosis have elevated amounts of intense stage reactants, for example, CRP (C-responsive protein), an effective marker for foundational aggravation and an autonomous hazard factor for CAD. Myocardial hypertrophy and diastolic brokenness can go with diabetes and heftiness related conditions. Unsaturated fat oxidation was hoisted by the proteolytic section of adiponectin, most presumably because of expanded articulation of qualities engaged with beta oxidation and vitality dispersal in muscle.

The consumption of lipid stores from adipocytes amid interminable calorie confinement additionally prompts raised adiponectin levels in blood. Clinical examination utilizing CT

(PC tomography) checking demonstrates that stoutness with instinctive fat gathering (instinctive fat weight) relates intimately with diabetes mellitus, hyperlipidaemia, hypertension and atherosclerosis as of late, adiponectin was presented to be available in the cerebrospinal liquid (CSF) of rodents and people and to enter the CSF from the flow .

AdiponectinRole in Diabetes

Adiponectin levels appear to be decreased before the advancement of sort 2 diabetes, and organization of adiponectin has been joined by bring down plasma glucose levels and in addition expanded insulin affectability. Moreover, lessened articulation of adiponectin has been related with some level of insulin obstruction for hypoadiponectinaemia in connection to insulin opposition. The essential systems by which adiponectin improve insulin affectability seems, by all accounts, to be through expanded unsaturated fat oxidation and hindrance of hepatic glucose generation [18] .Adiponectin levels are expanded by thiazoledinedione treatment, and this impact may be critical for the upgraded insulin affectability prompted by thiazolidinediones. Interestingly, adiponectin levels are lessened by star incendiary cytokines particularly tumor corruption factor-alpha. In rundown, adiponectin notwithstanding conceivable mitigating and against atherogenic impacts seems, by all accounts, to be an insulin enhancer, with potential as another pharmacologic treatment methodology of the metabolic disorder and sort 2 diabetes.

It has been demonstrated that CSF contains bring down levels of adiponectin contrasted and serum in rodents [19], and this level builds resulting to intravenous infusion of adiponectin affirming its capacity to enter the cerebrum from the flow. Globular adiponectin shielded mice from diabetes and apolipoprotein E-inadequate mice from atherosclerosis [20] showing that globular adiponectin is likewise proficient as the full-length. Adiponectin has antidiabetic properties because of insulin-mimetic and insulin-sharpening activities, while mitigating and hostile to atherosclerotic impacts have likewise been continually detailed.

AdiponectinReceptors

Three adiponectin receptors, AdipoR1, AdipoR2 and T-cadherin, have been well-known. AdipoR1 is ubiquitous, but is most abundantly expressed in skeletal muscle is a receptor for hexameric and HMW adiponectin . Expression of AdipoR1 and AdipoR2 or suppression of AdipoR1 and AdipoR2 expression supports our conclusion that AdipoR1 and AdipoR2 serve as receptors for globular and full-length adiponectin and mediate increased AMPK, PPARα

ligand activities, fattyacid oxidation, and glucose uptake by adiponectin. A classical model of accelerated atherosclerosis apolipoproteinE(ApoE)-deficient transgenic mice, or the double transgenic ApoE/leptin-deficient mice led to amelioration of atherosclerosis in both models. This effect was accompanied by reduced expression of class A scavenger receptor and TNF [21].

In addition to sex, nutritional status and body weight, other factors affecting plasma adiponectin levels include menopausal status, and medications such as b-blockers and angiotensin II receptor blockers .However, the age of the study subjects was greater than 65 years, and therefore, all the female participants were menopausal [22]. Furthermore, the use of b-blockers and angiotensin II receptor blockers was not different between the three subgroups. Further analyses revealed that adiponectin depolarized PA neurons expressing both receptors Adip-R1 and Adip-R2, whereas AP neurons expressing only one receptor were insensitive indicating different roles of adiponectin and differentpathways of its receptors in controlling excitability of AP neurons.On the other hand, macrophage polarization phenotype regulates the expression of adiponectin receptors (AdipoRs) in ways that classical activation (M1) of macrophages suppresses [23] the expression of AdipoRs, and alternative activation (M2) preserves it .

AdiponectinSignalling and Function in Insulin and Target Tissue

APPL1 Protein

Adiponectin inspires various downstream flagging occasions. Be that as it may, no inborn protein kinase movement or phosphorylation because of adiponectin has ever been recognized in either AdipoR1 or AdipoR2. Moreover, substitution of the tyrosine deposits inside the intracellular N-end by site-coordinated mutagenesis has no effect on adiponectin flagging. Along these lines, the adiponectin receptors are likely transmembrane receptors that experience conformational change and couple the intracellular space with other flagging particles upon extracellular adiponectin official. Utilizing yeast two-crossover innovation recognized that APPL1 as the intracellular restricting accomplice of AdipoR1 and AdipoR2. The human Appl1 quality is situated in the 3p14.3-21.1 locale and encodes a 709-amino corrosive protein of 78 kDa.

Human hereditary examinations recommend that SNPs and point changes in the Appl1 coding district correspond with muscle versus fat conveyance and a high commonness of

diabetes.APPL1 is profoundly hydrophilic with no potential transmembrane locale and comprised of numerous auxiliary and useful spaces including BAR, PH, PTB, and looped curl (CC) .APPL1 straightforwardly ties to the intracellular areas of AdipoR1 and AdipoR2 by means of its C-terminal PTB and CC spaces, subsequently interceding the activities of adiponectin in the control of vitality digestion and insulin affectability .In refined skeletal muscle cells, concealment of APPL1 articulation decreased adiponectin-actuated glucose take-up and GLUT4 translocation.

On the other hand, overexpression of APPL1 upgraded the stimulatory activities of adiponectin in glucose digestion in muscle.Rab5, a GTPase downstream of APPL1, assumes an imperative part in APPL1-intervened adiponectin flagging .The significant activity of adiponectin on lipid digestion is to advance unsaturated fat oxidation, a procedure in which AMPK and acetyl CoA carboxylase (ACC) assume a basic part. Upon adiponectin incitement, APPL1 ties to protein phosphatase 2A (PP2A) and protein kinase, along these lines actuating PP2A and inactivating PKC by means of dephosphorylation. The inactivation of PKC brings about the dephosphorylation on liver kinase B1 (LKB1), enabling LKB1 to translocate from core to cytoplasm and initiate AMPK .notwithstanding the AMPK pathway,

APPL1 additionally intercedes adiponectin-prompted actuation of the p38 MAPK pathway and researched its effect on the mitigating activities of adiponectin . APPL1 fastened p38 MAPK together with its upstream initiating kinases including changing development factor-β actuated kinase 1 (TAK1) and mitogen-enacted protein kinase 3 (MKK3), accordingly assisting the phosphorylation of key compounds of this pathway [24].Interestingly, the activity of APPL1 on p38 MAPK pathway is particular to adiponectin, while its effect on TNF-α-incited p38 MAPK enactment is restricted . APPL1 in interceding the activities of adiponectin. Entire body knockout of APPL1 hinders adiponectin flagging and results in insulin opposition in significant insulin target tissue.

APPL2 Protein

APPL2 is an isoform of APPL1 and offers homology in amino corrosive succession with APPL1 protein .Similar to APPL1, APPL2 has a N-terminal BAR area, focal PH space, and C-terminal PTB space. APPL2 intervenes FSH flag transduction by authoritative to APPL1 through their individual BAR areas, which brings about the development of the FSH receptor– APPL1– AKT2 complex. Quite, APPL2 does not straightforwardly connect with

AKT2 [25]. APPL2 contrarily regulates adiponectin motioning in skeletal muscle cells. APPL2 specifically ties to AdipoR1 or AdipoR2 by means of its BAR space, in this way keeping the connection of APPL1 with AdipoRs. Therefore, APPL2 pieces adiponectin motioning through AdipoR1 and AdipoR2 by aggressive hindrance of APPL1. Moreover, APPL2 heterodimerizes with APPL1, in this way diminishing the authoritative of APPL1 to AdipoRs and debilitating the activities of adiponectin. Strangely, adiponectin balances the separation of the APPL1/APPL2 heterodimers, which can likewise be activated by insulin and metformin .Because APPL1 and APPL2 apply inverse activities in interceding adiponectin flagging, proposed the 'Yin and Yang' modulatory idea [26].

The Yin and Yang modulatory idea including APPL1/APPL2 offers a point by point atomic instrument by which adiponectin controls lipid and starch digestion. Predictable with the Yin-Yang hypothesis, with muscle-particular APPL2 removal or overexpression indicate individual upgraded or weakened insulin affectability, insulin-animated GLUT4 translocation, and glucose take-up in skeletal muscle .The restricting parts of APPL1 and APPL2 were additionally seen in the direction of the PI3K/AKT/NF-κB pathway in macrophages .

The AMPK Pathway

AMPK, a protein kinase managed by AMP, is a broadly perceived cell sensor for metabolic state. In skeletal muscle, both full-length adiponectin and the globular space have been appeared to trigger AMPK phosphorylation, prompting AMPK actuation .APPL1 assumes a key part in adiponectin-interceded AMPK phosphorylation .In essential culture of skeletal muscle detached from corpulent people or patients with type 2 diabetes, AMPK phosphorylation because of adiponectin is incredibly decreased, exhibiting that disabled flagging downstream of the adiponectin receptor may weaken the activities of adiponectin or cause adiponectin obstruction .Adiponectin has additionally been appeared to initiate AMPK phosphorylation in the liver[27]. Notably, constrained part of the AMPK pathway in the control of gluconeogenesis .At introduce, in any case, no different components, i.e. non-AMPK pathways, have been appeared to intervene the impacts of adiponectin on gluconeogenesis in the liver.

The PPAR pathway

Another key translation factor in metabolic direction is PPAR-α. In skeletal muscle, adiponectin definitely builds the articulation and action of PPAR-α, which thus upregulates acetyl CoA oxidase (ACO) and uncoupling proteins (UCPs), in this manner advancing unsaturated fat oxidation and vitality consumption .In the liver, adiponectinupregulates a few PPAR-α target qualities including CD36, which tweaks hepatic unsaturated fat take-up and digestion and ACO, which controls unsaturated fat oxidation .what's more, adiponectin has been appeared to expand hepatic glucose take-up through PPAR-α, in this manner enhancing hepatic insulin affectability [28].

Thiazolidinedione (TZD) class of PPAR-γ ligands upregulatesadiponectin articulation in adipocytes .The impact of TZDs on enhancing glucose resistance is debilitated in adiponectin-inadequate mice, showing that adiponectin intercedes, in any event to a limited extent, the insulin-sharpening activities of TZDs .The declaration of PPAR-γ is notably expanded in 3T3-L1 cells overexpressingadiponectin, which is related with improved adipocyte separation ,demonstrating that adiponectin advances the PPAR-γ pathway, in this way actuating a positive criticism circle that increments adiponectin articulation and adipocyte separation.

Other Adiponectin Flagging Pathways

Notwithstanding the pathways examined above, adiponectin has been appeared to instigate calcium discharge from sarcoplasmic reticulum in myocytes or advance calcium inundation, in this way actuating Ca2+/calmodulin-subordinate protein kinase (CaMKK-β) and AMPK, which brings about initiation of SIRT1 and PPAR-α and increment of mitochondria biogenesis .what's more, ceramide-interceded pathways likewise have been embroiled in intervening the activities of adiponectin revealed that both AdipoR1 and AdipoR2 are related with ceramidase exercises, which, upon adiponectin official, powerfully improves ceramides transformation to S1P [29]. A procedure that is autonomous of AMPK. The p38 MAPK pathway likewise assumes a part in adiponectinflagging .

Adipor1 Concealment Compounds Alzheimer's Infection like Pathologies

Pathogenic systems hidden the psychological weakness of spatial learning and memory and neurodegeneration. ADPN-AdipoR1 flagging pathway have a noteworthy part of insulin-sharpening impact through actuating protein kinase B (PKB or AKT) .AdipoR1 inadequacy

influences insulin-responsive phenotype, insulin in HT22 cells by dosage subordinate way. Curiously, AKD amass displayed lessened AKT phosphorylation contrasted and Scraggregate . Besides, AD-like neuropathologies, for example, proteinopathies and neuroinflammation .Preferentially, unusual protein collection, for example, Aβ creation and hyperphosphorylation. Aβ generation was significantly expanded in AKD .

Next, we explored whether glycogen synthase kinase 3β (GSK3β) shape is dynamic or not because of its part for tau hyperphosphorylation. Despite the fact that articulation level of GSK3β are exceedingly up managed in the two areas of AKD mice, phosphorylation of GSK3β at serine 9, thinking about an inhibitory shape, was diminished in the cortex of AKD mice with the exception of hippocampus . Successively, tau protein phosphorylation at serine 396/404 (combined helical fibers or PHF-1) in was profoundly controlled in the two districts of AKD mice, add up to tau (Tau5) level additionally expanded in AKD .neuroinflammatory phenotypes utilizing microglial marker and expert provocative cytokines. Ionized calcium-restricting connector particle 1 (Iba-1) and tumor-corruption factor alpha (TNF-α) level were up-controlled in AKD .

AdipoR1 knockdown in microglial cell line BV-2 showed M1 polarization, professional provocative phenotype, under the basal condition [29]. In synopsis, AdipoR1 knockdown have demonstrated neurodegeneration-interceded memory brokenness and in addition worldwide AD-like pathologies including insulin flagging brokenness, proteinopathies and neuroinflammation.

Adipor-Autonomous Activities of Adiponectin

Adiponectin receptor-intervened activities in different adiponectin target tissues, uncover that adiponectin applies some receptor-free exercises. adiponectin-responsive pre-autonomic (PA) neurons in the hypothalamus don't express AdipoR1 or AdipoR2 . Adiponectin could act in a roundabout way on those AdipoR− PA neurons through endocannabinoidsorneuromodulatory peptides discharged from the AdipoR+neurons because of adiponectin [30]. Adiponectin encourages the take-up of early apoptotic cells by macrophages and adjusts incendiary reactions through a receptor-subordinate pathway that includes calreticulin. RNAi-interceded thumping down of AdipoR1, AdipoR2, and T-cadherin does not influence adiponectin-animated expulsion of apoptotic bodies by macrophages by means of

calreticulindemonstrating that the procedure is free of the known AdipoRs engaged with the established metabolic direction.

Theoretically, receptor-subordinate intracellular flagging for the most part requires low circling ligand focuses, while receptor-free impacts are likely interceded by significantly higher ligand fixations. The physiological groupings of plasma adiponectin is ∼1000-crease higher than that of insulin and further investigations are expected to decide if adiponectin works through both receptor-subordinate mechanisms [31].

Future Difficulties and New Skylines

While adiponectin itself is certainly not an appropriate contender for insulin-sharpening drugs, segments of the adiponectin flagging pathway are promising druggable targets. little particle activator of the adiponectin receptor, AdipoRon, enhances glucose resilience and enhances insulin opposition encouraged a high-fat eating routine. Thus, little atoms that improve adiponectin flagging might be suitable alternatives for the treatment of stoutness connected metabolic maladies including type 2 diabetes. Nonetheless, the present test is that the Kd for little atoms, for example, AdipoRon authoritative to the AdipoR1 or AdipoR2 is considerably higher than that of the full-length or globular space of adiponectin, showing that high-partiality little particle AdipoR activators stay to be recognized [32].

Certain metabolic maladies, for example, type 1 diabetes and IR counter acting agent initiated type B insulin obstruction show high plasma groupings of adiponectin. Regardless of whether this wonder is a consequence of adiponectin obstruction, or compensatory increment to neutralize the inadequate or weakened insulin flagging, is yet to be determined [33]. Exhaustive comprehension of adiponectin and its downstream flagging pathways will give a manual for the advancement of novel medications in the treatment of corpulence related metabolic maladies.

Conclusion

Adiponectin has wide range of physiological and metabolical effects. It also appears to be cardioprotective and involved in modulating the inflammatory response. Its role in systemic inflammation and critical illness is not well-defined .More research is required to establish its role in inflammatory in metabolism.

Abstract

The aim of this study is to review that over consumption of carbonated soft drinks is a common cause of oral diseases and to understand the oral problems caused by the consumption of carbonated soft drinks.The consumption of soft drinks has increased dramatically over past several decades.The greatest increase in soft drink consumption has occurred among children and adolescents.Dentists are becoming more concerned about over consumption of soft drinks which results in dental disease.High soft drink consumption leads to excessive caloricintake,which causes childhood obesity,a growing problem among children.All soft drinks are acidic which corrodes the teeth by eroding its enamel.The high amount of sugar consumed through soft drinks lead to the development of bacteria that attack the teeth thus aggravating dental problems.From various studies it has been found that carbonated drinks are more aggressive towards dental erosion.hence this articlereviews the adverse effects of carbonated drinks and provides knowledge to the patients about the consequences of soft drink consumption to minimise the risk.

Key Words:*Carbonated drinks,decades,acidic,dental erosion.*

Introduction

Soft drink consumption has become a highly visible with increase energy intake and body weight(1).The soft drinks are popular beverages(2).Recent research has shown that carbonated drinks can have serious effects on teeth in terms of erosion(3).A soft drink is a beverage that is carbonated and it does not contain alcohol.Refreshments like colas, shimmering water , ice tea, lemonade , squash, and organic product punch are among the most widely recognized sorts of sodas, while hot chocolate, hot tea, espresso, drain, tap water, and milkshakes don't fall into this characterisation (4).Carbonation occurs when carbon dioxide is dissolved in water or an aqueous solution(5).

Generally soft drinks are composed of filtered water,artificial additives and refined sugar.They usually lack nutritional value and add up calories and it makes you gain weight. Soft drinks containing inherent acids and sugars have both acidogenic and cariogenic potential. It has been found that dental erosion is considered as a clinical problem in the oral health of school children and young adults and acidic drinks are thought to be an important cause(6).Now days children started consuming soft drinks at a young age, and consumption increases through young adulthood(7).High consumption of soft drinks and other sugary drinks are associated with a number of health problems, including overweight and obesity, type 2 diabetes, osteoporosis and dental caries(8).

High soda pop consumption is linked with widespread demineralization of enamel and extensive caries in pits and fissures and in the interproximal areas(9).It has been found that males of 13 to 18 years old drank two or more cans of soft drinks a day, while females of 13- to 18-year-old drank two cans per day. Adolescents prefer the taste of soft drinks while younger children prefer the taste of still fruit-flavored drinks (10).Those with the strongest taste preference for soft drinks consume more than those with lesser taste preferences.Parental influences such as parental consumption and parenting style are also important factors(11).Causative components for tooth disintegration are isolated into extraneous and inborn classes. Inborn disintegration happens from automatic gastrointestinal unsettling influences, for example, gastroesophageal reflux ailment (GERD) and from intentional disgorging of gastric acids showed by anorexic as well as bulimic people(12).Outward tooth disintegration causes incorporate natural elements, medicaments, way of life, and eating regimen. In present day social orders the outward

factor is ending up more critical, because of the expanded utilization of corrosive beverages as soda pops, don drinks, organic product squeezes and natural product teas(13). Thus this article educates the patient about the adverse effects of carbonated soft drink consumption.

pH of Beverages

Table 1: pH of Beverages

Beverages	PH Value
1. Coca-cola	2.48
2. Sprite	3.27
3. 7up	3.19
4. Pepsi	3.3
5. Mountain dew	3.14

Most soda pops contain maybe a couple regular sustenance acidulants - phosphoric corrosive and citrus extract. Periodically, different acidulants, for example, malic corrosive or tartaric corrosive are additionally used(14).The pH shows how acidic something is. A customary mouth has a pH of 6.3 to 7, which is close unprejudiced with no mischief done to teeth.The pH of the refreshments won't change notwithstanding when the drinks are left revealed at room temperature(15).Many basic drinks have pHs adequately low to dissolve and diminish the lacquer surface(16).All soda pops are exceptionally acidic, yet dim colas, for example, Coke and Pepsi are considerably more acidic. Creature examines have demonstrated that phosphoric corrosive is exceptionally erosive at pH 2.5 however significantly less so at pH 3.3. Citrus, malic and tartaric acids are thought to be particularly erosive as a result of their acidic nature and the capacity to chelate calcium at higher pH.5 Citric corrosive was more erosive than malic corrosive when planned to exploratory beverages at high pH(17).

Effects of Acidic Beverages on Tooth

It is well known that disease loves acid, and particularly true of dental caries. Dental caries, by definition, is tooth demineralization caused by acidic byproducts of the bacterial fermentation of dietary sugars.These acidic, or low pH, beverages can contribute to the demineralization of dental hard tissues(18).The soft drinks are thought to cause damage to the teeth because of two properties – first, the low pH and acidity of some drinks can cause erosion on the enamel surfaces and secondly the fermentablecarbohydrate in drinks is metabolized by plaque micro-organisms to generateorganicacids in the dental plaque and saliva, resulting in demineralization and leading to dental caries(19).Acidic drinks have recognized as a powerful extrinsic factor of dental erosion (20).Studies have discovered that a high commonness of dental disintegration in youngsters and youthful grown-ups identifies with their soda pop utilization or other dietary component. Dental pits are related with carbonated beverage.This is vital in light of the fact that the measure of sugars that are expended is imperative in shaping caries, which is the point at which a hole influences just the veneer, the external defensive layer of a tooth. Individuals who drink at least three glasses of circulated air through beverages (vaporous beverages) every day have substantially higher odds of dental rot, fillings and teeth misfortune.Therefore, soft drinks contain acid and sugar that corrode and destroy the teeth in one shot(21).

Role of Carbonated Drink Consumption on Dental Erosion and Tooth Decay

Tooth deterioration, or tooth wear, is the loss of tooth structure.Basically, tooth disintegration alludes to the wearing endlessly of the critical step of your teeth, which is called polish.The ideal (neutral) pH of the mouth ranges from 6.5-7.5. A pH of 5.5 is considered to be the threshold level for the development of dental decay. Both soft drinks and sports drinks have been shown to have a pH between 2.5 and 3.5. The normal reason for dental disintegration in youngsters is probably going to be acidic refreshments, for example, carbonated games beverages and natural product juices. These have been accounted for to be related with serious loss of dental veneer, especially when expended amid periods when there is little spit in the mouth, for example, instantly after substantial donning exercises (22).Dental erosion seems to have much stronger relationship with soft

drinks. The erosive potential of drinks is mainly represented by their pH and the buffering capacity.More studies showed that dental erosion was associated with the drinking methods. Holding the drink longer in the mouth leads to a more pronounced pH drop(23). Drinking with an increasing flow rate and with decreasing outlet diameter could increase the erosion depth (24). The effect is also strengthened when acid temperature grows higher(25).Few studies have reported that Animal studies have shown that phosphoric acid is very erosive at pH 2.5 but much less so at pH 3.3. Citrus, malic and tartaric acids are thought to be particularly erosive in view of their acidic nature and the capacity to chelate calcium at higher pH.5. Citrus extract was more erosive than malic corrosive when defined to test drinks at high pH.This acid, plus the extra acid already present in the drink, demineralizes (weakens) your tooth enamel. The enamel is the strong, outer coating of the teeth that guards against tooth decay and protects the teeth lifelong.When the acid makes it weak, tooth decay (cavities) can begin. Refined sugars play a pivotal role in the caries (tooth decay) process. Regular (non-diet) soft drinks contain large amounts of sucrose or high fructose corn syrup that are considered to be highly cariogenic (high decay potential). A recent study in the U.S. showed a positive relationship between cumulative caries (tooth decay) scores and the frequency of mealtime and between-meal use of carbonated beverages. Daily between-meal consumption of soft drinks three or more times per day has been shown to increase the risk of dental decay by 179%. Research has shown that bedtime is the worst time to consume sugar-sweetened drinks.

Signs of Soft Drink Erosion

There would be a change in morphology and surface characteristics of the teeth .Smooth surface enamel may develop broad shiny concavities. The teeth may even have a glazed appearance(26).

Wide buccal concavities in mandibular premolars and molar.Concavities with an enamel cuff at the free gingival margin. Deep shiny concavities occlusally in premolars and molars.Restorations that ‘rise’ above the occlusal surface.Sealants that ‘rise’ above the occlusal surface.Thin maxillary central incisors.Increased incisal translucency in maxillary central incisors.Surface characteristics missing.Loss of surface detail in the

primary dentition(27).

Dental examination found that crescent-shaped lesions were present on the cervical region of the buccal and labial surfaces of the teeth of thepatients(28). The individual manner of drinking acidic soft drinks has been said to affect how long the teeth are in contact with the erosive challenge and therefore influence the pattern of destruction caused by them. The drinking method strongly affects tooth-surface pH and thereby the risk for dental erosion. Six different methods of drinking were tested in a randomized order by Johansson Holding; short-sipping; long-sipping; gulping; nipping; and sucking(29).

Other Health Risks Associated with Softdrinks

It likewise is critical for general dental practitioners to comprehend the foundational wellbeing results of over the top utilization of sodas. Expanded vitality consumption identified with sodas has been related with an expanded level of corpulence among American kids and young people(30).Another result of expanded soda pop utilization has been a decrease in the utilization of dairy items. This has brought about the dislodging of many required supplements for the two youngsters and teenagers and in addition for grown-up females(31).Consuming more phosphate than calcium can have a deleterious effect on bone health(32). The Nurses' Health Study, which followed the soundness of about 90,000 ladies more than two decades, found that ladies who drank more than two servings of sugary drink every day had a 40 percent higher danger of heart assaults or demise from coronary illness than ladies who infrequently drank sugary refreshments(33).

Results from Other Studies

Al-Majed found an on a very basic level higher inescapability of dental crumbling in young women (29.9%) than in young fellows (25.7%), which is in simultaneousness with the results of past examination of 12-year-old Cuban children by Künzel,However, Dugmore besides, Truin. have found an in a general sense higher regularity in young fellows than in young women, while Correr, Peres likewise, Ping Wang et al. found no complexity between sexual introductions. Nazriya,found that Carbonated drinks,

particularly coke has most astounding pH and buffering limit took after by Fanta and Sprite. An examination by priyadharshini et al indicated 78.5% of the young people among chennai populace are dependent on carbonated refreshments. An examination by MahumuthaAffshana propose that disintegration is as predominant in chennai teenagers. Conceivable reason may incorporate Sampling variety or territorial varieties. Another examination by shreds.s,2015 was discovered that 73% of understudies favored carbonated beverages. An in vitro consider by Grenby ,recommendedtitratable corrosive was a superior guide than pH to decide erosive properties of refreshments. Be that as it may, add up to sharpness or pH estimations of refreshments couldn't be utilized with dependability to foresee their capability to cause molar disintegration. An investigation Hassan et al looked at corrosive freedom of noncarbonated and carbonated soda pops in the mouth, there was no measurable contrast in the leeway between the beverages. It was reasoned that carbonation may not specifically in charge of the erosive capability of various refreshments. Levitch,further recommended that a blend of disintegration and scraped spot may work synergistically to advance improvement of non-carious cervical injuries. The clinical ramifications of this is toothbrushing promptly after ingestion of acidic substances or refreshments may accomplish more damage than great by quickening tooth structure misfortune. A few investigations have uncovered lessened salivary cushion limit in patients with disintegration when contrasted and controls while others affirm low salivary stream rates as the significant determinants in a few patients with disintegration.

Reducing Tooth Decay and Dental Erosion

Drink fluoridated water and use fluoride toothpaste.

Swish out your mouth with water to dilute the sugar and acid.

Use a straw to keep sugars and acids away from your teeth.

Never consume soft drinks or juice at bedtime. (The liquid pools in your mouth and coats your tongue and teeth.)(46).

Discard the top to anticipate progressing tasting.

Read the names sweetened beverages are high in sugar.

Get regular dental cleanings to remove plaque (bacteria) build-up on your teeth(47).

Edwards and co-workers recommended that drinking through a straw positioned toward

the back of the mouth may reduce the erosive potential of soft drinks(48).

Patient should avoid toothbrushing enamel which has been softened by exposure to black cola. This may cause additional material loss due to tooth brush abrasion(49) Kids ought to be urged to drink acidic beverages rapidly and utilize a straw with the goal that the fluid is pushed to the back of the mouth.Also, avoid buying re-sealable bottles and discourage sipping over a long period of time. The liquid fruits can be used as a natural alternative to synthetic beverages(50).

Conclusion

Excessive intake of soft drinks could cause complex dental consequences including dental erosion and caries.It is necessary to educate patients about the harmful effects of excessive soft drink consumption.fluoride can be used to decrease the potential ravages of soda pop.Programmes could bedeveloped and administered in schools, though there is also clearly a role for parents in helping to reduce carbonated drink consumptionindicated by the increased consumption at weekends.Conversely, the negative effects of carbonated drink consumption should be emphasized to younger generations.

Abstract:

Aim and objective: To evaluate use of albumin as a biochemical marker for detection of acute myocardial syndrome.

Background: Myocardial Ischemia occurs when there is a lack of blood perfusion of the myocytes, leading to deficiency of oxygen and nutrients, thus affecting their vital functions. The diagnosis of cardiac ischemia always remains as a challenge in emergency medicine. There is a need for early and sensitive markers of cardiac ischemia as current diagnostic tests fail to identify many chest pain patients and who are at a high risk for adverse cardiac events. A number of candidate biomarkers have been released for the detection of cardiac ischemia however, ischemia modified albumin(IMA) is proven to be the most efficient and has been released for usage in clinics. Changes in IMA concentration have shown to occur during coronary angioplasty-induced ischemia. Clinical studies indicate that IMA appears to offer on admission an early test which can be combined with electrocardiographic findings and cardiac troponin measurements for the early exclusion of acute coronary syndrome. The mechanism of IMA formation and the precise entity being measured are not fully known. Nevertheless, IMA measurement remains the only current clinical biomarker which may be used for the diagnosis of patients suspected of cardiac ischemia.

Keywords - Ischemia, Albumin, Biomarker, Ischemia modified albumin, Albumin Cobalt Binding Assay, Acute myocardial syndrome.

Introduction:

Ischemia occurs due to deficiency in the cardiac blood flow, leading to deficiency of oxygen and nutrients, and so affecting their vital functions. If Ischemia is reversible, no myocardial damage occurs. Necrosis of the cell and myocardial ischemia results if the ischemia is irreversible. Manifestations of myocardial ischemia differs like chest pain, epigastric or arm discomfort , breathlessness , nausea and vomiting. However the ultimate challenge in medicine is to identify myocardial ischemia before necrosis has occurred. There is a need for early and sensitive markers of cardiac ischemia as. The current diagnostic tests fail to identify many chest pain patients and who are at a high risk for adverse cardiac diseases, hence there exists a need to identify certain markers of cardiac ischemia. Cardiac markers of cell necrosis such as myoglobin, CK-MB and troponins are highly sensitive and exhibit good specificity. However they do not detect myocardial ischemia in the absence of necrosis[1,2] .

Various biomarkers used in detection of myocardial infarction are as follows : Myeloperoxidase, MMP-9, sCD40L, Pregnancy associated plasma protein A, Choline, Ischemia modified albumin, unbound free fatty acids, Glycogen phosphorylase isoenzyme BB, Placental growth factor. Recently, a new biomarker has been developed Ischemia modified albumin(IMA). IMA is produced during an ischemic attack and present in blood in easily detectable concentrations. This review will highlight the role of albumin as a biochemical marker in acute myocardialsyndrome.

Mechanism of production of IMA:

The N-terminal portion of human serum albumin (HSA) is a binding site for transition metal ions such as cobalt, copper and nickel[2] . Many divalent metals bind HSA in the circulation but in concentrations far lower than that required to impact albumin directly. The N-terminal portion of HSA has higher chances of biochemical degradation and has less stability than the albumin of other species[3] . IMA is a form of HSA in which the N-terminal amino acids are unable to bind to transition metals. Myocardial ischemia generates free radicals [4,5] acidosis develops [6] and release of free iron and copper ions occurs [7,8]. HSA is a scavenger for divalent metal ions. It may thus be postulated that in ischemia, these processes may result in change in the ability of the N-terminus to bind to transition metal ions. The release of these ions

likely initiates one potential pathway for IMA generation and thus need not be considered interference to negatively affect IMA. The postulated mechanism is that localized ischemia results in acidosis and the release of copper II from weak binding sites on circulating proteins. Ascorbic acid which acts as a reducing agent converts free copper II to copper I and reacts with oxygen to form copper II which generates superoxide free radicals. Superoxide dismutase converts the superoxide free radicals to hydrogen peroxide which is then degraded by catalase. Copper II ions released are immediately scavenged by albumin but are tightly bound to the N terminus. Copper bound albumin is then damaged by hydroxyl free radicals, causing removal of the three N terminal amino acids and release of copper II ions to repeat the process in a chain reaction [9] . An increase in IMA was observed in patients minutes after transient occlusion and reperfusion during coronary angioplasty [10,11] .

Clinical interpretation of IMA:

The use of biomarkers for the identification of suspected acute coronary syndromes depends on the presence of myo necrosis as a surrogate indicator for myocardial ischemia. It has been reported that in the setting of myocardial ischemia, there are modifications to the amino acids of the N terminus of the human albumin molecule. These modifications alter the N-terminus in such a way that it can no longer bind transition metals, such as cobalt [12] From this observation, an assay measuring the ability of albumin to bind cobalt was developed, which has been suggested to be useful for the detection of myocardial ischemia. In experimental models and in clinical studies, IMA has been shown to rise within minutes after the onset of ischemia, stay elevated for 6 to 12 hours, and return to normal within 24 hours [13,14] . Furthermore, IMA has been shown to predict with high sensitivity subsequent elevation in the troponins in the clinical setting [15].

Aslan D et al determined reference values of IMA from a population of 283 healthy individuals and ranged from 52 to 116 kilounits/L, with a 95th percentile at 85 kilounits/L [16] . While the optimum cutoff for IMA for ruling out ACS is 85 kilounits/L, a higher value of 100 kilounits/L is suggested for risk stratification. IMA is normally distributed in a group of apparently healthy volunteers and is not correlated with smoking, age, race, gender, or Framingham risk score. IMA is not specific for cardiac ischemia. IMA has an elevated level in

most patients with cirrhosis of liver, advanced cancers and acute stage infections; all these conditions produce free radicals of considerable quantity. IMA seems to be produced in patients with brain ischemia (stroke), end-stage renal disease and intrauterine ischemia [17,18] . Data exist suggesting that very low albumin levels and the presence of co-existing lactic acidosis might affect assay performance [19,20] . Additional data are needed to clarify the impact of total albumin alterations on IMA interpretation. Moreover, the ACB test is an indirect measure of IMA and such albumin has not yet been isolated [21] . An immunochemical assay, which would improve the analytical sensitivity of the test but might not have an impact on the clinical specificity, has not yet been developed.

Clinical applications of IMA:

IMA as a marker of supply ischemia:

Ischemia detection is very difficult to detect prior to infarction and remains as a challenging concept. It would be very helpful to be able to identify quickly and accurately which patients really have myocardial ischemia and may be in need of either treatment or intervention to prevent subsequent events. In clinical trials use of IMA has performed reasonably well, focusing on its capability for early measurement to characterize acute coronary syndrome patients. Blood levels of IMA rise promptly during myocardial ischemia triggered by a primary reduction of blood flow (supply ischemia), as seen in patients undergoing percutaneous coronary intervention (PCI), stay elevated for about 6 hours and return to baseline within 12 hours [22,23,24] In a previous report, IMA production was decreased in patients with collateral vessels, which is likely to be a protective effect of collateral circulation against PCI-induced myocardial ischemia-reperfusion injury [23] . IMA levels and objective markers of ischemia such as lactate levels and isoprostane concentrations are believed to be in good correlation according to some studies in this setting [24] . Moreover, IMA was shown to increase significantly in patients undergoing intracoronary ergonovine spasm provocation test and may have a role as a biochemical marker for transient myocardial ischemia induced by coronary vasospasm [25].

However, as promising as the IMA assay appears some degree of caution is still suggested. The currently accepted strength of IMA lies in its negative predictive value for

excluding the presence of ischemia. Unfortunately, predictive values cannot necessarily be translated into clinical practice; in reality, predictive value is less a measure of test performance than it is a reflection of disease prevalence in the population being tested. It is a basic principle of diagnostic testing that adding tests together increases sensitivity. Thus, adding IMA to traditional markers will increase sensitivity, but so would adding other biomarkers. In this manner, specificity will be reduced, leading to an even higher false-positive testing rate. Nevertheless, IMA currently remains the only ischemia assay to have reached the clinical validation stage. For efficient provision of care in the Emergency Department, a high negative predictive value may be critical, because the correct exclusion of ACS preserves limited and expensive resources, such as stress tests, hospital beds and catheterization slots [26].

IMA as a marker of demand ischemia :

A number of studies have demonstrated that exercise may induce perturbations in circulating IMA levels [27-34] . In a study the IMA concentration has been shown to decrease immediately post race followed by an elevation 24-48 hours post exercise in 19 healthy marathon runners [28] . Similar findings were confirmed by additional reports assessing IMA levels in healthy individuals following completion of high workload exercise [29] . The IMA has also been evaluated in healthy subjects following hand grip and was found to decrease significantly after forearm ischemia and to return to baseline thereafter; similar changes were reported for the IMA:albumin ratio. However, Falkensammer et al reported a significant increase in circulating IMA concentrations in 12 healthy volunteers after exercise induced calf-muscle ischemia [30] . In the same study a significant negative correlation was found between IMA and albumin, but no association of IMA levels with lactate was observed. It is clear that there is no homogeneous response in exercise-induced changes of IMA. Exercise results in a number of potential ischemic sites, such as skeletal muscle or gastrointestinal tract. It seems that the hemoconcentration that occurs during physical exercise induces an increase in albumin plasma levels and, consequently, a decrease in the non-bound portion of a fixed amount of cobalt. Still one should also take into account that myocardial ischemia during a stress test may be different in either physical or pharmacological stress and may not be as severe as the ischemia that occurs during angioplasty or in the ACS settings. Lactic acidosis can also interfere with the analysis of IMA as there is a negative correlation between them. Hence, significant care must be taken in the interpretation of

post-exercise IMA data. Elucidation is required to understand the mechanism for detectable transient changes of IMA in response to demand ischemia. To date, there is no approval for use of this test in conjunction with a stress test. Standardized and rigid protocols are required for clinical assessment of IMA after ischemic exercise and sampling time points and similar study populations.

IMA as a marker of myocardial injury:

IMA has been evaluated as a potential indicator of transient myocardial ischemia in different clinical models of myocardial injury. Radiofrequency (RF) catheter ablation is a widely used treatment for cardiac arrhythmias but results in a detectable injury to the myocardium, which is unrelated to ischemia-reperfusion injury per se [35] . Moreover, any changes in IMA in association with RF ablation cannot be attributed to albumin variations because albumin levels are not expected to vary in relation to this procedure. Several researchers found that IMA plasma levels did not change immediately after, 2 and 20 hours after RF ablation compared to baseline values, whereas CK, CK-MB and troponin I increased significantly compared to baseline [36]. However, a previous report on IMA in RF ablation showed that IMA significantly increased 30 min after the procedure and returned to baseline values in 8 hours [37] . The different timing may explain the contradiction between the latter study's findings and ours, although the effects of ischemia on the N-terminal region of albumin can be detectable up to 6 hours after the ischemic event. There is one study reporting that IMA plasma levels increase 1 and 6 hours following cardioversion in patients with AF, along with an increase of CK and CK-MB; [38] it may be that cardioversion produces skeletal damage at the proximal site of shock applications, along with cardiac ischemia in the more distal cardiac tissues. Transvenous lead implantation of either permanent pacemakers or defibrillators induces minimal myocardial injury, expressed as a rise in cardiac troponins, which are very sensitive and specific markers of myocardial cell necrosis [35] . E. Sbarouni et al found that IMA and CK increased at 6 and 48 hours after permanent pacemaker/defibrillator implantation compared to baseline values, whereas CK-MB and troponin I increased at 6 hours and returned to baseline at 48 hours [39] . These data suggest that insertion of endocardial leads is accompanied in most patients by minimal necrosis. This seems to be preceded by transient ischemia, as shown by a significant increase in IMA levels, which could be attributed to myocardial ischemia. Despite the lack of evidence in the aforementioned clinical

situations, it could be speculated that the underlying mechanism may be the damage to the N-terminus by reactive oxygen species or disruption at the cellular level. Recently, IMA has been described as a useful discriminative marker to exclude pulmonary embolism, which is known to be associated with right ventricular dysfunction and myocardial ischemia [40] . The serum IMA levels of 30 patients with definitively diagnosed pulmonary embolism were significantly higher than those of 30 healthy volunteers[41].

Measuring IMA:

Albumin cobalt binding test:

IMA was measured by the albumin cobalt binding test (ACB Test) on the Roche Cobas MIRA PLUS instrument. The mechanism whereby IMA represents a marker of ischaemia is based upon the fact that human serum albumin (HSA) has the ability to bind certain transition metal ions, particularly cobalt and copper, at the N-terminus. The structure of HSA N-terminus changes after exposure to albumin such that it can no longer bind cobalt was previously reported by Bar-Or [12,41]. Blood was collected for the IMA test in serum separated tubes. Specimens were frozen at 220°C or colder within two hours. Frozen samples were gently vortexed after thawing. Specimens handled in this way showed no significant
difference in assay results from the fresh specimens. In the ACB Test, 95 ml of a patient sample and 5 ml of cobalt chloride (CoII), are incubated for five minutes. During incubation, the Co(II) binds to the N-terminus of unaltered albumin in the sample; albumin for which the N-terminus is altered as a result of ischaemic processes binds to the Co(II) to a far lesser extent. After incubation, 25 ml of dithiothreitol (DTT) is added to the mixture. DTT forms a coloured complex with Co(II) that is not bound at the N-terminus of albumin, and this complex is measured spectrophotometrically at 500 nm. The mean recorded as the result of the assay was used to obtain duplicate IMA values The assay is based on the premise that myocardial ischemia causes changes in human serum albumin (HSA) that are demonstrated by reduced exogenous

cobalt (II) binding. A known amount of cobalt (II) is added to a serum specimen and measurement of the unbound cobalt (II) by colorimetric assay using dithiothreitol (DTT) is used to determine the concentration of ischemia modified serum albumin. An inverse relationship thus exists between the level of albumin bound cobalt and the intensity of the color formation [42].

Prognostic value of IMA :

In the early hours of ACS, selection of patients who are at high risk for cardiac events is an important factor in determining the appropriate treatment strategy. The use of serum IMA concentrations for the early prediction of adverse clinical outcomes in patients with suspected ACS has only recently been the subject of investigation, but shows controversial results. Worster et al enrolled 189 patients who presented to an Emergency Department within 6 hours after chest pain, seeing an emergency physician who ordered a cTn-I test, and who had no serious cardiac outcome before the troponin result became available [43]. Of the 189 patients, 24 had a serious cardiac outcome within 72 hours after their arrival at the Emergency Department. The timely ratios for measurement of IMA within 6 hours after chest pain predicting a serious cardiac outcome within the next 72 hours were 1.35 (95% confidence interval [CI] 0.315-5.79) for IMA≤80 Units/mL and 0.98 (95% CI 0.86-1.11) for IMA>80 Units/ mL. Although these data suggest that IMA is a poor predictor of serious cardiac outcomes in the short term, they may be explained by taking into account the following:

Elevation of IMA is non-specific and hence may induce any prognostic significance if it is used for prognosis before first establishing the diagnosis. Post-PCI IMA elevation more than 130 kilounits/L was associated with higher target lesion revascularization at nearly 4-years follow-up (p=0.026)[44]. Interestingly, in patients with ST segment elevation myocardial infarction treated with PCI and who developed heart failure, IMA levels were significantly associated with a decreased left ventricular ejection fraction, representing an early marker of left ventricular dysfunction.[45]

IMA levels vary considerably, even among healthy individuals, and taking these variations into account may improve the predictive characteristics of IMA. Aparci et al have also investigated the prognostic significance of IMA in patients with ACS. IMA was found to be significantly related to 1-year mortality but with a cut-off value of 477 Units/mL. The prognostic

significance of IMA needs be evaluated in large populations and randomised study groups before it can be used for risk stratification in patients with ACS.

Conclusion :

The remarkable increase in the discovery of new biomarkers demands great attention to their assessment before clinical application. The value of IMA lies in its negative predictive value for excluding the presence of ischemia in a population with a low prevalence of coronary artery disease. Rather than providing evidence of ischemia, perhaps its greatest role will be reassurance. Although, this marker is not very specific, it is highly sensitive when negative. An elevated level of IMA also appears to be an outcome predictor which is an interesting thought. Before changing clinical practice, meaningful studies addressing utility, outcomes and cost-effectiveness need to be conducted. “Crossing the boundary from research to clinical application,will require replication in multiple settings, experimental evidence supporting a pathophysiologic role, and ideally, intervention trials demonstrating that modification improves outcomes” .

Abstract

Alcohol is the ingredient found in beer, wine and spirits which causes drunkenness. It is formed when yeast ferments the sugars in different foods. For example, wine is made from the sugar in grapes, beer from the sugar in malted barley, cider from the sugar in apples, and vodka from the sugar in potatoes, beets or other plants. This paper provides a brief overview of the health and body effects of alcohol. Various areas covered include the effects of alcohol on body parts, health effects of acute alcohol use, and health conditions related to chronic alcohol use. The aim of this review is to know about alcoholism and its ill effects.

Key Words : *alcoholism,withdrawal,cirrohosis of liver*

Introduction

Alcohol is classed as a sedative hypnotic drug [1, 2] which meansit acts to depress the central nervous system at high doses. At lower doses, alcohol can act as a stimulant inducing feelings of euphoria and talkativeness, but drinking too much alcohol at one session can lead to drowsiness, respiratory depression, coma or even death[3].If alcohol consumption is acute and potentially lethal sedative effect at larger doses, alcohol has influence on all organ in the body, and these effects depend on the alcohol blood concentration.[4]. In a medical context, alcoholism is said to exist when two or more of the following conditions is present: a person drinks large amounts over a long time period, find difficulty in controlling, acquiring and drinking alcohol will take up a more time.Alcohol is strongly desired, usage results in not fulfilling responsibilities, usage results in social problems, usage results in health problems, usage results in risky situations, withdrawal occurs when stopping, and alcohol tolerance has occurred with use.[5] Risky situations include drunken drive or having unprotected sex with multiple partners, among other things.After a drink is swallowed, the alcohol is rapidly absorbed into the blood: 20 % through thestomach and 80 % through the small intestine), with effects felt within 5 to 10 minutes after drinking. It usually peaks in the blood after 30 to 90 minutes,and thus is carried through all the organs of the body [6, 7].Liver performs 90 % of the metabolismor breakingdown, of alcohol from a toxic substance to water and carbon dioxide,and therest excreted through the lungs, through the kidneys and via sweat.Only a certain amount of alcohol can be breakdown per hour, in which for an average personis around one standard drink which raises the blood alcohol concentration about 15 to 20 mg/dL [8]. Alcohol use can affect all parts of the body, but it particularly affects the brain, heart, liver, pancreas, and immune system. This can result in mental illness, Wernicke–Korsakoff syndrome, an abnormal heartbeat, liver cirrhosis, and an increase in the risk of carcinoma, among other diseases.Drinking during pregnancy can cause damage to the baby resulting in fetal alcohol spectrum disorders. Women are generally more sensitive than men to the harmful physical and mental effects of alcohol.[9]

Reasons for alcoholism

Many factors can increase the risk of alcohol abuse. People may become alcoholic forseveralreason and gradually develop a dependency on drinking. For example, consuming

alcohol during difficult times like death in the family or job loss can potentially trigger long-term alcohol abuse.

Relieve stress

Relying on alcohol to reduce stress that occur everyday,may impact the likelihood of developing alcoholism. Since alcohol is a depressant and a sedative, drinking produces feelings of pleasure. However, frequent drinking builds tolerance, requiring you to consume more alcohol in order to achieve the same effects.

Feel good

Consuming alcohol can provide some people a break from reality. It offers a sense of relief from underlying issues your mind may be trying to escape from. However, continual alcohol use to get through the day or week can turn into a serious drinking problem [10].

Cope with loss

Losing a family member or friend can take a toll on you emotionally, physically and mentally. Alcohol can ease the feeling that people hav and is used to get through the tough times. Depending on alcohol, even temporarily, can spiral into a drinking problem.

Overcome anxiety

Fewindividuals are naturally anxious, causing them to worry. Drinking lowers an individual's inhibitions and makes them more comfortable in social situations. Over time though, this can lead to addictive behaviors [11].

Body effects of alcohol

Concentration of blood rises and the feeling of drunkenness occurs, when alcohol is drunk faster than the liver can break it down. The higher the blood alcohol concentration, the greater the effects on the body.

However, blood alcohol concentration won't relate exactly with symptoms of drunkenness and various people have different symptoms even after drinking the same amount of alcohol.

The blood alcohol concentration level, and every individual's reaction to alcohol, is influenced by [12]:

• The ability of the liver to metabolise alcohol

• The presence or absence of food in the stomach

• The concentration of alcohol in the beverage

• How quickly alcohol is drunk

•Age, sex, ethnicity, body type

•How frequently a person drinks alcohol

Overall body effects

Alcohol intake can affects all body parts which includes:

• Blood and immune system
• Bones and muscles
• Brain and nervous system
• Breasts in women
• Eyes
• Heart and blood pressure
• Intestines
• Kidneys and fluid balance
• Liver
• Lungs
• Mental health
• Mouth and throat
• Pancreas and digestion of sugar
• Sexual and reproductive system in men
• Sexual and reproductive system in women
• Skin and fat
• Stomach and food pipe

Health conditions related to chronic alcohol use

For some people, alcohol is a regular or occasional drink enjoyed at social occasions that causes no apparent harm. However, even moderate alcohol use carries some risks, as alcohol causes breast cancer even at low doses, can damage the developing fetus before a woman even knows she is pregnant and can lead to addiction and dependence in any individual. When drunk regularly over time and/or drunk in a pattern of heavy single drinking sessions, alcohol can cause a variety of health conditions. These include carcinoma and other disease which include as alcoholic liver disease, which can present from reversible to permanent liver damage due to alcohol. The risks of alcohol-related cancers and other health conditions caused by alcohol are greatest in those who are dependent on alcohol or drink heavily, and the risks increase with the average amount of alcohol drunk [12].

The Harmful Effects of Alcohol

Harms Associated With Alcohol

Alcohol abuse is a major factor in death, disease, accidents and crime in Australia. The problems associated with alcohol use generally fall into two areas:

- Short-term harm due to intoxication called as binge drinking
- Long-term harm due to alcohol dependence

Binge Drinking

Binge drinking occurs when a person drinks heavily over a short period of time resulting in immediate and severe intoxication. Binge drinking is sometimes defined as ‘drinking to get drunk’. The health risks associated with binge drinking include the potential to develop toxic damage to the small bowel which causes diarrhoea, depression of the central nervous system, hangovers, headaches, and stomach problems resulting in nausea, shakiness and vomiting. Importantly, because intoxication stops one thinking clearly and acting sensibly, binge drinking can also lead a person to put themselves and others at risk of harm from other things. For instance, injury due to falls, risky behaviour or assault. It is for this reason that alcohol is closely associated with road accidents, fights and violence, coercive sexual activity and unprotected sex.[13]

Alcohol Poisoning

Serious binge drinking can lead a person to suffer alcohol poisoning. This occurs when the blood alcohol level rises to a dangerous point. At very high blood alcohol levels, a person may fit, lose consciousness and slip into a coma. There have been cases when the person intoxicated dies. Death from alcohol poisoning usually occurs in one of three ways:

• The blood alcohol level reaches such a high level that the depressant effects of the drug slow down the parts of the brain and nervous system that control breathing and the heart. Usually the drinker dies because they have stopped breathing and their heart has stopped, usually while unconscious [14]

• While unconscious, the drinker has been sick and choked on their own vomit. There are also rare reports of an unconscious drinker choking on their own tongue.

• The alcohol reacts with another drug that the person has taken. This can be either a prescription drug, over the counter medication or an illicit substance. These deaths are even more unpredictable as they can happen at a relatively low blood alcohol level. It is also important to be aware that an intoxicated person can also die of exposure in comparatively warm temperatures. Alcohol affects the body's thermostat, as well as the drinker's perception as to what is hot or cold, therefore someone who has been drinking can feel quitewarm when in fact their body temperature is dropping sharply[15]

Alcohol Dependence

While drinking a small amount of alcohol is generally not harmful for most people, regular drinking of a lot of alcohol can cause health, personal and social problems for a person over the long-term.People who drink heavily may become dependent on alcohol.[16] There are degrees of dependence, from mild dependency to compulsive drinking often referred to as 'alcoholism'. Alcohol dependence can be a physical problem, or psychological, or both.

For instance, to some degree many of us are psychologically dependent on alcohol if we feel that we cannot socialise at a party without a drink. In the case of an alcoholic person who is both physically and psychologically dependent, alcohol becomes central to their life. Such a person would suffer withdrawal symptoms such as, tremor, nausea, anxiety, depression, sweating, headache and difficulty sleeping, if they were to try to stop drinking or to cut down the amount they drink.

Alcohol Effect on Saliva

Saliva is a aqueous fluid containing organic and inorganic products secreted by salivary gland.Saliva is helpful in mastication, speech, deglutition, lubrication and mucosal protection.Decreased salivary flow rate may lead to dental caries, oral pain and fungal infection.Alcohol diffuses rapidly into saliva during the drinking. Then salivary concentration becomes temporarily higher than in plasma. Within half an hour, salivary alcohol concentration equilibrates with the alcohol level in plasma. This suggests that alcohol can easily penetrate the whole body, including salivary glands. The alcohol metabolizes to aldehyde. After alcohol intake, acetaldehyde level in saliva exceeds the level in blood. Damage to the oral tissues is possibly due to the action of acetaldehyde [17].

Alcohol Effects on Local Anaesthetics

Alcohol affecting the efficacy of local anesthetic depends of the dosage and quantity. Alcohol ingestion use to relieve pain has proven to be relevant but as the body develop tolerance and addiction towards the alcohol, patient have to increase the dosage and quantity to achieve analgesic property. To achieve analgesic property, orally administered ethyl alcohol (1ml/kg of 100% ethyl alcohol + 1ml/kg tonic water) produced tolerance to pain comparable to 0.17mg/kg s.q. morphine. 10.[18]

Alcohol and Its Effects

Alcohol is absorbed directly into the bloodstream through the stomach and the small intestine. Food in the stomach slows down the rate at which alcohol is absorbed, but does not prevent intoxication or drunkenness. All alcohol consumed will reach the bloodstream, regardless of how much food is in the stomach. Alcohol is distributed throughout the water in the body, but not into fatty tissue .

The liver breaks down about 91 per cent of alcohol, and a small amount leaves the body in urine, sweat and the breath. The liver can only work at a fixed rate, getting rid of about three-quarters of a standard drink an hour. Sobering up takes time, and cold showers, exercise, black coffee, fresh air or vomiting will not speed up the process. Someone who drinks a lot at night may still have a high concentration of alcohol in their bloodstream the following day .

Immediate Effects

After a few drinks, the person may feel more relaxed, have reduced concentration and slower reflexes. After a few more drinks, they may have fewer inhibitions, more confidence, reduced coordination, slurred speech and intense moods.

If the person continues to drink, they may experience confusion, blurred vision and poor muscle control. Continuing to drink may result in nausea, vomiting and sleep. Consuming more alcohol could possibly result in coma or death.

Long Term Effects

Heavy consumption of alcohol over a long period of time can cause damage to many parts of the body. Impairment of brain and liver functions can be permanent. If the person's diet is also poor, this can further affect their health.

Emotional difficulties, such as depression and relationship problems, are also likely.Other possible long-term effects include:

- Cancer Of The Mouth, Throat, Oesophagus, Lips, Liver
- Brain Injury, Loss Of Memory, Confusion, Hallucinations
- High Blood Pressure Enlarged Heart And Changes In Rbc.
- Weakness And Loss Of Muscle Tissue
- Sweating, Flushing And Bruising Of The Skin
- Inflamed Stomach Lining, Bleeding And Stomach Ulcers
- Increased Risk Of Lung Infections
- Severe Swelling Of The Liver, Hepatitis And Cirrhosis
- Inflamed Pancreas
- Tingling And Loss Of Sensation In Hands And Feet
- For Men, Impotence, Shrinking Of Testicles And Reduced Sperm
- For Women, Greater Risk Of Gynaecological problems

Central Nervous System

One of the easiest ways to understand alcohol's impact on your body is by understanding how it affects your central nervous system. Slurred speech is one of the first signs you've had too much to drink. Alcohol can reduce communication between your brain and your body. This makes coordination more difficult.[18]. You may have a hard time balancing. You should never drive after drinking.As alcohol causes more damage to your central nervous system, you may experience numbness and tingling sensations in your feet and hands.Drinking also makes it difficult for your brain to create long-term memories. It also reduces your ability to think clearly and make rational choices. Over time, frontal lobe damage can occur. This area of the brain is responsible for emotional control, short-term memory, and judgement, in addition to other vital roles.Chronic and severe alcohol abuse can also cause permanent brain damage. This can lead to Wernicke-Korsakoff syndrome, a brain disorder that affects memory.

Sexual and Reproductive Health

You may think drinking alcohol can lower your inhibitions and help you have more fun in bed. But the reality is quite different. Men who drink too much are more likely to experience erectile dysfunction [19]. Heavy drinking can also prevent sex hormone production and lower your libido.

Women who drink too much may stop menstruating. That puts them at a greater risk for infertility. Women who drink heavily during pregnancy have a higher risk of premature delivery, miscarriage, or stillbirth.Women who drink alcohol while pregnant put their unborn child at risk. Fetal alcohol syndrome disorders (FASD) is a serious concern. Other conditions include:

- Learning Difficulties
- Long-Term Health Issues
- Increased Emotional Problems
- Physical Development Abnormalities

Skeletal And Muscle Systems

Long-term alcohol use may prevent your body from keeping your bones strong. This habit may cause thinner bones and increase your risk for fractures if you fall[19]. And factures may heal more slowly.Drinking alcohol may also lead to muscle weakness, cramping, and eventually atrophy.

Immune System

Drinking heavily reduces your body's natural immune system. This makes it more difficult for your body to fight off invading germs and viruses.People who drink heavily over a long period of time are also more likely to develop pneumonia or tuberculosis than the general population. About 10 percent of all tuberculosis cases worldwide can be tied to alcohol consumption. Drinking alcohol also increases your risk for several types of cancer, including mouth, breast, and colon[20]. Click here to learn the basics of alcoholism. You can also read about the stages of alcoholism and recognizing an addiction.

Tolerance and Dependence

People who drink heavily usually develop a tolerance to alcohol. This means that they need to drink more to experience the same effect. As a result, some people can drink large amounts of alcohol without appearing to be intoxicated. However, the amount of alcohol consumed can still damage their health.

People who regularly drink heavily may become dependent on alcohol. Dependence can be psychological or physical, or both [21]. People who are psychologically dependent on alcohol find that drinking becomes far more important than other activities in their life. People who are physically dependent upon alcohol find that their body is used to functioning with alcohol present.

Alcoholism and Family

The effects of alcohol abuse can have an impact on not only the individual who drinks, but also on the entire family unit. Someone who abuses alcohol has a higher risk of divorce and a

higher risk of being involved in domestic violence. Even when a couple stays together, alcoholism puts a strain on the marriage relationship [22]. The spouse of an alcoholic may become co-dependents and start to cover up for the alcoholic. He or she may make excuses for the alcoholic spouse's behaviour, clean up messes left by the alcoholic, lie for the alcoholic, or take on added responsibility at work or home. By covering for the other person, the co-dependent spouse enables the alcoholic to escape the consequences of his or her alcoholism and remain in denial.

When a parent is an alcoholic, it can affect the children as well. Parental alcoholism effects include a higher risk of child abuse or neglect, a higher risk of later drug or alcohol abuse by the child, and long-lasting emotional trauma. The children of alcoholics may also be more prone to developing mental illness later in life.

Withdrawal

If a person who is physically dependent on alcohol suddenly stops drinking, they will experience withdrawal symptoms because their body has to readjust to functioning without alcohol. Alcohol withdrawal symptoms include:

Loss of appetite

- Nausea
- Anxiety
- Insomnia
- Irritability
- Confusion
- Tremors
- Sweating

In severe cases, alcohol withdrawal may cause convulsions, cramps, vomiting, delusions, hallucinations and even death [21,22] A person considering withdrawing from alcohol should first consult a doctor or other health professional.

Conclusion

There are a number of drug treatment options available. While abstinence may be a suitable treatment aim for some people, many programs recognise that for others this may not be possible or realistic. Most programs adopt strategies that have an overall aim of reducing the harms and risks related to the person's alcohol use. Some treatment options include counselling, withdrawal, detoxification and medication, pharmacotherapy. Residential and "out-patient" programs are available[23]. Treatment is more effective if tailored to suit a person's circumstances, and usually involves a combination of methods.

Abstract

Dental ceramics are a network of materials which helps in the easy understanding of their advances, composition build up and its various applications in dentistry. Metal ceramic restorations have been in use for about 3 decades now. This kind of restoration is being increasingly used due to its astonishing performance and decent esthetics. Due to the increased demand of better aesthetics and concern about the biocompatibility of metal, all ceramic material restorations were introduced.In the recent years, there have been immense developments in the properties and the manufacturing methods of the all ceramic materials. Steps are being taken to use more of all ceramic restorations when compared to the use of metal ceramic restorations. Research is being done in order to improve the properties of all ceramic materials which will provide better aesthetics and function of the restorations. There are various alloys of ceramics that have been developed. There have also been advances in the manufacturing methods of the ceramic materials. Various cements are used for specific types of ceramics which help in the longevity of the restorations. The aim of this review is to understand the various advances in the vast field of dental ceramic materials.

Key Words*: All Ceramics, Zirconium, Microstructure, Strength, Aesthetics.*

Introduction

Ceramic materials are best able to mimic the appearance of natural teeth. However, two obstacles have limited the use of ceramics in the fabrication of dental prostheses: 1) brittleness leading to a lack of mechanical reliability and 2) greater effort and time required for processing in comparison to metal alloys and dental composites. There have been developments in the processing methods of ceramic materials which has simplified the work of dental lab technicians and improved the quality and properties of the material. Due to this, there is an increase in the use of all-ceramic prostheses and restorations. Core materials are the basis of all-ceramic dental restorations, and a variety of them have been seen to be used for the same. Zirconia blocks are being provided by manufacturers which are then being converted into crowns and bridges using the CAD/CAM system. Zirconia is seen to have better mechanical properties when compared tometals;this is due to its microstructure.[1] The properties of conventional zirconia were further improved by the composite in nano-scale such as zirconia/alumina nanocomposite. There are various reactions of zirconia seen such as in low temperatures, it shows long-term stability, and it's bonding to porcelains and to cement, X-ray opacity and biocompatibility. Engineers generally develop the new material which is later put to practical use in dentistry. A material such developed is dental ceramics. In dentistry, ceramics are considered as nonmetallic, inorganic structures composed of oxygen with metallic or semi-metallic compounds. They are usually sodium, potassium, calcium, magnesium, aluminum, silicon, phosphorus, zirconium & titanium.[2] Dental ceramics are materials that are part of systems designed with the purpose of producing dental prostheses that in turn are used to replace missing or damaged dental structures.[3] Metal ceramic systems are those in which ceramic provides the aesthetics and metal provides the necessary strength due to its mechanical properties.[4] Some metals used as restorative materials in dentistry may constitute a problem for some patients. These problems may reveal themselves as allergies,[5] gum staining[6,7] and release of metallic ions into the gingival tissue[8] and the gingival fluid.[9] These drawbacks, as well as the search for more esthetic materials by patients and dentists, have stimulated research and development of metal-free ceramic systems. The aim of this review is to understand the various advances in the vast field of dental ceramic materials.

Classification of Dental Ceramics

Dental ceramics can be classified in many different ways according to their: [10]

(a) Indication or use.

(b) Composition.

(c) Processing method.

(d) Firing temperature.

(e) Microstructure.

(f) Translucency.

(g) Fracture resistance.

(h) Abrasiveness.

Microstructural Classification

At the microstructural level, we can define ceramics by thenature of their composition of glass-to-crystalline ratio.The microstructures ofmaterials can come in various variability, but they are grossly divided into four basiccompositional categories, each having a few subgroups under them:

• Composition category 1 – glass-based systems

• Composition category 2 – glass-based systems with fillers, usually crystalline

• Composition category 3 – crystalline- based systemswith glass fillers and

• Composition category 4 – polycrystalline solids

Classification Based on Processing Technique

In general, for dentistry, they can be classified as:

a. Powder/liquid, glass-based systems,

b. Machinable or press able blocks of glass-based systemsand

c. CAD/CAM or slurry, die-processed, mostly crystalline(alumina or zirconia) systems.

1. Powder Condensation

In this technique, moist porcelain is applied using a special brush. The porcelain is then compressed by removing the excess moisture. This is then placed in a vacuum which causes further compression of the porcelain. Powder condensation uses feldspathic porcelain.

Feldspathic porcelain: It is a mixture in which potassium and sodium feldspars occur naturally. These are composed of potash (K2O) and soda (Na2O) respectively. Alumina (Al2O) and soda (Na2O) are also seen in trace amounts. Leucite and a glass phase are formed when potassium feldspar is fired to high temperatures. This glass phase softens during firing allowing coalescence of the porcelain powder particles. This process is called liquid phase sintering. This process forms a dense solidwhen kept in a high temperature. Since leucite has a large coefficient of thermal expansion, it is added to some glasses to control their thermal expansion.[11]This method results in a large amount of residual porosity. The crystalline particles that strengthen the material on a microscopic scale are not connected to each other but are separated by glassy regions. The porosity and discontinuous nature of the crystalline phase lead to relatively low strength and a wide variation in strength. Ceramics fabricated by powder condensation have greater translucency than can be achieved using other methods [12], so these materials are usually applied as the aesthetic veneer layers on stronger cores and frameworks.

2. Slip Casting

A slip is a low viscosity slurry or mixture of ceramic powder particles suspended in a fluid which is generally water. Slip casting involves forming a mold or negative replica of the desired framework geometry and pouring a slip into the mould. The mold is made of a material generally gypsum that extracts some water from the slip into the walls of the mold through capillary action, and some of the powder particles in the slip become compacted against the walls of the mold forming a thin layer of green ceramic that is to become the framework. The remaining slip is discarded, and the framework can be removed from the mold after partial sintering to improve the strength to a point where the framework can support its own weight. The resulting ceramic is very porous and must be either infiltrated with molten glass or fully sintered before veneering porcelain can be applied. Ceramics which are fabricated by slip casting is seen to strengthen the crystalline particles which forms a network thereby creating a higher fracture resistance. Use of this method in dentistry has been limited to one series of three products for glass infiltration (In-Ceram, Vita Zahnfabrik). The limited application of slip casting in dentistry is probably because the method requires a complicated series of steps, which provide a challenge to achieving accurate fit and may result in internal defects that weaken the material from incomplete glass infiltration [13].

3. Hot Pressing

Molds for pressable dental ceramics are formed utilizing the lost wax technique. Glass-ceramic ingots are used as pressable ceramics. The composition of the ingots is similar to that of the powder porcelains, the only difference being that they show less porosity with more crystalline content. The ingots are heated to a high temperature where they become a highly viscous liquid, and then pressed slowly into the formed mold. The advantage of this technique is that it utilizes the experience that the lab technician already has in lost wax method with metal alloys. Pressable ceramics are available from manufacturers as prefabricated ingots made of crystalline particles distributed throughout a glassy material. The microstructure is similar that of powder porcelains, however, pressable ceramics do not contain much porosity and can have a higher crystalline content because the ingots are manufactured from non-porous glass ingots by applying a heat treatment that transforms some of the glass into crystals. This process can be expected to produce a well controlled and homogeneous material. In the dental laboratory, the pressable ingots are heated to a temperature at which they become a highly viscous liquid, and they are slowly pressed into the lost wax mold. The advantage of hot pressing is that dental technicians are already experienced at achieving good accuracy of fit using the lost wax method with metal alloys [14]. Contrary to intuition, the higher crystalline content and lack of porosity do not lead to increased fracture resistance or decreased variability of strength [15]. Pressable ceramics usually have application only as core and framework materials. Pressable veneering materials, such as IPS e.max ZirPress (Ivoclar-Vivadent) are available, but the depth of layered esthetics may be limited when using pressable ceramics for veneering materials.

4. Computer-Aided Design

Like pressable ceramics, CAD-CAM ceramics are available as prefabricated ingots. These ingots are milled or cut by computer-controlled tools. After the tooth preparation is completed, an optical impression is taken by the use of an optic scanner.[16] The image is then transferred to the system’s software. Then the software designs the restoration and sends the data to the computer controlled milling machine that grinds the ceramic block according to the desired shape. In the case of presintered ceramics, the ingots are porous, which enables fast milling

without bulk fracture of the ceramic. The disadvantage of presintered ingots is the need for subsequent sintering treatment to eliminate the porosity. The computer software must compensate for the shrinkage that occurs during sintering to achieve good accuracy of fit. Densely sintered ceramics are available in non-porous ingots, which are more difficult to mill, but they do not require any further sintering. Glass infiltrated CAD-CAM ingots have similar composition to slip cast ceramics, but starting with a porous ingot eliminates the complicated steps of slip casting. After milling, the porosity is eliminated by molten glass infiltration. Dental CAD-CAM systems have been available for 20 years. In recent years, the increasing use of polycrystalline alumina and zirconia as framework materials and the increasing popularity and variety of CAD-CAM systems seem to be mutually accelerating trends.[17]

Properties

Strength and Fracture Toughness

There are two interrelated properties that often are quotedregarding ceramics intended for structural purposes:

a. Strength and

b. Fracture toughness

Strength

Mechanical failure of ceramic materials is almost completely controlled by brittle fracture. Usually, this brittle behavior combined with surface flaws resulted in relatively low ceramic strengths. Increased crystalline-filler content within the glass matrix, with a more even distribution of particles and finer particle size, has yielded significant improvements in the flexural strength of ceramic materials.[18,19] However, strength improvements are still limited by the inherentweakness of the glass matrix. All ceramics fail because of crack propagation at a critical strain of 0.1%.[20] Applied stresses can cause a crack to grow throughout the matrix, causing the ultimate failure of that restoration.

Fracture Toughness

A more important physical property is fracture toughness, which has been reported to be between 8 MPa m1/2 and 10 MPa m1/2 for zirconia. This is significantly higher than any previously

reported ceramic, and roughly twice the amountreported for the alumina materials. Fracture toughness is a measure of a material's ability to resist crack growth (i.e., a measure of the amount of energy necessary to cause crack growth). Clinically, restorations are not loaded to failure as is done in a flexural strength test; instead, millions of subcritical loads (chewing) are applied. Materials ultimately fail because of this cyclic fatigue by crack propagation.Thus, materials with higher fracture toughness are more ideal clinically as it takes more energy to cause crack growth. Other factors such as stress corrosion (chemically assisted crack growth) and residual flaws in the materialgreatly affect the final strength of a finished material.[21,22]

Contraindications of All Ceramic Restorations

1. Heavy occlusal forces: Ceramic restorations should be avoided in patients with parafunctional habits such as bruxism because of the brittle nature of the material and also its abrasive potential.
2. Inability to maintain a dry field: ceramic restorations require good moisture control at the time of their cementation to ensure positive outcomes.
3. Deep subgingival preparations: this is not considered an absolute contraindication, although supragingival preparations are desirable to produce a more accurate recording during impression taking. [23]

Aesthetic Considerations

Achieving a lifelike match requires the clinician/technician to choose a base ceramic having an appropriatetranslucency for thepatient. For a single anterior tooth, all ceramics havesufficient longevity based on clinical trial data, so thechoice can be made on aesthetic capability alone. Ceramic restorations give the teeth a natural tooth appearance.[24]Ceramic materials show a range of optical behaviors which changes from system to system, thus care must be taken when selecting which system to use.[25]Ceramic systems are capable of adjusting the levels of translucencyand control the colour. These are best learned byclinical practice.

Factors Contributing To Restorative Success

Restorative success depends on various factors and not just on the type of ceramic used.It is known that the tooth preparation for an all ceramic restoration must have rounded line angles

along with the finish line being a deep chamfer or a 90° rounded shoulder. If the restoration is going to be bonded, supragingival margins are preferred. Subgingival restorations cannot be done as it would be impossible to isolate these preparations. In such cases, the conventional cementation method is preferred. Sufficient occlusal reduction is required to be done in order to provide enough bulk to the ceramic restoration. Metal-ceramic restorations are preferred in cases where there is restricted interocclusal distance. Metal of the metal ceramic is seen to be placed in the lingual or occlusal surface. In addition to ensuring sufficient room for the foundation, it is also necessary to provide adequate resistance and retention form.Aesthetics can be increased when there is either a dark underlying tooth or metallic core. This is generally done in case of using alumina or zirconium. A feldspathic jacket, leucite-reinforced glass ceramic, or glass-infiltrated magnesium aluminum can be used in cases where high translucency of the restoration is required.All ceramic restorations can be provided to patients with parafunctional habits only after careful examination. If a patient insists on a metal-free restoration, the higher-strength core should be considered and occlusal guards used to prevent possible fractures. Attrition of the opposing tooth structure due to an opposing all-ceramic crown causes problems. The higher leucite-containing ceramics have a tendency for high abrasion potential.It is noted that anterior and posterior teeth require different materials as the amount of force during mastication is not the same for the two. Since the development of using cement to lute all-ceramic restorations has made indirect metal-free restorations can be done faster and more efficiently. Often, however, compromises must be made when clinicians and patients are faced with choosing between the ultimate aesthetics and function.

Effect on the Wearing of Opposing Dentition

In many individuals, tooth wear is a natural unavoidable process that is usually a result of tooth to tooth and/or tooth and restoration contact. Contact usually occurs when sliding movements are taking place. The process of wear essentially becomes accelerated by the introduction of restorations inside the oral cavity, and the rate of tooth surface loss is greater in case of opposing ceramic restorations. Wear of the entire dentition is possible without the presence of any restoration, and it should always be aimed for the hardness of restorative materials and their wear behaviour remains similar to that of natural enamel; otherwise, tooth surface loss may lead to a variety of clinical problems including damage to the opposing enamel structure, loss of occlusal

vertical dimension, problems in mastication, temporomandibular joint problems,hypersensitivity, and esthetic impairment.For many decades, ceramics have been used for esthetic restorations because of their excellent esthetic qualities and superior biocompatibility. However, ceramics are brittle in nature, require careful polishing techniques and are abrasive to the opposite dentition. There have been suggestions by authors that placement of ceramics over the occlusal surfaces should be avoided so that opposing dentition wear could be minimized. For that reason, modified ceramics have been developed recently in an attempt to decrease their wear characteristics.The newest materials have vastly contributed toward the interest in esthetic dental restorations. The effects of newly introduced dental ceramics have been extensively studied in laboratories. However, laboratory studies which test the abrasion resistance could produce results that are completely different for the same materials tested in clinical studies. In spite of the various technological advancements, there is no evidence on the clinical wear caused due to ceramics when it is restored opposing restored teeth and natural dentition.[26]

Cementation of All Ceramic Restoration

Resin-modified glass ionomer cements (RMGIs) or composite resins can be used for definitive cementation of all-ceramic restorations. The cements used can either be self-setting or sets by dual curing, where a light helps to set the cement at the margin of the restoration. It is recommended to use the adhesive technique with the light curing composite resin. Composite resin cements used today have a chemistry based upon our current generation of composite resins and bonding adhesives.[27] Resin-based cements include composite resin cements that are self-adhesive and self-setting or those that require an additional bonding adhesives used before the cement is placed. These cements can be light curing only, self-curing, or dual cured. The challenge to the chairside assistant for all-ceramic restorations is what steps are necessary both for pretreatment of the restoration and in preparation for cementation. Cements are available in different forms such as capsules which need to be triturated or they have to be mixed on a paper pad with a cement spatula. Most composite resin cements and some RMGI cements can be mixed by extruding from a double-barrel system into auto mixing tips. All the cements used for cementation has a consistency, viscosity and film thickness which is apt for cementing the all ceramic restorations. It should be noted that there is variability in the handling characteristics of each class of cement, and even differences within the same class of cement. It is critical that the

dentist and their chairside assistant read the instructions as it relates to material dispensing and mixing before it is used for cementing the restoration.[28] Cements are recommended so that they match the physical properties of the restorative material being used. It is important to follow the manufacturer's recommendations to achieve a clinically successful result.

Silicate Ceramics

Silicate ceramics have the property that when it is etched with hydrofluoric acid and bonded, the physical properties or porcelain is seen to be improved.[29] Silicate porcelains are very brittle in nature thus in function, they can develop small cracks which are known as microcracks. The use of adhesive composite resin cement strengthens the etched porcelain by interlocking into the microscopically roughened surface, not allowing the microcracks to propagate through the porcelain, which would create a fracture.Porcelain veneers are manufactured using from silicate ceramics. Silicate ceramics are found to be thinner and more translucent than oxide ceramics which helps in the easy etching and bonding to the tooth surface. Porcelain veneers is seen to be cemented best using light-cured composite resin cement. The composite resin cements come in packs that contain an etch-and-rinse adhesive which must be used first, followed by a porcelain primer and finally the light-cured cement in the shades that matched the ceramic must be used.Crowns which are fabricated from leucite-reinforced ceramics can be cemented using composite resin cements which may be in the light-cured, self-cured, or dual-cured type. Self-adhesive resin cements are typically not used. Lithium disilicate ceramics was seen to behigh-strength durable porcelain which soon overtook the use of leucite-reinforced ceramics. Lithium disilicate ceramic restorations can be cemented with any of the composite resin cements. Many lithium disilicate restorations are more slightly more opaque than leucite reinforced ceramics. Although veneers fabricated with lithium disilicate can be cemented with light-cured composite resin, it is not recommended that light-cured resin cement be used for crowns because of their greater thickness. Dual-cured, self-cured and self-adhesive resin cements can be used.

Oxide Ceramics

Oxide ceramics are fabricated with metal oxides. These ceramics are very resistant to fracture. Oxide ceramics are seen to be resistant to etching. Using specialized air abrasive aluminum oxide/silicate coated particles, sand blasting can be effective in making the surface more adhesive.[30] Cementation of oxide ceramics can be done with the same cements that are used for PFM restorations. Oxide ceramics which are also called as zirconia restorations, can be cemented with glass ionomer cements or composite resins. In the experience of the authors, the easiest cements to use with zirconia restorations are RMGIs and self-adhesive composite resin cements. Both these cements do not require etching or the use of a special bonding agent for the luting of the ceramic restorations. Some manufacturers provide a separate surface primer for the zirconia before using composite resin cement.

Repair

Approaches to the repair of porcelains have beenreviewed relatively recently.[15] Repair often offers bothdentist and patient a cost-effective alternative toreplacement. Repair involves the bonding of resinbasedproducts to remaining porcelain. The porcelainresinbond is formed by both etching the surface tocreate micromechanical attachment features and by theapplication of silane coupling agents to provide somechemical interaction between the silicon-based ceramicand carbon-based resins. It is reported that porcelainrepair systems form durable bonds to fractured porcelainand exposed metal surfaces.[31]

Conclusion

Ceramics have the property of showing the similar optical characteristics of enamel and dentine and thus are widely used in dentistry. Ceramics also has good biocompatibility andchemical durability. The new generation of ceramic materials presents interesting options, both in terms of material selection and in terms of fabrication techniques. A better understandingof the ceramic materials with respect to the restoration design and efficient use can enable these restorations to perform productively.

Abstract

This article describes the ceramic system and processing techniques available today in dentistry. It aims to help the clinician to understand advantages and disadvantages of ceramics. The properties ,classification, products gives us more idea about various options. The desire for beautiful teeth is a good reason to pay attention to the selection and quality of the restoration. In search for the ultimate aesthetics restorative materials, all ceramic system is the best choice among all the restorative materials. tremendous progress has been made in terms of mechanical performance, with a ten-fold increase in flexural strength and fracture toughness.

Key Words: *Ceramic, properties, classification, aesthetics, strength.*

Introduction

Replacement of a missing natural teeth was considered very important by mankind over all ages [1]. The earliest forms of materials used for replacement of missing teeth included wood, ivory, shells, etc.Over time, more attention was diverted towards replacement of the missing tooth that resembled the natural teeth. The first porcelain tooth material was documented by a Frenchdentist names De Chemant in 1789.Typically, they demonstrate excellent strength and hardness properties; however, they are often brittle in nature. Some ceramics like superconductors, also display magnetic properties.Ceramics basically consists of glasses, porcelain, glass ceramics or high crystalline structures. Ceramics are more resistant to corrosion than Plastics. Ceramics have gained their importance during the stone age more than 10,000 years ago, especially in human society.

The two main categories of ceramics are traditional and advanced. Traditional ceramics include objects made of clay and cements that have been hardened by heating at high temperatures. Traditional ceramics are used in dishes, crockery, flowerpots, and roof and wall tiles. Advanced ceramics include carbides, such as silicon carbide, SiC; oxides, such as aluminium oxide,nitrides, such as silicon nitride,and many other materials, including the mixed oxide ceramics that can act as superconductors. Advanced ceramics require modern processing techniques, and the development of these techniques has led to advances in medicine and engineering.

The entire thickness of the crown was 100% ceramic.All ceramic systems in dentistry have been developed for many decades.It provides maximum aesthetics to the restoration.Despite its success, the demand for improved aesthetics and the concerns regarding the biocompatibility of the metal has lead to all-ceramic restorations[2]. Dental ceramics are otherwise called as dental porcelain. They are non-metallic,inorganic structures primarily containing compound of oxygen with one or more metallic or more metallic or semi metallic elements[3]. What highlights the all ceramic system is their aesthetics and High durability. Ceramic are considered the best in mimicking the natural tooth appearance[4].The optical behaviour of ceramic materials differ from system to system and this should be taken into consideration during the selection of which system to be used[5].

Historically there were three types of ceramic materials - earthen wear,stone wear and porcelain. Earthenware is pottery that has not been fired to vitrification and is thus permeable to water[6].Stoneware is a vitreous or semi-vitreous ceramic made primarily from stoneware clay or non-refractory fire clay[7]. Stoneware is fired at high temperatures[8].It may or may not be glazed.[9]. It has high value of aesthetics. The first application was porcelain dentures. Interestingly porcelain is still quite widely used in dentistry.

At the beginning of the nineteenth century Charles Henry Land developed the porcelain jacket crown, based on a feldspathic composition, which is still used today in a slightly modified form. It had a very good aesthetics. Due to the low flexural strength of porcelain. It resulted in high incidence of failure. Vita Zahnfabrik developed the first commercial porcelain in 1963. Fifty years later, reinforcement of the jacket crown with aluminium oxide was achieved as a result of the work of McLean and Hughes [10].Dental ceramic shows a rapid growing field of interests as far as dental materials research is concerned. There is always demand existing for tooth coloured restoration. So future of ceramics appears very bright.

All ceramic systems are generally contraindicatedin situations such as: i) When there is a para-functional habit; ii) Inadequate support for the dental preparation; iii) It is not advisable as abutment bridge, unless it is placed on the anterior area and iv) When there is a pronounced overbite in the anterior area.The use of all ceramic is increasing day by day. But all ceramics systems are not all the same. They differs in the aesthetic potential. Despite its aesthetic and biocompatibility, there are failures existing due to their limited properties which are common to all ceramic crowns. The majority of all ceramic crowns are produced using computer technology, e.g. CAD/CAM technology which is based upon 3D design.

Classification

There are many types of dental ceramics which are available in dental laboratory which include core ceramic, Linuxceramic, marginceramic, opaque dentin ceramic, dentin ceramic, enamel ceramic, stain ceramic, glaze ceramic ceramic, and addition ceramic.

They are further classified according to –

- Use /indication

- Composition
- Processing method
- Firing temperature
- Microstructure
- Translucency
- Fracture resistance
- Abrasiveness

Based On Microstructure

I. Glass Based System With Silica

II. Glass based systemwith silica and fillers

a) low to moderate leucite containing feldspathic glass

b) high leucite

c) lithium disilicate

III. Crystalline based system with glass fillers.

IV. Polycrystalline solids.

Based On Processing Technique

- Powder/liquid glass based system
- Pressable blocks of glass based systems
- CAD/CAM systems

Based On Composition

- Silicate
- Oxide ceramics
- Glass ceramics

Based On Types

- Feldspathic Porcelain
- Aluminous Porcelain
- Reinforced Porcelain
- Glass Infiltrated Porcelain
- Glass Infiltrated Zirconia

- Glass Ceramic

Based On Temperature

- Ultra low fusing <850C
- Low fusing 850-1110C
- Medium fusing 1101C - 1300C
- High fusing >1300C

Based On Structure Metal

- Cast metal, glassceramic, sintered coated ceramic, and CAD-CAM.

Based On Reinforcement Method

- Reinforced ceramic core system, resin -bonded ceramics, metal ceramics.

Composition

Dental ceramics are usually made up of minerals called feldspar with added silica and fluxingoxides. Feldspar - K2oAl2O3SiO2,Albite-Na2O.Al2O3.6SiO2,Which is roughly consisting of 80% feldspar,15% silica ,4% clay. The main component is SiO2. There are minor components like Al2O2,MgO,ZiO2 and oxides. Ceramics are prone to fracture when they are exposed to tensile stress. Zirconia is known for its high fracture toughness.

Properties

For centuries, ceramics were used by those who had little knowledge of their structure. Today, understanding of the structure and properties of ceramics is making it possible to design and engineer new kinds of ceramics. Advanced ceramics are also used in the medicine, electrical, and aerospace industries. All ceramics are ideal aesthetics. They are alterable in time.Dental ceramics is a crystal phase and and glass phase based on the silica structure. It is not closely packed. It has both ionic and covalent characteristics. They have a glassy appearance. Silicate cements are first dental cements to use glass as its component. Dental ceramics have the ability to mimic the natural tooth in colour. Ceramics cannot undergo metal or chain realignment and they are not capable of changing their shape without fracturing unless their are heated to high temperature. They withstand chemical erosion that occurs in other materials subjected to acidic or caustic environments. Ceramics generally can

withstand very high temperatures, such as temperatures that range from 1,000 °C to 1,600 °C (1,800 °F to 3,000 °F).

They either have high melting or softening temperatures. They are brittle therefore they do not have tendency to undergo plastic deformation. They are basically hard and wear resistance. They do not conduct electricity or heat readily. They are stronger in compression than tension. They are not fully chemically Inert; they are often resistant to chemicals that would damage metals or polymers.Since they are inert they are harmless to human tissues.
Some metals used as restorative materials in dentistry may constitute a problem for some patients. These problems may reveal themselves as allergies, [11] gum staining[12,13] release of metallic ions into the gingival tissue[14] and the gingival fluid[15].Other qualities like Inertness, increased translucency, bio-compatibility, low temperature and electrical conductivity.These crowns are ideally suited to people who have minimal space within their mouth for a crown or prefer something which has a natural appearance.

Although there are some advantages of these crowns it is only fair to highlight the disadvantages as well.The disadvantage are due to inability to withstand the functional forces that are present on the oral cavity,they are brittle,they have low impact toughnesss,they appear opaque and lifeless even it is a right colour.Due to shrinkage,It is difficult to manufacture dimensionally accurate products The properties of a particular ceramic depend not just on the materials but also, on its crystalline structure. The properties of advanced ceramics have made them important for some much more extraordinary applications. The refinement needed to produce these crowns makes them more difficult to fit. They require expertise on which increases their cost.

Classification Of Ceramic System

- Glass Ceramics/ Castable Ceramics
- Sintered Ceramics
- Slip Casting Ceramics
- Hot Pressed / injection ceramics
    - machinable ceramics

Castable Ceramic

It is further classified into

- Mica based

Eg: Dicor

- Hydroxyapatite basedEg: Cerapearl
- Lithia based

Glass Ceramic

Glass ceramics were first developed by Corning Glass Works in the late 1950s. According to McLean,[16] the first works on glass ceramics were performed by Mac Culloch, but his work did not receive much attention. Further investigations by Grossman and Adair[17,18] concluded with the development of a tetra silicic mica-containing ceramic system.Glass ceramic is basically composed of a glass matrix phase and a crystal phase. Dicor was the first commercially available castable ceramic material for dental use.This has a glassy matrix and a crystalline phase. DICOR is a castable containing tetrasillic mica glass ceramic material.Composition is SiO2-45-70%,K2O-20%,MgO-13-30, 55% volume of tetrasillic mica crystals. It has increased strength,toughness, resistance to abrasion, thermal shock resistance,chemical durability,decreased translucency.

It is supplied as DICOR castable ceramic cartridges,special DICOR casting crucibles,DICOR shading porcelain.The advantages of this material are chemical and physical uniformity,marginal accuracy,uncomplicated fabrication from wax-up to casting, ceramming, and colouring, ease of adjustment, excellent aesthetics resulting from natural translucency, light absorption, light refraction, and natural colour for the crown, and its inherent resistance to bacterial plaque[19]. Some the advantages of DICOR are uniformity and purity of the material,minimal processing shrinkage, good fit, low CTE equal to that of the tooth structure,minimal abrasiveness to the tooth structure, radio opacity like dentin,moderately highly flexural strength of 152MPa.The disadvantages of the DICOR are low tensile strength,inability to be coloured internally, labour intensive,high cost. The indications of DICOR are inlays, onlays,partial tooth coverage.

Hydroxyapatite Based Castable Glass Ceramic

The example of hydroxyapatite based castable glass ceramics is Cerapearl. The complication includes CaO-45%,P2O5-15%,Mg2O-5%,SiO2-35%. The casting shrinkage of Cerapearl is

0.53%. It melts at 1460 degree C and flows like a melting glass. The cast material has an amorphous microstructure when reheated at 870 degree Celsius forms crystalline hydroxyapatite. The crystalline structure is similar to enamel. The modulus of rupture is 150MPa.The orientation and size of the crystals can account for crack deflection and blunting, which, in turn, accounts for the increase in fracture toughness over the leucite-reinforced ceramics.[20].

Sintered All Ceramic Material

Examples are Leucite- reinforced feldspathic porcelain : Optec HSP, Aluminous based porcelain : Vitadur-N TM core, Alumina based porcelain : Hi ceram, Magnesia based feldspathic porcelain, Zirconia based porcelain: Mirage II, Hydrothermal low fusing ceramics: Dueceram LFC. It is supplied as powder which can be mixed with water to form a slurry. This slurry can be built up in a layer on a refractory die to form the restoration. The powders are available in different shades and translucency. Theyare stronger because they are reinforced by crystalline phases.Clinical results have demonstrated an excellent in vivo performance at 15 years[21].

Aluminous Core Ceramics

They advocated using aluminous porcelain which is composed of aluminous oxide (alumina)crystals dispersed in a glassy matrix. The technique is devised by McLean[22]used as an opaque inner core containing 50% by weight alumina for high strength. This core was veneered by a combination of aesthetic body and enamel porcelains with 15% and 5% crystalline alumina respectively and matched thermal expansions. The resulting restorations were approximately 40% stronger than those using traditional feldspathic porcelain. Alumina is used because good mechanical properties, interfacial region between alumina and porcelain are virtually stress free. Crystals are used than powdered alumina. It has high modulus of elasticity and high fracture toughness. Advantagesincludes increase flexural strength,increased elasticity and toughness. The disadvantage of aluminous porcelain are extensive reduction, dentin preparation, binding is limited and high failure rates.

Leucite Reinforced Feldspathic Porcelain

OPTEC HSP material (leneric/Pentron, Inc.) is a feldspathic porcelain containing up to 45 vol% tetragonal leucite[23].In this type, the leucite crystals are dispersed in a glass matrix

which are nothing but potassium aluminium silicate. The leucite and glass components are fused together during baking process at 1020degree Celsius. It has high modulus of rupture and compressive strength. It does it require core unlike aluminous PJC. Examples include Optec HSP. Advantages includes : lack of metal or opaque substructure, good translucency compared to alumina crowns, moderate flexural strength, ability to be used without special laboratory equipment, and can be etched. The disadvantages includes: marginal inaccuracy caused by sintering shrinkage, has potential to fracture in posterior teeth, has increased leucite content, requires a special die material. It is used in inlays,onlays,crowns for low stress areas and veneers.

Magnesia Based Core Ceramic

Magnesia core ceramic was developed as an experimental material in 1985[24].It has high expansion core material. Advantages includes high CTE , flexural strength of magnesia core is 131 Mpa,aesthetics are superior to PFM. The disadvantages is that it can't be used in fixed partial denture.The magnesia core material can be significantly strengthened by glazing, thereby placing the surface under residual compressive stresses that have to be overcome before fracture can occur[25].

Zirconia Based Feldspathic Porcelain

Example is Mirage II which are tetragonal zirconia fibres. The advantages includes fracture toughness and thermal shock resistance. The disadvantages are translucency and fusion temperature can be adversely affected.The modulus of rupture of commercially available zirconia-reinforced feldspathic dental porcelain(Mirage II) is not significantly different from that of conventional feldspathic porcelain[26].Zirconia undergoes a crystallographic transformation from monoclinic to tetragonal at 1173°C. Partial stabilisation can be obtained by using various oxides such as CaO, MgO, Y2O3, and CeO,which allows the high-temperature tetragonal phase to be retained at room temperature. The transformation of partiallystabilised tetragonal zirconia into the stable monoclinic form can also occur under stress and is associated with a slight particle volume increase. The result of this transformation is that compressive stresses are established on the crack surface, thereby arresting its growth. This mechanism is called transformation toughening[27].

Slip Casting Ceramic

Slip-cast ceramics for dental restorations were introduced in the 1990s.crystalline phases are available, namely alumina (Al2O3), spinel (MgAl2O4) and zirconia-alumina (12 Ce-TZP-Al2O3).Ceramics are very weak and porous and must be infiltrated with glass or fully sintered before application of the veneering porcelain[28]. Materials processed by this technique tend to have fewer defects from processing, and exhibit higher toughness than the conventional feldspathic porcelain[29].The use of this technique in dentistry has been limited to one of three products[30].This limitation might be due the complicated steps, which makes achieving an accurate fit difficult[31]. Alumina-based slip-cast ceramics contain 68 vol % alumina, 27 vol % glass and 5 vol % porosity[32].The presence of large alumina crystals with a high refractive index, and a non-negligible amount of porosity, account for some degree of opacity in this all-ceramic system. Spinel-based slip-cast ceramics offer better translucency [33] similar to that of lithium disilicate heat-pressed ceramics, at the expense of mechanical properties [34].The framework contains a mixture of magnesia and alumina (MgAl2O4) to improve the translucency of thematerial [35]. Zirconia-toughened alumina slip-cast ceramics comprise 34 vol % alumina and 33 vol % of 12 mol % ceria-stabilized zirconia (12Ce-TZP).

Infiltrated Ceramics

They are otherwise known as slip cast all ceramics. Examples of infiltrated ceramics are alumina based (In ceram), In- Ceram Spinell,In- Ceram Zirconia , In- Ceram 2000. The core of In- Ceram spiral is MgAl2O2. The core of IN- Ceram alumina is 70% alumina infiltrated with 30% sodium lanthanum glass. The core of in-Ceram zirconia is 70% weight if alumina and 30% zirconia. In-Ceram spiral is used in anterior single unit inlays,onlays, crowns and veneers. In- Ceram alumina is used in anterior and posterior crowns and anterior three unit FPD’s. In-Ceram Zirconia in posterior crowns and posterior FPD’s. The advantages of the glass infiltrated ceramics systems are high flexural strength and fracture toughness,aesthetics, biocompatibility and ability to be used with conventional luring cements. The disadvantages of glass infiltrated ceramics systems are high chemical solubility,technique sensitivity, high cost,long time period for fabrication. It is contraindicated if functionally appropriate design of the restoration is not ensured, inadequate preparation, bruxism,severe discolouration of prepared teeth.

Pressable Ceramic

Examples are leucite bases :IPS Empress, Spinel based : AL Ceram. Hot pressed ceramics are becoming popular in dentistry. The restoration are waxed, invested and pressed in a manner somewhat similar to gold casting. There is better marginal adaptation with hot pressing than the high strength alumina core material. Most hot pressed material contains leucite as a major crystalline phase,dispersed in a glassy matrix. The Crystal size varies from 3 to 10 mm leucite content is 35% and glass 65%. Leucite is used as a reinforcing phase due to the tangential stressed it creates within the porcelain.This temperature is held for 20 minutes in a specially designed automatic press furnace[36].They are produced by sintering. The flexural strength of IPSEmpress material was significantly improved after additional firings[37]. The advantages includes : excellent aesthetic,translucent ceramic core,moderately high flexural strength, excellent fit, minimal shrinkage. Some of the disadvantages are potential to fracture in posterior, needs expensive equipment's, needs to use resin cement to Bond the crown micro mechanically to the tooth structure.

Machinable Ceramic

Computer Aided Design/Computer Aided Design (CAD/CAM) technology was introduced in dentistry by Duret in the early 70's[38].The best example of machinable ceramics is CAD-CAM. This uses digital information about the tooth preparation or a pattern of the restoration to provide a computer aided design (CAD) on the video monitor for inspection and modification. Thestages of fabrications are computerised surface digitalisation,computer aided design computer assisted manufacturing, computer aided aesthetics,computer aided finishing. Commercially available CAD-CAM Systems are procera, celay,sophna,Cicero,Cercon,Dux,Denticard,the Japanese system,Cercon.

Cerecincludes Cerec 1, Cerec 2, Cerec 3, Cerec 3D. Cerec 1 is a simple inlays. It has a very sharp internal angles . The Occlusal surface cannot be fabricated with CEREC 1. Cerec 2 is improved version of Cerec 1 with an addition of cylindrical grinders. The Occlusal surface can be grounded with Cerec 2. Cerec 3 is radio controlled operating system due to its design and million chamber units can be delude separately. It simplifies Occlusal and functional registration. Cerec 3D is latest version which allows 3D view of the preparation.

Celay system uses a copy milling technique to manufacture ceramic inlays and onlays.Celay system is a mechanical device based on pantographic tracing of a resin inlay or onlay

fabricated directly onto the prepared tooth or onto the master die[39].This material is similar to vita mark II Ceramic used with the Cerec 2 system[40].It has a marginal accuracy better than Cerec 2 system. Procera Allceram system involves an industrial CAD/CAM process. In LAVA system , a CAD/CAM procedure is used for fabrication of zirconia frameworks all ceramic system.

Cementation of All ceramic system

The protocol used for cementation of all-ceramic restorations can be essential for success[41].Clinicians can effectively etch silica-based all-ceramics for adhesive bonding[42].The clinical life span of such all-ceramic restorations significantly increased when this protocol is used[43].

Conclusion

The desire for beautiful teeth is a good reason to pay attention to the selection and quality of the restoration. In search for the ultimate aesthetics restorative materials, all ceramic system is the best choice among all the restorative materials.tremendous progress has been made in terms of mechanical performance, with a ten-fold increase in flexural strength and fracture toughness. Technology has developed metal-free ceramic materials which are capable of reproducing a natural appearance, whichtraditional materials have been replaced by them.The future of ceramics for dentistry is clearly open to new technologies.All-ceramic materials and systems will continue to improve.

Abstract

Products containing Probiotics had various health benefits. Traditionally Probiotics have been associated with treatment of gastrointestinal infections and disease. Various studies suggested the use ofProbiotics for oral health purposes. This study focuses on alteration in the proportion of bacterial flora in the oral cavity before and after consuming Probiotics

Keywords- *Probiotics, oral health, lactobacillus, mitis, S.Mutans*

Introduction

Probiotics can be defined as living microbes that beneficially influence the health of the host when used in adequate numbers. Probiotics are associated with gut health, and most clinically been focused on the prevention or treatment of gastrointestinal infections and diseases. Recently they have been suggested for oral health purposes too. Probiotics mouthwash can also be considered as an effective oral hygiene regimen [1]. It allows concomitant inhibition of pathogen adhesion and competitive exclusion of pathogenic microorganisms, thus allowing the production of anti-microorganism substances and modulation of the immune system. The most commonly used Probiotics bacterial strains belong to the genera Lactobacillus and Bifidobacterium.

Lactobacilli andBifidobacterium are generally regarded as secure, recently even more fermented food products have been associated for wellbeing. The species composition of both Lactobacillus and Bifidobacteriummicro biota is different between patients with periodontitis and those who are periodontally healthy. On the other hand, both Lactobacilli and Bifidobacterium are also associated with dental caries. The aim is to examine potential mechanism of Probiotics bacteria in the oral mucosa and to summarize its observed effects.

Materials and Methods

This study was carried out in nineteen healthy individuals within the age range of 18-48. The healthy volunteers were selected after the careful examination of the oral cavity for any lesions [2]. The subjects were given yakult, a Probiotics daily product made by fermenting a mixture of skimmed milk with a special strain of the bacterium Lactobacillus caseishirota, once daily for seven days. Saliva samples were collected before consuming Yakult on the first day as baseline. The collected saliva samples were inoculated into mutantssanguisagar(hi media: code m977),mitissanguis agar (hi media: code m259) and lactobacillus (hi media: code m641) which are known to be an indicator media for Streptococcus mutans, mitis and Lactobacillus bacteria [3]. The sample was diluted in 1:20 times with sterilenormal saline and 10µl of the sample is added into mutanssanguis agar, mitissanguis agar and lactobacillus which were incubated for 24 hours at 37^{o}c aerobically. After the incubation for 24hrs, the numberofbacterial colony forming unit (CFU) were counted. The colonies with white frosted glass appearance confirms Streptococcus mutans, the colonies with blue frosted glass appearance confirms Streptococcus mitis and yellow frosted glass appearance confirm Lactobacillus. After consuming Yakult for seven days, second sample was collected on the

seventhday and processed similarly. The number of mutans, mitis and Lactobacillus were counted and compared with the mutans, mitis and Lactobacillus count of samples before consuming Yakult.

Results

Table 1: Showing bacterial count before and after consuming Probiotics

	Before consuming Probiotics			**After consuming Probiotics**		
S.No	S.Mutans	Mitis	Lactobacillus	S.Mutans	Mitis	Lactobacillus
1	88	120	208	76	68	212
2	68	80	244	56	48	244
3	60	72	64	88	72	96
4	60	96	112	48	36	128
5	112	108	112	64	44	132
6	88	288	224	80	108	248
7	88	48	96	68	48	132
8	44	64	116	44	28	240
9	84	88	224	84	64	232
10	68	172	96	64	72	192
11	80	48	172	32	44	172
12	128	80	140	36	52	172
13	124	64	156	28	64	160
14	68	120	188	40	48	232
15	48	72	212	36	44	232
16	36	40	228	28	32	228
17	136	68	240	72	32	252
18	180	56	276	68	56	292
19	92	72	196	80	76	212
	1652	1756	3304	1092	1036	3808

It is evident that usage of probiotics showed significant reduction in the bacterial count of S. Mutans and Mitis and there is no reduction in the bacterial count of lactobacillus after the usage of probiotics.

Figure 1: Pie chart depicting the bacterial count

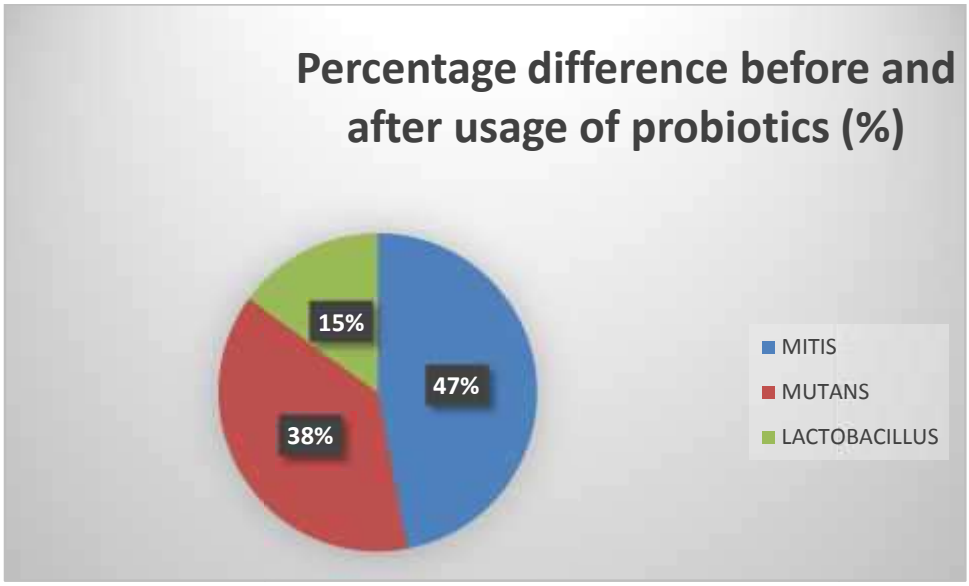

Table 2 shows percentage difference among bacterias before and after consuming probiotics

Organism	Percentage difference before and after usage of probiotics (%)
S. Mitis	**47%**
S.Mutans	**38%**
Lactobacillus	**15%**

Discussion

This study was conducted to find out the alteration in the proportion of bacterial flora in the oral cavity after consuming Probiotics [4-7]. Twenty healthy volunteers were selected after the careful examination ofthe oral cavity for any lesions. Among the twenty volunteers, one was removed for not complying with the protocol. Saliva samples were collected from the remaining nineteen volunteers. After seven days period of consuming Probiotics, the salivary

samples were subjected to microbiological examinations specific to the Streptococcus mutans, mitis and Lactobacillus load. Among the nineteen volunteers, all of them have shown a significant reduction in the mutans and mitis count. The mean average reduction of Mutans and mitis were found to be 33.89% and 41% respectively. But there was a significant increase in the Lactobacillus count with the mean average being 13.23%. Though there has been no consistent reduction in the mutans and mitis count, the mode of frequencies suggest that there is a definite influence of Yakult in reducing the bacterial pathogenic load.

Only a few studies are available on the prevalence and role and effects of Probiotics bacteria in the mouth. A study conducted among 130 volunteers at Thailand found 3790 lactobacillus strains from healthy oral cavities. Of these, five species expressed inhibitory effect against other microorganisms including oral Candida [8-10]. Also in Finland, showed an inhibitory effect on salivary counts of Streptococcus mutans and yeasts by using a combination of IgG andbifidobacteria in a short term intervention study in young adults who consumed specially manufactured cheese [11-13]. The results showed no significant difference between the groups in s. Mutans counts after the intervention, but during the post treatment period there was a significantly greater reduction in these counts in the intervention group compared with the control group [14]. More recently, Probiotics cheese was investigated in 294 self-acting elderly, aged 70-100 yr. The results showed that the Probiotics were reduced the prevalenceof oral Candida and also the risk for hypo salivation in the elderly [15]. Some studies states that the salivary pellicle influences the colonisation of bacteria on the tooth surfaces and saliva is also a potential medium for a person-to-person transmission of bacteria,including pathogenic species [16-18].

Probiotics improve colonization resistance to gut pathogens by reinforcing the mucosal barrier and restoring normal gut micro ecology after diarrhoea [18]. Probiotics have been shown to normalize an increased permeability of bacteria. Bindingis considered to be the first step of pathogenesis and binding of bacteria to the intestinal mucosa or mucus may allow the colonization [19].

Researchers state that lactic acid bacteria can produce different antimicrobial components such as organic acids, hydrogen peroxide, carbon peroxide, diacetyl, low molecular weight antimicrobial substances, bacteriocins and adhesion inhibitors. Probiotics can also activate and modulate the immune system [8], and they have shown to reinforce gut defence by immune exclusion, immune elimination and immune regulation [9]. Nevertheless, since

mouth represents the first part of the gastrointestinal tract, there is every reason to believe that the fermented milk containing Lactobacillus caseishirota has a beneficial role in the mouth [19,20].

Conclusion

Probiotics containing dairy products such as Yakult, curd, cheese are consumed on daily basis. These products reduce the pathogenic bacteria load in the oral cavity and also known to enhance the digestive system. This is known to bring direct benefit in reducing dental caries, dental plaque, xerostomia, halitosis etc. They are probably going to play an important role in dealing with the problems arising from overuse of antibiotics and antimicrobial resistance. Probiotics are nevertheless, a new and interesting field of research in oral microbiology and oral medicine. The concept casts new light on the connections between diet and health, including oral health.

Alteration in the Taste Function after the Extraction of an Impacted Mandibular Third Molar- A Review.

Deepti Anna John[1], Jaiganesh Ramamurthy[2]

Graduate Student[1], Reader[2], Department of Periodontics,

Saveetha Dental College, Saveetha Institute of Technical and Medical Sciences, Saveetha University, Chennai, India

Abstract

The third molar extraction is one of the most common procedures done in Oral and maxillofacial surgery. The common solution to an impacted third molar is to remove the tooth by surgical extraction. The third molar extraction is a frequently done dental procedure. The extraction of the third molar requires accurate planning and skill. The mandibular third molar lies closely to the branches of the mandibular nerve such as the lingual, inferior alveolar and buccal nerves and the chorda tympani branch of the facial nerve. The surgery endangers the Lingual nerve and the Inferior alveolar nerve, and if the lingual nerve gets damaged there are alterations in the taste function. The review is done to get a better understanding on how the taste function gets affected after the removal of a third molar and if it is a common occurrence and to determine the incidence and the occurrence of change in the taste function after the third molar is removed.

Key Words*: Third molar, taste change, anaesthesia, extraction, impaction*

Introduction

Impaction, according to Mead in 1945 is defined as a tooth that is prevented from erupting because of lack of space, malposition and other impediments. It was also defined by Peterson as those teeth that fails to erupt into the dental arch within the expected time. According to Farman in 2004, impacted teeth are those teeth that prevented from eruption due to a physical barrier within the path of eruption (1). The third molar is one of the three molars per quadrant of the human dentition. The third molar is commonly known as the wisdom tooth as it erupts between the ages of 17 and 25. The most common tooth to get impacted is the Third molar which occurs in about 73% (2) and hence affects the other teeth or causes problems in the oral cavityranging from infection, inflammatory to cystic lesions necessitating their surgical removal.

The common solution to an impacted third molar is to remove the tooth by surgical extraction. The third molar extraction is a frequently done dental procedure. In 1977, it was stated that 2.25 million third molars are removed annually but this procedure is of a difficult degree and can lead to multiple complications such as the iatrogenic damage to the trigeminal nerve.

Reason of Mandibular Third Molar Impaction

Many theories have been proposed for the impaction of the mandibular third molar such as insufficient retromolar space, the mandibular ramus growth depends on resorption at its anterior surface and deposition at its posterior surface, but due to defect in this process, the mandibular third molars don’t get enough space to erupt (3). The eruption also depends on the favourable path of eruption, like if the tooth bud is angulated towards the medial side during the early stages of calcification and root development the path of eruption will be deemed unfavourable (4). Angulation of the mandible can also affect the eruption pathway. Yamaoka et al found that the root angulation is related to impaction as angulated roots were more common in impacted mandibular third molars as compared to erupted mandibular third molars (5). A lack of sufficient eruption force for third molars and decreased mesial movement of the modern human dentition due to lack of interproximal attrition (6).

Impaction can be of different types such as mesio angular, vertical, distoangular and horizontal Impaction. Mesioangular is the most common type of Impaction seen, studies say that there is a strong genetic influence that plays a role in molar Impaction (7).

Relation of the Mandibular Third Molar with the Mandibular Nerve

The Trigeminal nerve is the Vth cranial nerve which is divided into three branches, the ophthalmic, maxillary and the mandibular nerves. The trigeminal nerve (V) is responsible for the general sensory innervation of the tongue.

The mandibular nerves are divided into many branches such as the inferior alveolar, lingual, buccal nerves. The mandibular third molar lies closely to the branches of the mandibular nerve such as the lingual, inferior alveolar and buccal nerves and the chorda tympani branch of the facial nerve.

Neurosensory disturbances related to the inferior alveolar nerve due to the close anatomic relationship between the roots of mandibular third molars and the inferior alveolar canalis one of the most grave complications of such a procedure. The prevalence of inferior alveolar nerve paraesthesia following third molar surgery ranges approximately from 0.4 to 8.4 % according to different studies(8).So during the surgical extraction there are chances that these nerves could get damaged. The nerve damage causes sensory disturbances such as loss of gustatory function (dysgeusia and aguesia) (9). The nerve damage may be due to the anaesthetic injection given that causes haemorrhage with the epineurium or the neurotoxic effect of the anaesthetic.

As the mandibular third molar is located at the distal end of the body of the mandible where the ramus is thin. This is the region of weakness and a fracture can easily occur if a greater amount force is applied during impacted wisdom tooth elevation without preliminary and adequate removing of surrounding bone. The buccal alveolar bone is thicker than the lingual. The external oblique ridge forms the buttress that reinforced the buccal plate. The lingual nerve is situated close to the cortical plate and there is an increased risk of lingual nerve. In a few cases third molar roots may penetrate into mandibular canal or close relationship of the canal with the roots can evoke inferior alveolar nerve damage during the

surgery (10).The taste sensation is responsible by the three cranial nerves: facial nerve (VII), glossopharyngeal (IX) and vagus(X).

The close anatomic proximity of the mandibular third molar to the chorda tympani or lingual nerve or both during surgical procedures could lead to gustatory deficit (11). In the anterior 2/3rd of the tongue, the taste impulses are initiated and are transmitted to the medulla oblongata through the taste fibres that arise from the lingual nerve. Then the fibres leave the nerve and form a part of the chorda tympani. Some of the gustatory fibres arise on the tongue also might reach the brain stem through the mandibular nerve. So, the presence of this pathway may be the reason of unilateral loss of taste (12). Hence, the aim of the review is to understand whether the removal of an impacted mandibular third molar can affect the gustatory function.

Extraction of Mandibular Third Molar and Its Significance to Gustatory Function

According to C.D Lehman (1995), the tongue is divided into two halves which are innervated by two different nerves- the anterior two thirds is innervated by the chorda tympani branch of the facial nerve and the posterior one third is innervated by the glossopharyngeal nerve. Anaesthesia of the chorda tympani nerve given during a dental procedure increases the taste sensation of the areas innervated by the glossopharyngeal nerve. This follows the principle of Halpern and Nelson's release of inhibition hypothesis (13). Yanagisawa et al (1998), reported that if the chorda tympani nerve was anaesthetized the taste of quinine was intensified and the taste of NaCl was diminished. In 40% of his subjects, tastes occurred in the absence of stimulation (taste phantoms); the phantoms may occur due to the anaesthesia that releases inhibition normally occurring between the central projections areas of different taste nerves (14).

Shafer DM et al (1999) observed the taste function of 17 patients before the third molar surgery and at 1 month and 6 months after the surgery, the taste intensity in certain areas of the tongue had diminished and the patients with the severely impacted molar gave the lowest values. Their study concluded that gustatory deficits occur after the third molar extraction and last as long as 6 months and also depends on the depth of the impaction (15). DGulicher et al (2001), their study involved the removal of 1106 impacted mandibular molars

from 687 patients, the common sensation was examined to assess sensory deficit. 3.6% of the operated sides showed impairment of labial sensation and 2.1% of lingual sensation. Persisting Sensory diminution was seen in the inferior alveolar nerve and lingual nerve. The factors concerned according to the study were general anaesthesia and the individual operator (16).

Anwar B.Bataineh (2001), the study was conducted with 741 patients whose 741 mandibular third molars were removed under local anaesthesia, the results showed that 19 patients had post-operative lingual nerve paraesthesia and they belonged in the under 20-year old age group (17).Steven B. Graff-Radford et al (2003) examined a case of a 24 year old woman, who underwent local anaesthetic blocks and removal of upper and lower molars by her dentist but started feeling numbness and tingling of the left side of her tongue and the floor of her mouth, she also felt a change in the taste of meat. On examination, it was seen that the lingual nerve was damaged (18).U.K.Akal et al (2004), the study was done to determine the drastic taste changes after all the four third molars were removed.27 patients were subjected to two gustatory test but the final result showed no significant changes in the gustatory function after the third molar surgery (19).Linda M.Bartoshuk et al(2005),reported that taste phantoms are localized to contra lateral rear of the tongue when anaesthesia is given to the chorda tympani (20).Ana Claudia Amorim Gomes et al (2005), their study had a total of fifty five patients referred for bilateral mandibular third molar removal, lingual flap retraction done during the surgical procedure damaged the lingual nerve (21).WaseemJerjes et al (2010), their study reported that permanent sensory dysfunction is depends on the surgical skills of the operator, type of impaction, radiographic proximity of the tooth to the inferior alveolar nerve (22).Lourdes Ridaura- Ruiz et al (2012),their studied reported that lower third molar removal under local anaesthesia may cause light lingual sensibility impairment, but this in most cases remains undetected to the patients. The injuries if present are seen for only a week after the surgery. The taste remains unaffected (12). W. P Smith (2013), observed 1000 patients and reported a preoperative warning that temporary neurosensory deficit is highest when the root apices are intimate with the inferior alveolar nerve and permanent damage is done when the nerve is intimate with the canal (23).

Investigation Done to Determine the Close Proximity of the Mandibular Nerve to the Impacted Third Molar

Pre-operative radiographic assessment of the proximity of the mandibular nerve to the impacted molar is a vital part and essential requirement before surgical removal of impacted mandibular third molars. Orthopantomograms are commonly used for the assessment.
Radiographs should be carefully studied and the following features should be noted prior to the extraction procedure.

a. Radiographic distance between the impacted third molar and the inferior alveolar canal. The mean distance is said to be 1.5011mm
b. Risk predictor signs –
    - Darkening of the root- indicates the impingement of root on the canal
    - Interruption of the white line –discontinuity in the opaque border that indicates the border of the inferior alveolar canal.
    - Diversion of the canal
    - Narrowing of the root
    - Dark and bifid root – indicates impingement by the canal

Presence of two or more of the risk factors seen in the radiograph indicates the close proximity of the nerve to the tooth and increases the risk of damage to the nerve (24)
Therefore in these cases, the oral surgeon should do the extraction using copious amounts of irrigation of the socket and direct visualisation of the inferior alveolar canal, to ensure least amount of complications.

Panoramic radiographs are said to be gold standard diagnostic tools in the preoperative assessment of mandibular third molars and their relationship with the inferior alveolar canal (25) and have been known as the radiographs of choice. As a protocol, the Finnish Student Health Service in Helsinki proposes use of advanced imaging techniques only when panoramic radiographs suggest a close relationship between the impacted mandibular third molar and the inferior alveolar canal.

Conclusion

The literary search was done to understand the connection of the mandibular third molar with the taste function. From the articles, it's concluded that the removal of the mandibular third molar does not cause drastic changes to the gustatory function or no change at all in most cases, but if the nerves get damaged there are chances for neurosensory dysfunction to be present but it may last for at least 6 months. It is possible that if the taste loss persists beyond 6 months together with other factors that affect taste and accumulate over a lifetime, contributes to the decrease in taste function seen with age. The major factors that are responsible for the damage of the nerves closely related to the mandibular third molar are application of anaesthesia and the skill of the operator.

Abstract

The term amyloid describes the deposition in the extracellular space of certain proteins in a highly characteristic, insoluble fibrillar form. . Amyloidosis can occur any single organ or associated with other organs . It is formed in in the form of a tumor like lesion or an infiltrative process. In the proper clinical setting, that is, in a patient with chronic inflammatory disease and especially in a patient with multiple myeloma, amyloidosis should be considered as a possible cause of worsening or new symptoms or imaging findings. Occasionally, the radiologic findings may precede the clinical findings, thus providing the radiologist with the opportunity to contribute to the patient's care. However, to make a difference in patient care, the radiologist must be familiar with the diverse imaging findings of amyloidosis as well as the patient's clinical history, which could raise the suspicion of amyloidosis.Amyloidosis describes the various clinical syndromes that occur as a result of damage by amyloid deposits in tissues and organs throughout the body. The clinical significance of amyloid varies enormously, ranging from incidental asymptomatic deposits to localized disease through to rapidly fatal systemic forms that can affect multiple vital organs. Currently available therapy is focused on reducing the supply of the respective amyloid fibril precursor protein and supportive medical care, which together have greatly improved survival Quality of life and prognosis of some forms of hereditary systemic amyloidosis can be improved by liver and other organ transplants. Various new therapies, ranging from silencing RNA, protein stabilizers to monoclonal antibodies, aimed at inhibiting fibril precursor supply, fibril formation or the persistence of amyloid deposits, are in development; some are already in clinical phase.

Key Words*: amyloidosis, dialysis ,lysosome, systemic amyloidosis, nephrotic syndrome.*

Introduction

Amyloidosis is a disorder of protein folding in which various proteins are able to autoaggregate in a highly abnormal fibrillar conformation. Amyloid fibrils accumulate in the extracellular space, and the deposits progressively disrupt the structure and function of tissues and organs throughout the body.[1] Amyloidosis is a rare condition; approximately 500 new cases are referred to the UK National Amyloidosis Centre each year and it has been estimated that 0.5 – 1.0 deaths per 1000 in the UK are due to the most prevalent AL type. Amyloid type is classified according to the fibril protein, and some 25 different proteins are known to form amyloid fibrils in vivo.[2] Deposition of amyloid is diverse, ranging from localized deposits that can be incidental to progressive systemic disease which can be rapidly fatal. Amyloidosis can be inherited or acquired, and its anatomical distribution and natural history vary greatly between, and sometimes within, fibril types. Precise pathological diagnosis and comprehensive clinical evaluation are imperative for appropriate clinical management.The systemic amyloidoses are a group of complex diseases caused by tissue deposition of misfolded proteins that results in progressive organ damage. The most common type, immunoglobulin light chain amyloidosis (AL), is caused by clonal plasma cells that produce misfolded light chains.[3] The purpose of this review is to provide up-to-date information on diagnosis and treatment options for AL amyloidosis. Early, accurate diagnosis is the key to effective therapy, and unequivocal identification of the amyloidogenic protein may require advanced technologies and expertise. Prognosis is dominated by the extent of cardiac involvement, and cardiac staging directs the choice of therapy. Treatment for AL amyloidosis is highly individualized, determined on the basis of age, organ dysfunction, and regimen toxicities, and should be guided by biomarkers of hematologic and cardiac response. Alkylator-based chemotherapy is effective in almost two thirds of patients. Novel agents are also active, and trials are ongoing to establish their optimal use. Treatment algorithms will continue to be refined through controlled trials. Advances in basic research have led to the identification of new drug targets and therapeutic approaches, which will be integrated with chemotherapy in the future[4].

Fibril Formation and Amyloid Proteins

Amyloid fibrillogenesis remains poorly understood. Experiments have shown in vitro that nearly any polypeptide chain can be driven towards misfolding and aggregation given specific conditions,(4) but relatively few proteins are amyloidogenic in vivo. The

polypeptides involved in amyloidosis are structurally diverse in their normal conformation and may be notably rich in b-sheet, a-helix or b-helix.(5) During amyloidogenesis, multimeric proteins dissociate to their monomeric components, and may further be enzymatically cleaved before or during their conversion into amyloid fibrils.(6,7) There are essentially three circumstances in which amyloid deposition occurs. The first is when there is sustained abnormally high abundance of certain proteins that are normally present at low levels, such as serum amyloid A protein (SAA) in chronic inflammation, underlying susceptibility to AA amyloidosis. The second is when there is normal abundance of a normal, but to some extent inherently amyloidogenic protein over a very prolonged period, such as transthyretin in senile amyloidosis (ATTR). The third situation is the presence of an abnormal protein with markedly amyloidogenic structure, such as certain monoclonal immunoglobulin light chains in AL amyloidosis and genetic variants of transthyretin, apolipoprotein AI and fibrinogen Aa chain, etc. in hereditary amyloidosis. Despite the heterogeneity of the various precursor proteins, the morphological structure and histochemical properties of all amyloid fibrils are remarkably similar. The core structure comprises antiparallel b-strands of polypeptide chains lying perpendicular to the long axis of the fibril.(8) On electron microscopy, amyloid fibrils are characteristically straight, non-branching and 7 –10 nm in diameter.(9) Amyloid deposits also contain the non-fibrillar normal plasma protein, serum amyloid P component (SAP),(10) which is bound in a reversible calciumdependent manner to a ligand present on all amyloid fibrils.

Diagnosis of Amyloidosis and Imaging

Amyloidosis is extremely heterogeneous and clinical presentation varies widely depending on which organs are involved. Diagnosis is often made late in the course of the disease, and frequently as an unexpected histological finding when a failing organ is biopsied. Congo red staining of tissue yielding the characteristic apple green birefringence under crossed polarized light remains the gold standard for confirming the presence of amyloid, this pathognomonic optical effect being produced by alignment of the dye molecules along the fibrils. The protein composition of the amyloid fibril, i.e. the type of amyloidosis, must then be ascertained, and this is most accessibly achieved by immunohistochemistry(11-13). However, immunohistochemical staining of amyloid deposits can be confounded by many factors including background staining and loss of antigenic determinants in the fibrillar conformation, especially in the common AL type. Proteomic analyses comprising mass spectrometry on amyloid material cut out from tissue sections by laser capture microscopy

has lately proved to be effective in a large proportion of cases.(14-16) Whereas target organ biopsies are usually diagnostic, amyloid deposition can be patchy and random 'screening' biopsies, e.g. of the gut, are negative in a considerable proportion of cases. Various imaging techniques can make an important contribution to the diagnosis and evaluation of organ involvement in amyloidosis. Of these, only radiolabelled SAP scintigraphy is specific.(17) The normal plasma protein SAP binds reversibly to all types of amyloid fibril, and is present in all amyloid deposits. Intravenous injection of 123I-SAP rapidly equilibrates between the relatively small quantity of endogenous SAP within the circulation and SAP present within the extravascular amyloid deposits. SAP scintigraphy thus enables visceral amyloid to be imaged for diagnostic purposes, and since the method is quantitative, it enables the deposits to be monitored serially. SAP scintigraphy has characterized the dynamic nature of amyloid, and has shown that frequently the deposits gradually regress when the supply of the respective precursor protein is reduced. Limitations include restricted availability, and the inability to image amyloid deposits in small or moving structures such as nerves and the heart. Fortunately, several cardiac imaging modalities yield characteristic and clinically important information regarding myocardial involvement. Echocardiography has long been used to demonstrate thickening of the ventricular walls and valves, and to evaluate the predominant diastolic restrictive abnormality that occurs in cardiac amyloidosis . Cardiac involvement has been defined as a mean left ventricular wall thickness of .12 mm in the absence of hypertension or other causes of left ventricular hypertrophy,(18) although poor echocardiographic windows and interoperator variability are significant limitations. Cardiac magnetic resonance (CMR) imaging has lately fallen into widespread clinical practice, demonstrating very characteristic late gadolinium enhancement in subendocardium or more diffusely.(19,20) Although the role of CMR for monitoring progression or regression of amyloid has yet to be defined, the use of equilibrium CMR may prove to be a useful tool in quantification of amyloid, a technique which has been validated in fibrosis.(21) The biomarkers N-terminal pro brain natriuretic peptide (NT-proBNP) and cardiac troponins are also now widely used to provide information on cardiac involvement, prognosis and response to chemotherapy in AL amyloidosis.(22) Since 5 –10% of systemic amyloidosis is hereditary, genetic testing is often required, but the results must be interpreted in light of other findings, notably immunohistochemical or proteomic typing of the amyloid.(23-26) The clinical phenotype associated with particular mutations may be a classification of systemic amyloidosis by precursor protein Type Fibril protein precursor Clinical syndrome Acquired forms of systemic amyloidosis AA Serum amyloid A protein Reactive systemic amyloidosis

Cardiac involvement has been defined as a mean left ventricular wall thickness of .12 mm in the absence of hypertension or other causes of left ventricular hypertrophy,(18) although poor echocardiographic windows and interoperator variability are significant limitations. Cardiac magnetic resonance (CMR) imaging has lately fallen into widespread clinical practice, demonstrating very characteristic late gadolinium enhancement in subendocardium or more diffusely.(19,20) Although the role of CMR for monitoring progression or regression of amyloid has yet to be defined, the use of equilibrium CMR may prove to be a useful tool in quantification of amyloid, a technique which has been validated in fibrosis.(21) The biomarkers N-terminal pro brain natriuretic peptide (NT-proBNP) and cardiac troponins are also now widely used to provide information on cardiac involvement, prognosis and response to chemotherapy in AL amyloidosis.(22) Since 5 –10% of systemic amyloidosis is hereditary, genetic testing is often required, but the results must be interpreted in light of other findings, notably immunohistochemical or proteomic typing of the amyloid.(23-26).The clinical

phenotype associated with particular mutations may vary, even within a given kindred, and since penetrance is variable, patients with AL amyloidosis can occasionally have an incidental mutation.(27,28) Conversely, some patients with hereditary amyloidosis have a potentially misleading but coincidental monoclonal gammopathy.(28,29)Biochemical analyses are an integral part of the diagnostic process. A plasma cell dyscrasia can be identified in approximately 94% of patients with AL amyloidosis.(30) Monoclonal proteins can be detected by serum and urine electrophoresis and immunofixation, although the fully quantitative high sensitivity serum free light chain (FLC) assay is usually best for serially monitoring progress and response to chemotherapy in AL amyloidosis.(31) Bone marrow examination and skeletal X-ray surveys are required to exclude frank multiple myeloma. It is, however, important to note that incidence of monoclonal gammopathy of undetermined significance occurs in at least 3% among people over 50 years, and demonstration of a plasma cell dyscrasia therefore does not by itself confirm amyloidosis is of AL type. Diagnosis of amyloidosis is thus a multidisciplinary process, encompassing the clinical picture, various imaging modalities, histology, immunohistochemistry, proteomics, haematological and biochemical investigations and genetic analyses.

Localized Amyloid

Localized amyloid deposition results from the local production of fibril precursor proteins.(32)Most clinically significant deposits are AL type, associated with foci of low-grade monoclonal B-cells which secrete monoclonal immunoglobulin light chains in the immediate vicinity.(33,34) The most frequent sites of deposition are the respiratory tract, the urogenital tract, the skin and orbits, but all are rare.(35) There are case reports of amyloid affecting almost any site ranging from intracranial amyloidomas,(36)amyloidoma affecting the larynx and oropharynx(37) to localized amyloid of the vagina.(38) Local resection of the ‘amyloidoma’ can sometimes be curative,(39) but amyloid deposits can recur within the same site or elsewhere in the same tissue. Amyloid deposits that appear to be localized can sometimes be a manifestation of systemic disease. It is therefore important to fully investigate patients in order to exclude systemic amyloidosis.(40) Once established that the amyloid deposit is localized, the management is dictated by the area involved and the degree of symptoms. Due to the extremely rare nature of the disease, management strategies have been somewhat experimental, ranging from radiotherapy,(41) to carbon dioxide laser ablation.(42) If the lesions are not causing symptoms, then clinical surveillance may well be all that is needed. Localized masses of amyloid can be found at insulin injection sites when repeated

administration to the same area has occurred over many years.(43) This form of amyloid stains with antibodies to insulin and has been termed iatrogenic A-Ins type amyloid.

Systemic Amyloidosis

Four major acquired forms of systemic amyloidosis have so far been identified. These are systemic light chain amyloidosis (AL); systemic amyloid A amyloidosis (AA); dialysis-related amyloidosis (DRA); and senile systemic amyloidosis (ATTRwt).

Systemic AL Amyloidosis

AL amyloidosis is the commonest form of amyloid and is thought to be the cause of death in 1/1500 people in the UK. The fibrils are formed of fragments of monoclonal immunoglobulin light chains consisting of all or part of the variable domain (VL).(44) AL amyloidosis is a rare complication of monoclonal gammopathies and can occur in association with any form of monoclonal B-cell dyscrasia.30 The plasma cell proliferation fraction is usually similar to that of monoclonal gammopathy of undetermined signifi- cance (MGUS).(45) Approximately 15% of patients have multiple myeloma and within this group symptomatic myeloma is unusual.(30) Median age at presentation is 50– 60 years and both sexes are equally affected.30 Presentation is extremely variable as almost any organ can be affected except the brain. It is usually diagnosed incidentally on a biopsy. Clinical suspicion of amyloidosis should be raised in any patient with unexplained nephropathy, cardiac failure, peripheral or autonomic failure, hepatomegaly or splenomegaly or any unexplained multisystem disease. Approximately 50% of cases involve the kidneys presenting with proteinuria and frequently nephrotic syndrome. Kidney remains the commonest tissue from which the disease is identified. Patients with AL amyloidosis can develop acquired factor X deficiency, underlying some reluctance to perform biopsies in patients with AL amyloidosis. Factor X assays are important in patients with abnormal clotting, and replacement with fresh frozen plasma prior to biopsy in those who are deficient is recommended.(46) However, overall, the incidence of bleeding complications following renal biopsy in 138 patients with cast nephropathy or amyloid was no different from those without.(47) Cardiac involvement causing heart failure at presentation occurs in 15–30% of cases. Symptoms of cardiac involvement are those of congestive cardiac failure most commonly with progressive breathlessness .The prognosis in untreated AL amyloidosis is very poor with a median survival of only 6 –15 months and a 10-year survival rate of ,5%.30 The prognosis, however, is somewhat dependent on the organs involved with cardiac and autonomic nerve

involvement conferring a particularly poor prognosis. The current management of AL amyloidosis is to aim to suppress the production of the underlying B-cell clone with chemotherapy and in turn halt the production of amyloidotic light chains. Evidence suggests that remission of the underlying clonal disease is associated with preservation of organ function and in some cases remission of amyloid deposits. Early identification and treatment is associated with improved survival.All current therapies in AL amyloidosis have been derived from experience in multiple myeloma, but adverse effects are far more frequent and severe in AL due to the multisystem nature of the disease. It is vitally important that an individual assessment is made for each patient and treatment regimens are tailored accordingly. A variety of therapies have been employed ranging from high-dose autologous stem cell transplantation to oral-based regimens.

Systemic AA Amyloidosis

AA amyloidosis is a rare complication of chronic inflammatory conditions. The fibrils in AA amyloidosis are derived from the circulating acute phase reactant SAA, which is produced by hepatocytes under the transcriptional regulation of pro-inflammatory cytokines.(60) The median plasma concentration of SAA in health is ,3 mg/L, but it can increase more than a thousand-fold during the acute phase response. Longstanding elevation of SAA is a prerequisite to development of AA amyloidosis but it is rare and its incidence varies throughout the world, and for example seems less common in the USA compared with central Europe and Scandinavia.(61-63) The commonest predisposing conditions in the Western world are the chronic inflammatory arthropathies, which account for over 50% of cases. In the developing world, reported cases are mainly associated with underlying infection. Patients with hereditary periodic fever syndromes are especially susceptible, perhaps due to the lifelong nature of these inflammatory diseases, and this risk is substantially increased when there is a family history of AA amyloidosis(64). Other rare causes include Castleman's disease, vasculitis and neoplasias such as lymphoma and mesothelioma. Biopsy and postmortem studies have suggested a prevalence of up to 3 – 6% in rheumatoid arthritis (RA), and 11– 13% in familial Mediterranean fever despite availability of colchicine treatment for the latter.The factors that govern susceptibility to AA amyloidosis in the face of a high SAA concentration are yet to be determined. Polymorphisms in the gene encoding for SAA1 isotype may contribute in part.AA amyloidosis predominantly affects the kidneys, with more than 95% of patients presenting with proteinuria, and around 10% of patients having already reached end-stage renal failure at diagnosis(50-54). Splenic involvement is evident on SAP

scintigraphy almost without exception, and deposits commonly occur in the adrenal gland, liver and GI tract, although usually without associated organ dysfunction. Cardiac and neuropathic involvements are extremely rare.(62) Patients with persistent inflammation frequently develop progressive renal dysfunction and end-stage renal failure within 5– 10 years. Almost 60% have nephrotic syndrome at presentation, which confers a high risk of infection. Acute kidney injury is common and is often non-reversible, emphasizing the need for great care with regard to hypoperfusion, nephrotoxic drugs and surgery. Patient outcome has gradually improved, with a recently reported median survival of 133 months.(62-63) Outcome is poorer in association with older age, lower serum albumin and end-stage renal failure at presentation. Serum SAA concentration has a powerful and modifiable influence on outcome; complete suppression of inflammation in terms of SAA concentration persistently ,5 mg/L is frequently associated with regression of amyloid and preservation of renal function. Treatment will differ according to the nature of the underlying chronic inflammatory disorder, and there has lately been much progress with biological therapies for rheumatoid arthritis, etc., but progressive renal dysfunction remains common and end-stage renal failure occurs in up to a third of patients. Median survival on dialysis is in the order of 4– 5 years, which is similar to that among age-matched non-diabetic patients; renal transplantation has been performed in selected cases with reportedly excellent outcomes.

Dialysis-related Amyloidosis

Dialysis related amyloidosis is a complication of long-term dialysis following endstage renal failure. The underlying fibril is due to b2- -microglobulin (b2M). b2M is the light chain component of the major histocompatibility complex (MHC) class 1 molecule. It is synthesized in all cells that express MHC class 1 molecules. b2M is cleared from the body by the kidney. It is freely filtered by the glomerulus and reabsorbed by the proximal tubular cells. When patients develop end-stage renal failure, b2M accumulates and the circulating concentration rises from normal levels (1 – 2 mg/L) to 50 –70 mg/L(59).

Senile AA Systemic Amyloidosis

It is a disease of the elderly and usually affects men; the fibril is composed of normal wild-type transthyretin. Transthyretin is a transport protein that circulates in a tetrameric form. More than 95% of transthyretin is produced in the liver, with the remainder in the choroid plexus and in the retina.The most common transthyretin mutation involves the substitution of methionine for valine at position 30 (ATTRV30M). This usually presents with sensori-motor

peripheral neuropathy and, unlike most other mutations, cardiac involvement is rare. The disease typically develops by age 30– 40 years in the Portuguese focus, but about 20 years later in the Swedish one.(57) The most common aetiology of FAP in the UK and Ireland is the T60A variant. This usually presents after the age of 50 and often with autonomic symptoms, but cardiac amyloid is virtually always present at diagnosis. Three to four percent of black individuals have the V122I transthyretin variant, which is associated with a predominantly cardiac phenotype that is clinically indistinguishable from senile cardiac amyloidosis; it usually presents after age 60 and is not associated with neuropathy.(60)

TheHereditary Systemic Amyloidosis

Hereditary amyloidosis is a group of diseases due to mutations in different specific proteins. Hereditary systemic amyloidosis can be divided into neuropathic and non-neuropathic forms. The former comprise familial amyloid polyneuropathy (FAP), usually caused by mutations in the transthyretin gene (ATTR) and gelsolin amyloidosis (AGel)(61). Non-neuropathic forms include fibrinogen Aa-chain amyloidosis (AFib), apolipoprotein AI amyloidosis (AApoAI), apolipoprotein AII amyloidosis (A ApoAII) and lysozyme amyloidosis (ALys).

Lysozyme Amyloidosis

Lysozyme amyloidosis was first described by Pepys et al. in 1993. Lysozyme is a bacteriolytic enzyme found in high concentrations in the liver, articular surfaces, saliva and tears. It is highly expressed in granuloctes, monocytes and bone marrow precursor cells. To date, seven amyloidogenic mutations have been found: Ile56Thr, Phe57Ile, Trp64Arg, Asp67His, Trp112Arg, Tyr54Asn and Asp67Gly. Clinical presentation is with very slowly progressive renal failure, usually in the third and fourth decades. Involvement of the liver, lymph nodes, GI tract and spleen also occurs. Sicca syndrome due to salivary amyloid deposition is frequent in patients with Try64Arg and Asp67His variants, and lung and thyroid deposits have been reported in patients with Ile56Thr(54).

Conclusion

Amyloidosis is a diverse group of multisystem diseases in which much progress has been made in recent years. There have been major developments in diagnosis, ranging from scintigraphic imaging methods and cardiac MRI, to improved molecular characterization of amyloid deposits through mass spectrometry and genetic sequencing. Clinical outcomes have improved through advances in chemotherapy, biologic anti-inflammatory agents and organ

transplantation in AL, AA and hereditary amyloidosis, respectively. Assessment of underlying diseases and amyloidotic organ function with biochemical markers such as the serum free light chain assay, SAA measurements and the cardiac biomarker NT-proBNP, have greatly improved the monitoring of patients. A new era of clinical trials to test the first drugs specifically designed to prevent or remove amyloid deposits is upon us, promising a brighter future for patients with these very serious diseases.

Abstract

Iron is crucial for human biologic functions, including respiration, energy production, DNA synthesis, and cell proliferation. The human body has evolved to conserve iron inways, including the recycling of iron after the breakdown of red cells and the retention of iron. Since excess levels of iron can be toxic, absorption of iron is limited to 1 to 2 mg daily, and most of the iron needed daily, about 25 mg is provided through recycling by macrophages that phagocytose senescent erythrocytes. The two mechanisms are controlled by the hormone hepcidin, which maintains total iron content within normal ranges, avoiding both iron deficiency and excess. Iron deficiency refers to the reduction of iron stores that precedes iron deficiency anemia or persists without progression. Iron-deficiency anemia is a more severe condition in which low levels of iron are associated with anemia and the presence of microcytic hypochromic red cells. This review considers iron deficiency and its anemia in light of advances in the understanding of systemic iron homeostasis and examines causes, pathophysiological featuresand treatment options in adolescents.

KeyWords: *Anaemia, Iron deficiency, Adolescence, Dietary requirements, Treatment.*

Introduction

World Health Organization defines adolescence as a period of human development characterized by the transition between their childhood and adult life with somatic, psychological and social changes. Teenagers present a higher demanding of nutrients reasoned by the enlargement of total blood volume and iron pool, in consequence of an increase of thin body mass quantity. In addition, girls have a mineral loss due to the

menstrual cycle. Thus, iron deficiency is nearly almost twice higher during puberty(1). A 30% prevalence of iron deficiency anaemia, at a minimum, has been noted among children, adolescents, and women in non-industrialized countries(2). Iron deficiency anaemia is considered to be one of the main public health issues throughout the world. Insufficient dietary intake and absorption of iron is the top responsible for malnutrition. Even mildly, it is harmful to the health since it is associated to damages in productive capability, cognitive development and immune competence of individuals(3). Adolescent pregnancies are also at increased risk of severe anaemia, preterm deliveries, still births, and neonatal deaths, due to competition between nutritional requirements of the developing foetus and the mother's requirement for continuing growth(4). Knowledge of the degree and main risk factors of anaemia in adolescence is of public health importance as this is a window of opportunity for school based interventions to improve adolescent health(5).

ImportanceofIron

Iron is a significant element for most life on Earth, including human beings. Iron is needed forcomplex processes that continuously take place on a molecular level, which are indispensable to human life. Iron is an essential component of haemoglobin, myoglobin, and many enzymes in cellular metabolism and DNA replication and repair. It also plays a crucial role in the development of the central neurological system(6),(7), autoimmune system (8),(9)endocrine system- thyroid regulation (10),(11)and cardiovascular system (12). In the development of the brain, iron accounted for the myelination of white matter and the development and functioning of the different neurotransmitter systems, including the dopamine, nor epinephrine, and serotonin systems (13),(14),(15).

IronDistribution in HumanBody

The human body contains approximately 3–5 g of iron, distributed as illustrated in Fig. 1. The majority of body iron (~60–70%) is utilized within haemoglobin in circulating red blood cells. Approximately 20–30% of body iron is stored in hepatocytes and in reticuloendothelial macrophages in the liver. The remaining body iron is primarily localized in myoglobin, cytochromes, and iron containing enzymes. A healthy individual absorbs daily 1–2 mg of iron from the diet, which compensates nonspecific iron losses by cell desquamation in the skin and the intestine. In addition, menstruating women physiologically lose iron from the

blood. Erythropoiesis requires approximately 30 mg iron/day, which is mainly provided by the recycling of iron via reticuloendothelial macrophages(16),(17),(18),(19),(20).

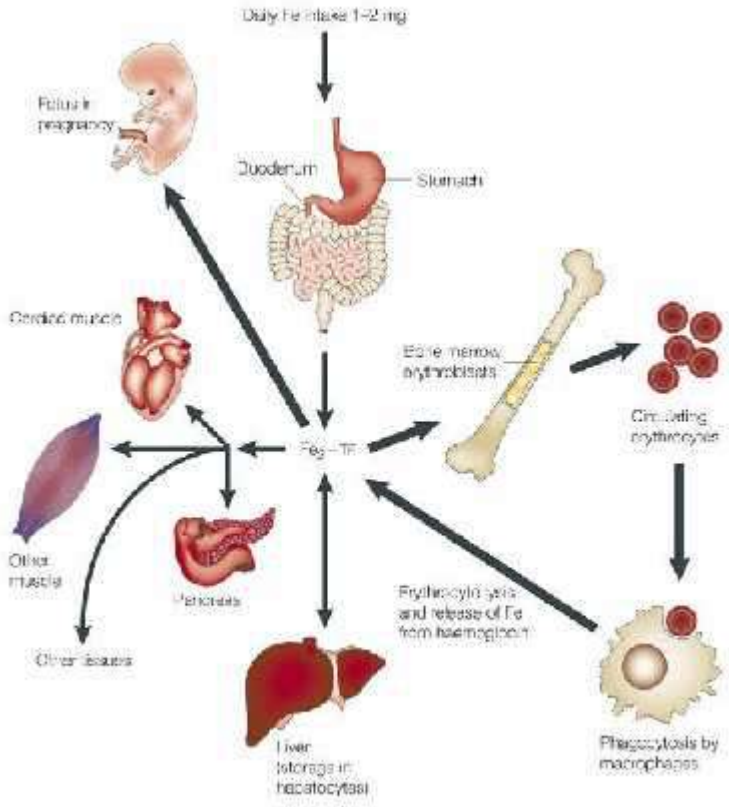

Figure 1: Iron distribution in human body

MechanismofAdaptationofIronDeficiency

The mechanisms of adaptation to iron deficiency are centered on the suppression of thehormone hepcidin and tissue hypoxia that develops consequent to anemia. The production of erythropoietinby the kidney increases in response to enhanced levels of hypoxia-inducible factor 2α (HIF-2α). As a consequence of the stimulation of erythropoietin, erythropoiesis is increased and hypochromic microcytic red cells are produced due to the low availability of iron. Senescent red cells are destroyed by macrophages and the iron found in those cells is recycled. The increase in erythropoiesis suppresses the production of hepcidin. HIF-2α increases the expression of the duodenal divalent metal transporter 1 (DMT1)(21) on the apical surface of enterocytes to increase the transfer of dietary iron from the lumen to enterocytes. Hepcidin levels are depressed in response to a reduction in the physiologic signals that maintain its production (e.g., increases in levels of iron-bound transferrin and in

the iron content of the liver),(22) to the increased activity of the inhibitor trans membrane protease, serine 6 (TMPRSS6),(23) to the reduction in levels of the activator bone morphogenetic protein 6 (BMP6), and to increased inhibition from erythropoietin-stimulated erythropoiesis. Ferroportin (FPN), which is no longer being degraded because of the low levels of hepcidin, exports the available iron across the enterocyte basal membrane and from macrophage stores to the circulation(24). Once stores are exhausted, levels of circulating iron decrease, even if absorption from the lumen is increased. Reduced levels of iron in the liver trigger increases in the synthesis of the iron carrier transferrin (referred to as apotransferrin when not bound to iron), further decreasing levels of iron-bound transferrin, the ligand of the transferrin receptor. Consequently, the uptake of iron from transferrin receptors by all cells and organs (eg. skeletal muscles and the heart) is reduced.

DietarySourcesof Iron

The most common dietary sources of iron in diets of adolescents included ready-to-eat cereal, bread, and beef. The availability of dietary iron for absorption and utilization by the body varies by its form. Heme iron, which is found in meat, fish, and poultry, is highly bio available while non heme iron, found predominantly in grains, is much less so. More than 80% of the iron consumed is in the form of non heme iron. Bioavailability of non heme iron can be enhanced by consuming it with heme sources of iron or vitamin C. Because the absorption of iron from plant foods is low, vegetarians need to consume twice as much iron to meet their daily requirement (25).

DietaryRequirementsforAdolescents

Iron is vital for transporting oxygen in the bloodstream and for preventing anaemia. For both male and female adolescents, the need for iron increases with rapid growth and the expansion of blood volume and muscle mass. Iron needs are highest during the adolescent growth spurt in males, onset of mensuration in girls and after menarche in women. The dailyrequireddietary allowance for iron is 8 mg/day for 9-13 year olds, 11 mg/day for males ages 14-18 and 15 mg/day for females ages 14-18 (26).

CausesofIronDeficiencyAnaemia

Poverty, malnutrition and famine are self-explanatory causes of anemia in the people living with iron deficiency in developing countries, especially children and pregnant women. In

addition, a cereal-based diet decreases iron bioavailability because phytates in grains sequester iron in a poorly absorbable complex. Other common causes include hookworm infections and schistosomiasis, which cause chronic blood loss(27). Strict vegan and vegetarian diets, mal absorption, and chronic blood loss resulting from heavy menstrual losses are well-known causes of iron-deficiency anemia in developed countries Chronic blood loss from the gastrointestinal tract, including occult blood may reveal the presence of benign lesions. Persons who donate blood regularly are also at risk for iron deficiency, and their iron levels should be monitored. Non-steroidalanti-inflammatory drugs and anticoagulants may contribute to blood loss, and proton-pump inhibitors are a frequently overlooked cause of impaired iron absorption(28). In developing countries, low iron intake combined with intestinal infections with nematodes may result in severe anemia, especially in young children and adolescents. In end-stage kidney disease, iron-deficiency anemia results from blood loss during dialysis, reduced hepcidin clearance, inflammation, and certain drugs (e.g. Proton-pump inhibitors and anticoagulants). In elderly persons, the prevalence of anemia correlates with advanced age and multiple related conditions, including iron deficiency, inflammatory disorders, decreased levels of erythropoietin, and cancer(29). Obesity is associated with mild iron deficiency because of subclinical inflammation, increased hepcidin levels, and decreased iron absorption(30).

ClinicalFindings

Iron-deficiency anemia is chronic and frequently asymptomatic and thus may often go undiagnosed. Weakness, fatigue, poor concentration, and poor work productivity are nonspecific symptoms associated with low delivery of oxygen to body tissues and decreased activity of iron-containing enzymes. The extent to which these non-hematologic effects of iron deficiency are manifested before anemia develops is unclear. Iron deficiency is also associatedwithpoor cognitive performance and delayedmental and motor development in children. Severe iron-deficiency anemia in pregnancy is associated with an increased risk of preterm labor, low neonatal weight, and increased newborn and maternal mortality. Iron deficiency may predispose a person to infections, precipitate heart failure, and cause restless leg syndrome. In patients with heart failure, iron deficiency has a negative effect on the quality of life, irrespective of the presence of anemia(31).

DiagnosticInvestigations

The diagnosis of anemia is made after confirmation of a reduced blood haemoglobin concentration as shown by a full blood count. Thresholds to define anemia depend on age, sex, pregnancy, altitude, and smoking. Diagnosis of iron deficiency is somewhat complex, and use of several iron status indicators in combination seems to provide the best assessment of iron insufficiency. Several laboratory markers of iron status are available. First, red cell indices on full blood counts might show a reduced mean cell haemoglobin, which corresponds to hypochromia, and a reduced mean cell volume, corresponding to microcytosis. Mean cell haemoglobin and volume are inexpensive, widely available, and sensitive measures, but become abnormal only in longstanding iron deficiency. These measures are also decreased in several chronic disease states, including haemoglobinopathies such as thalassaemia or sideroblastic anemia. In the absence of inflammation, serum ferritin measurement is the most specific test that correlates with total body iron stores. It is a universally available and standardized measurement(32). Iron deficiency is diagnosed below the cutoff of 15 μg/L in patients older than 5 years. Ferritin concentrations are increased independently of iron status in acute and chronic inflammatory disorders, malignant disease, and liver disease—a serious diagnostic limitation. In these situations, patients with a ferritin concentration of 50 μg/L or higher could still be iron deficient. In chronic kidney disease, cutoff of 100 μg/L have been suggested and 200 μg/L in case of haemodialysis. Other assays can be helpful in these disorders, such as serum iron and serum transferrin concentrations or total iron-binding capacity, which is needed to calculate the transferrin saturation. In cases of iron deficiency, serum iron is reduced and total iron-binding capacity is increased, resulting in a substantial reduction in transferrin saturation (i.e., the ratio of serum iron to total iron-binding capacity). The threshold of 16% is generally used to screen for iron deficiency, but a threshold of 20% is used in the presence of inflammation. Serum soluble transferrin receptors (sTfR) derive from proteolysis of the membrane transferrin receptor. This process shows tissue iron deficiency and inversely the amount of iron available for erythropoiesis. In case of iron deficiency, synthesis of transferrin receptors is increased, leading to a corresponding increase in sTfR. A substantial advantage of measurement of sTfR compared with other assays is that sTfR concentrations are not affected by inflammation(33). In routine practice, measurement of sTfR is not needed for a diagnosis of iron deficiency anaemia. The ratio between these receptors and the logarithm of serum ferritin (i.e., the sTfR–F index) seems to discriminate chronic disease better than either test individually(34). When the sTfR–F index

is low, anemia is probably caused by chronic disease. When it is high, iron deficiency is probably the major cause of anemia(35). Bone marrow aspiration is still thought of as the gold standard for diagnosis of iron deficiency. It is not affected by inflammation and is highly specific, but is invasive, uncomfortable for the patient, expensive, and affected by recombinant human erythropoietin. Thus, bone marrow aspiration is reserved for very specific cases, when other techniques are negative or conflicting. In cases of iron depletion, zinc transport across the intestine increases. Thus, an increased concentration of zinc protoporphyrin in erythrocytes (>80 μg/dL) is associated with iron deficiency anemia. Measurement of the proportion of circulating hypochromic red cells as a proportion of total red blood cells is the most sensitive marker of iron deficiency in patients with chronic kidney disease-6% is the cutoff(36). Unfortunately, a fresh blood sample is needed for this analysis, and automated analysers are not widely available. Reticulocyte haemoglobin content is a very early indicator of iron status, and shows available iron for erythropoiesis during the 3–4 days before measurement(37). A reticulocyte haemoglobin content of less than 27·2 pg is diagnostic. But access to this assay is poor, and false normal values can occur in patients with raised mean cell volumes or thalassaemia(38).

TreatmentforIronDeficiencyAnaemia

The treatment modalities for managing iron deficiency anaemia will depend on the underlying cause. Once the cause of iron deficiency anaemia has been ascertained, either oral or parenteral iron therapy is commonly prescribed to correct the deficiency. Oral iron therapy is usually adequate for most patients; it is an efficient, well tolerated and cost-effective way to replace iron stores. Historically, ferrous sulphate has been used to treat Iron Deficiency Anaemia because it is better absorbed by the gastrointestinal tract. Parenteral iron therapy is necessary for patients intolerant or unresponsive to oral iron supplementation(39). Historically, parenteral iron therapy has been used with caution because of its anaphylactic potential. Despite the introduction of newer intravenous iron preparations with improved safety profiles, practitioners seem hesitant to administer intravenous iron (40).

Oral Iron Therapy

The oral administration of iron is a convenient, inexpensive, and effective means of treatingpatients. Among the various iron preparations on the market, iron sulfate is the most commonly used. The recommended daily iron dosage for adults with iron deficiency is 100 to

200 mg of iron and that for children is 3 to 6 mg per kilogram of body weight for a liquid preparation. The supplement should be administered in divided doses without food. The addition of vitamin C may improve absorptionof iron. The low hepcidin levels in patients with iron-deficiency anemia ensure effective iron absorption and the rapid recovery of hemoglobin levels; however, 3 to 6 months of treatment are required for the repletion of iron stores and the normalization of serum ferritin levels. Long-term use of oral iron is limited by side effects, including nausea, vomiting, constipation, and metallic taste; these side effects are frequent and, although not severe, are often worrisome to patients. If treatment with oral iron fails, the reasons may include premature termination of treatment, lack of compliance with the regimen or discontinuation by the patient, or a truly refractory response to treatment. In the latter case, other specific treatments, such as the eradication of infection with Helicobacter pylori or the introduction of a gluten-free diet in patients with celiac disease, may restore the capacity for iron absorption and eliminate the need for supplementation in some patients(41). There are no known markers that can be used to predict which patients will or will not have a response to oral iron therapy.

Parenteral Iron Therapy

The possibility of hypersensitivity reactions (including anaphylaxis) to high-molecular-weight iron dextran has traditionally limited the indications for the intravenous administration of iron. Newly approved, safer iron formulations are modifying this clinical practice. Becausethe use of intravenous iron circumvents the problem of iron absorption, it is more effective and increases hemoglobin levels more quickly than oral iron. Another advantage is that in some patients the total dose required (up to 1000 mg) can be provided in a single infusion. The dose needed is calculated with this formula: body weight in kilograms × 2.3 × hemoglobin deficiency (target hemoglobin level − patient hemoglobin level) + 500 to 1000 mg iron for the repletion of iron stores. The cost of parenteral iron therapy is high, but the number of hospital or clinic visits that are required is significantly decreased. Intravenous administration is also preferred when a rapid increase in hemoglobin level is required or when iron-deficiency anemia caused by chronic blood loss cannot be controlled with the use of oral iron. Active inflammatory bowel disease is an emerging indication for the use of intravenous iron. Intravenous iron is essential in the management of anemia in patients with chronic kidney disease who are receiving dialysis and treatment with erythropoiesis

stimulating agents. The addition of iron supplementation may eliminate or delay the need for these agents in some patients with chronic kidney disease who are not receiving dialysis(42).

Conclusion

The prevalence of iron deficiency anaemia still remains the most common nutritional deficiency throughout the world that negatively impacts on health and development. We must move beyond current ideology, and learn how to better assess those populations at risk for the development of iron deficiency regardless of concurrent medical conditions. Evidence-based practice guidelines need to include diagnostic measures that identify changes in iron status early to avoid progression to iron deficiency anaemia, and specific management goals that include treatment strategies including what constitutes a favourable response to irontherapy along with timelines for treatment.

Abstract

Cancer is a disease of the cells in the body, which multiply at an abnormal rate. There are many different types of cancer which arise from different types of cell. Mouth cancer or oral cancer can occur in any part of the mouth, like, on the tongue's surface, in the lips, inside the cheek, in the gums, in the roof and floor of the mouth, in the tonsils, and also in the salivary glands. Oral cancers are part of a group of cancers which is commonly referred to as head and neck cancers. Brain cancer is a cancer category unto itself and is not included in the head and neck cancer group. Most commonly, oral cancers are found in the tongue and in the floor of the mouth. Anyone can get oral cancer but the risk is higher if you are male over age of 40 and use tobacco or alcohol or have a familial history of head or neck cancer. Frequent sun exposure is also a risk for lip cancer. This article gives an insight into oral cancer and its relevance to clinical practice.

Key Words:*Oral cancer, Malignancy, RiskFactors, Tobacco, Biopsy*

Introduction

Oral cancer is one of the ten most common malignancy in the world. According to the Oral Cancer Foundation, someone dies from oral cancer every hour of every day in the United States alone. Over 300,000 new cases of oral cancer are being diagnosed every year, worldwide (1). This serious condition which pertains to the mouth, lips or throat is often highly curable, if diagnosed and treated in the early stages.Mouth or Oral cancer is a sub type of head and neck cancer. It is described as any cancerous tissue growth located in the oral cavity. It may arise as a primary lesion originating in any of the oral tissues or by metastasis from a distant site of origin, or extension from a neighboring anatomic structure, such as the nasal cavity (2). Oral cancer can originate in any of the tissues of the mouth with varied histology types such as teratoma, adenocarcinoma from a major or minor salivary gland, lymphoma from lymphoid tissue, or melanoma from the melanin pigment producing cells of the oral mucosa. 90% of oral cancer are squamous cell carcinomas originating from the tissues that line the mouth and lips. Oral or mouth cancer most commonly involves the tongue and it may also occur on the floor of the mouth, cheek lining, gingiva, lips, or palate/roof of the mouth (3).

SignsandSymptoms

The most common symptoms of oral cancer are a sore or ulcer in the mouth that does not heal in a period of time, and pain and bleeding in the mouth that does not subside easily. In many cases, changes are seen in the oral mucosa before the cancer develops. A precancerous condition or premalignant lesion, is a term used to describe certain conditions or lesions involving abnormal cells which are associated with an increased risk of developing into cancer, which includes oral submucous fibrosis, leukoplakia, erythroplakia, actinic keratosis, oral lichen planus, oral candidiasis, syphilitic glossitis and carcinoma in situ. This means that early treatment of these changes will actually prevent a cancer from developing. (4) Some characteristic signs of oral cancer are, a lump on the lip, tongue or in the mouth or throat, unusual bleeding or numbness in the mouth, pain when chewing or swallowing, poor periodontal condition or dentures not fitting properly, a change in the voice or speech problems and weight loss. If the cancer spreads to other parts of the body, various other symptoms can develop. All of these symptoms can be due to

other conditions, so tests are needed to confirm the diagnosis. (5) Cancer begins with a change in the structure of DNA. DNA provides our cells with a basic set of instructions, such as when to grow and reproduce. A change in DNA structure is known as a mutation, and it can alter the instructions that control cell growth. This means that cells continue to grow instead of stopping when they should. This causes the cells to reproduce in an uncontrollable manner, resulting in a lump of tissue called a tumor.(6,7)There are two ways mouth cancer can spread, directly – the cancer can spread from the mouth and into nearby tissues, such as surrounding skin or into the jaw and through the lymphatic system. The lymphatic system is a series of glands or nodes located throughout the body, which produce many specialized cells, needed by the immune system to fight infection. Oral cancer that spreads to another part of the body is known as metastatic oral cancer. (8, 9)

RiskFactors

The most commonly known risk factors that cause oral cancer include:

Smoking and Alcohol

The two leading causes of oral cancer are smoking cigarettes or other tobacco products, such as pipes or cigars and consuming too much alcohol. Both of these substances are carcinogenic, which means they contain chemicals that can damage the DNA in cells and lead to cancer. (10) The risk of oral cancer increases significantly in those who smokes and drinks heavily. Research has shown that if they smoke 40 cigarettes a day, but do not drink alcohol, they are five times more likely to develop oral cancer than someone who does not drink or smoke. If they do not smoke, but consume an average of 30 pints of alcohol a week, their risk also increases by a factor of five.(11) Smoking more than 40 cigarettes a day and consuming an average of 30 pints of alcohol a week, they are 38 times more likely to develop oral cancer.(12)

Tobacco

Tobacco is used in both smoke and smokeless forms. Smoking forms are more common in western countries compared to the Middle East and eastern countries. Smoking form includes the use of beedis and cigarattes predominantly with various aids like hooka, hookli, chutta, dhumthi, chillum. However the higher pricing of these products compared to other forms makes this more common amongst the middle and upper socioeconomic classes of population. Beedi is a smoking stick made by rolling a dried piece of rectangular temburni leaf (Diospyrosmelanaxylon) with sun-dried, flaked tobacco arranged in a conical shape. The roll is then secured with the thread. Chutta is a kind of reverse smoking wherein the burnt end is kept inside the mouth. It is made up of coarsely prepared roll of tobacco and prevalent in South-eastern parts of India. Dhumthi is another type of smoking forms made by rolling the tobacco leaves inside the leaf of the jackfruit tree. Hooka is made using metallic or wooden pipes and used for smoking tobacco. This device consists of a spherical receptacle, containing water with aromatic substances. Hookli is another form of smoking tobacco device which employs a short clay pipe like device. Chillum is a conical clay pipe used to smoke tobacco and tobacco with ganja in northern parts of India. The narrow end of this device is put inside the mouth and wrapped in a wet cloth to act as a filter. (13) The smokeless forms of tobacco includes betel quid, khaini, mawa, snuff, gutka and pan masala. Betel quid consists of areca nut, slaked lime, tobacco mixed and folded in a betel leaf and placed either in the buccal or labial vestibule. Khaini is prepared by mixing roasted tobacco flakes and slaked lime and the mixture is placed in the lower buccal or labial sulcus. Mawa is a mixture of areca nut, tobacco and slaked lime. Snuff is a blackish brown powder obtained from tobacco through roasting and pulverisation. It is generally used through nasal insufflations or applied on the gums by using a finger. Gutka is a mixture of areca nut, tobacco and few other condiments, which are marketed in different flavors in colorful pouches. Pan Masala may or may not contain tobacco, with areca nut and few other condiments. (14)

Human PapillomaVirus (HPV)

Human Papilloma viruses, belong to a family of viruses that affect the skin and moist membranes lining the body, such as those in the cervix, anus, mouth and throat. An individual can be

infected with Human Papilloma Virus by having sexual conduct with a person already infected. (15, 16) There is evidence that some types of HPV infection could also cause abnormal tissue growth inside the mouth, triggering some cases of mouth cancer. (17, 18) HPV infection is the probable cause of mouth cancer in young people who have few or none of the expected other risk factors.

Diet

There is evidence that a diet high in red meat, processed food and spicy food can increase the risk of developing oral cancer. (19) High consumption of deep fried foods was associated with an elevated risk of oral cancer. Heterocyclic amines and other substances produced by heating meat and fish, particularly at high temperatures, as used in deep frying, have been shown to be mutagenic and carcinogenic in animal models (20).

Diagnosis

The dentist should check the mouth and throat for red or white patches, lumps, swelling or other problems, carefully at the roof and floor of the mouth, back of the throat, and insides of the cheeks, gingiva and lips and also in the lymph node regions. If an individual shows an abnormal area in the oral cavity, a small sample of tissue may be excised. (21) Excising tissue to look for cancer cells is called a biopsy. Usually, a biopsy is done with local anesthesia and sometimes, it is done under general anesthesia. Followed by this, an oral pathologist examines the tissue under a microscope to check for the growth of malignant cells. (22)

ExfoliativeCytology

In this method, the dentist scrapes the affected area and smears the collected tissue onto a glass slide. The sample is then stained with a dye, which aids by making the cells visible under the microscope. If the cells examined are found to be abnormal, then the area can be biopsied. (23)

Incisional Biopsy

Here, the dentist excises a small piece of tissue from the affected area. This is the most common type of biopsy applied to sample areas in the mouth or throat. Biopsy can be done either in the dentist's office or in the operating room, depending on where the tumor is and how easy it is to get a good tissue sample. If it can be done in the dentist's office, the area around the tumor will be anaesthetized before the biopsy is taken and if the tumor is deep inside mouth or throat, the biopsy might be done in the operating room with the patient under general anesthesia. (24)

Fine NeedleAspirationCytology (FNAC)

For this test, the dentist uses a very thin, hollow needle attached to a syringe to aspirate some cells from a lump. These cells are then examined under a microscope to see if malignant cells are present. FNAC is not used to sample abnormal areas in the mouth or throat, but sometimes used when a patient has a neck mass that can be felt or seen on a CT scan. (25)

HPV Testing

In case of nasopharyngeal cancers, the dentists often have the biopsy samples to be tested for HPV infection, as it is likely to be the cause. This information can help the dentist to predict the probable course of the cancer and thetreatment to be done. (26)

ImagingTests

Imaging tests involve the use of x-rays, magnetic fields, or radioactive substances to create/reproduce pictures of the inside structures of the body. Imaging tests are often not used to diagnose oral cavity or oropharyngeal cancers, but they may be done for a number of reasons both before and after a cancer diagnosis, including to help look for a tumor if one is suspected, to learn how far cancer may have spread, to help determine if treatment has been effective and for possible signs of cancer recurrence after treatment. (27)

Computed Tomography (CT)

The computed tomography (CT) scan produces detailed, multiple cross-sectional images of the body. A computer then combines these images into a single image. A CT scan creates detailed images of the soft tissues and organs in the body compared to that of regular X rays. This test can help the dentist to determine the size and location of a tumor, if it is spreading into nearby tissues, and if to lymph nodes in the neck and the test also may be done to look for spread of cancer to the lungs. (27)

Magnetic ResonanceImaging (MRI)

Magnetic resonance imaging (MRI) scans use strong magnets and radio waves instead of x-rays. The energy from the radio waves is absorbed by the body and then released in a specific pattern formed by the type of body tissue and by certain diseases. A computer translates the pattern into a very detailed image of parts of the body. (27) This test can help the dentist to determine the spread of the cancer into adjacent soft tissues and other body parts.

Staging

Staging of oral cancer is important for establishing proper treatment and determining prognosis. Tumors are staged using the TNM system, where T represents the size of the primary tumor, N indicates the status of the regional lymph nodes, and M indicates the presence or absence of distant metastases. (28)

Primary Tumor (T)

TX - Primary tumor cannot be assessed

T0 - No evidence of primary tumor

T_{is} - Carcinoma in situ

T1 - Tumor $\leq$ 2 cm in greatest dimension

T2 - Tumor $\geq$ 2 cm but $\leq$ 4 cm in greatest dimension

T3 - Tumor $\geq$ 4 cm in greatest dimension

T4 - (lip) Tumor invades through cortical bone, inferior alveolar nerve, floor of the mouth or the skin of the face i.e., chin or nose

$T4_a$ - Moderately advanced local disease

(Lip) Tumor invades through cortical bone, inferior alveolar nerve, floor of the mouth or the skin of the face i.e., chin or nose

(Oral cavity) Tumor invades adjacent structures (eg. through cortical bone [mandible or maxilla] into the deep extrinsic muscles of the tongue (genioglossus, hyoglossus, palatoglossus and styloglossus), maxillary sinus or skin of the face

$T4_b$ - Very advanced local disease

Tumor invades masticator space, pterygoid plates, or skull base and/or encases internal carotid artery

Regional LymphNodes (N)

NX - Regional lymph nodes cannot be assessed

N0 - No involvement of regional lymph nodes

N1 - Metastasis in a single ipsilateral lymph node, $\leq$ 3 cm in greatest dimension

N2 - Metastasis in a single ipsilateral lymph node, $\geq$ 3 cm$\leq$ 6 cm in greatest dimension; or in multiple ipsilateral lymph nodes, none $\geq$ 6 cm in greatest dimension or in bilateral or contralateral lymph nodes, none $\geq$ 6 cm in greatest dimension

$N2_a$ - Metastasis in a single ipsilateral lymph node, but $\geq$ 3 cm$\leq$ 6 cm in greatest dimension

$N2_b$ - Metastasis in multiple ipsilateral lymph nodes, none $\geq$ 6 cm in greatest dimension

$N2_c$ - Metastasis in bilateral or contralateral lymph nodes, none $\geq$ 6 cm in greatest dimension

N3 - Metastasis in a lymph node, $\geq$ 6 cm in greatest dimension

Distant Metastasis (M)

M0 - No distant metastasis

M1 - Distant metastasis

Treatment

Many treatment options for oral cancer are applied, which include radiotherapy, surgery, and chemotherapy. The treatment advised for each case usually depends on various factors such as the exact site and extent of the cancer, and your general health.

Surgery

The most common treatment for oral cancer is surgery. The type of surgery depends on the size of the cancer and its site. The surgery is done by removing the cancerous growth and some of the surrounding normal tissue. The main aim of surgery is by curing the cancer by removing it all and sometimes is used to relieve symptoms if the cancer is an advanced stage (palliative surgery). Surgery with lasers may sometimes be used to remove small oral cancers and this may be combined with a light sensitive drug in treatment known as photodynamic therapy. A surgery called micrographic surgery or Mohs' surgery is done for cancers on the lip. In this surgery, the surgeon removes the cancerous growth in very thin layers. The tissue that has been removed is examined under a microscope during the operation. This technique makes sure that all the cancer cells are removed and only a very small amount of healthy adjacent tissue is removed. (29)

Radiotherapy

Radiotherapy uses high energy beams of radiation, which are targeted on the cancerous tissue for a limited period of time. This kills malignant cells, or stops malignant cells from multiplying further. Two types of radiotherapy are used for mouth cancer, namely, external radiotherapy and internal radiotherapy. (29)

External Radiotherapy

In this method, the radiation is targeted on the cancerous growth from a machine. This is the common type of radiotherapy which is used for many types of oral cancer as a general treatment.

Internal Radiotherapy (Brachytherapy)

This treatment is basically done by placing small radioactive wires adjacent to the malignant growth for a short period of time and then they are removed after a period of time.

Chemotherapy

In chemotherapy, anti-cancer drugs are used to kill the malignant cells, or to stop them from multiplying. Chemotherapy may be used in conjunction with radiotherapy or surgery. Chemotherapy may also be advised if the cancer has spread to other areas of the body. (29)

Conclusion

Of all sites in the head and neck region, lesions found in the oral cavity should be amenable to early detection because the oral mucosa is accessible for viewing by both the patient and general health care professionals. Furthermore, the rich innervation of oral mucosa ensures that even small lesions are likely to elicit tenderness or erythema. Oral cavity lesions are commonly seen in both smokers and alcoholic drinkers, but also an alarming increased frequency is seen along the lateral side of the tongue in non-smokers. Early detection is the first step toward the overall goal of early treatment, which holds the promise of greater efficacy, since single modality treatment is sufficient in many cases. Early diagnosis is facilitated by the accessibility to biopsy without general anesthesia. Educating the general population about oral cancer is a must to bring down mortality and morbidity arising out of it and improve the quality of life of the population.

Anaemia Associated with Chronic Heart Failure

Priyadharshni S[1], Naufal Rizwan[2], E. Roja[3]

Abstract

Anemia has been identified as an independent prognostic factor of both morbidity and mortality for patients with congestive heart failure (CHF). The association between anemia and adverse outcomes has raised the hypothesis that anemia correction might lead to an improvement in the prognosis of patients with CHF. Nevertheless, data from large randomized trials about the effect of anemia correction on patient outcome are still lacking. Numerous clinical studies, randomized and nonrandomized, have evaluated the efficacy of erythropoietin or iron supplementation for treating anemia in patients with CHF, and their effect on patient symptoms and functional status. The superiority of any of these approaches has not been established yet. This review will discuss different treatment options for anemic patients with CHF, with emphasis on the correction of iron deficiency. Since anemia is an independent risk factor for adverse outcomes in HF, it is reasonable to assume that correction of anemia should improve the prognosis of patients. How- ever, this has not been proved in adequately powered trials yet.

Several studies, both randomized and nonrandomized, have implemented different treatment strategies and investigated the impact of anemia correction on the functional status of patients with CHF. The treatment strategies are: 1) erythropoietin-stimulating agents (ESA), 2) iron supplementation, and 3) both of them. Severe anemia results in the activation of the sympathetic and renin-angiotensin systems, similarly to CHF, potentially leading to exacerbation of these maladaptive responses. Whether this is the case with less severe anemia remains unclear. Anemia is more common in patients with renal failure. The risk of death in anemic patients with CHF and chronic kidney disease (CKD) is increased compared with anemic patients with normal renal function.

Keywords*:Heart failure, patients, anaemia, kidney, haemoglobin.*

Introduction

Anemia is found in about one-third of all cases of congestive heart failure (CHF).Anemia is common and is a powerful independent predictor of death and hospitalization in a broad spectrum of patients suffering from systolic and diastolic dysfunction, new-onset Heart failure and advanced chronic Heart failure. Anemia and chronic renal disease are often present in Chronic Heart failure, one exacerbating the other (cardio-renal anemia syndrome). Chronic renal disease is likely due to the renal vasoconstriction. This reduces the amount of erythropoietin produced in the kidney and leads to anaemia. The anemia itself can worsen cardiac function, as it causes cardiac stress through tachycardia and increased stroke volume, and because it can cause a reduced renal blood flow and fluid retention, adding further stress to the heart. Iron deficiency appears to be the most common cause of Anemia in Heart Failure. Long-standing anemia of any cause can cause left ventricular hypertrophy (LVH), which can lead to cardiac cell death through apoptosis and worsen the CHF. Anaemia thus plays an important role in both the initiation and the progression of heart failure. Recent studies shows that low levels of haemoglobin or haematocrit are associated with a reduced exercise capacity, an increase in hospitalisations and poorer long-term survival.Heart failure (HF) is a common disease associated with poor prognosis. Anaemia is commonly associated with HF due to bone marrow depression, reduced availability of iron and haemodilution, and is sometimes aggravated by too frequent blood testing. Low haemoglobin is very detrimental to the haemodynamic state of the patient with decreased cardiac output as it further diminishes the oxygen supply to the tissues. When anaemia is associated with HF and renal failure, the patient enters a vicious cycle called cardio renal anaemia syndrome. In India, the prevalence of anemia is 2.5% in women and 1% in men associated with chronic heart failure.

Etiology

The etiology of anaemia in HF is multifactorial, including bone marrow depression due to chronic inflammation with production of pro-inflammatory cytokines and induced erythropoietin resistance and reduced availability of iron and heamodilution secondary to sodium and water retention(1).The low iron level, due to reduced content of iron in the diet and also reduced iron absorption, is often present in patients with HF(2).The renin-angiotensin system also plays important role in the regulation of plasma volume and red blood cell volume. Increased angiotensin II signalling in the kidney alters peritubular oxygen

tension, and increases erythropoietin secretion by reducing renal blood flow and increasing proximal tubular reabsorption(3).Angiotensin II may also have direct stimulatory effects on bone marrow erythrocyte precursors. Erythropoietin levels are modestly increased in patients with CHF in proportion to measures of activation of the renin-angiotensin system. Inhibition of the Renin angiotensin system with either ACE inhibitors or angiotensin receptor blockers is associated with decreased erythropoietin production and reduced haemoglobin levels(4). Angiotensin converting enzyme inhibitors, which are commonly used in CHF treatment, can be associated with low hemoglobin, probably by suppression of erythropoietin. Inflammatory cytokines, such as interleukin (IL)-1 and IL-6 and tumor necrosis factor (TNF)-α, which are elevated in severe HF, can also reduce production of erythropoietin or increase resistance to its action.Chronic kidney disease (CKD) is a common comorbidity in patients with CHF, due to low cardiac output and poor organ perfusion. In CKD with HF, where glomerular filtration rate is below 60 mL/ min, erythropoietin production is reduced, resulting into poor hematopoietic and anemia. Finally, concomitant anti-platelet or anticoagulant therapy increases the possibility of gastrointestinal blood loss(5).Inflammatory cytokines, like IL-1 and IL-6 are often raised in patients with severely symptomatic HF patients and may contribute to anemia by various mechanisms, i.e. by (i) promoting iron storage by the reticuloendothelial system, thus not available for hemoglobin synthesis, (ii) increased circulatory levels of inflammatory cytokines, such as IL-6 and TNF-α, found in CHF also inhibits renal production of erythropoietin by activating GATA 2 binding protein and nuclear factor-kB, (iii) increased levels of TNF-α and IL-6 inhibits the proliferation of bone marrow erythroid progenitor cells thus again retarding hematopoiesis(6).

Iron deficiency anemia (IDA) plays an important role in etiology of anaemia in chronic heart failure. Iron deficiency may be absolute or functional. Absolute deficiency of iron is termed when iron stores are depleted as indicated by low serum ferritin, i.e. less than 30 µg/L, which may be due to (i) insufficient dietary iron supply, (ii) intestinal malabsorption, impaired duodenal iron transport, drug interactions (e.g. omeprazole), or food reducing absorption and (iii) gastrointestinal bleeding(7).The possible mechanism of functional IDA appears to be related to hepcidin, a protein which plays central role in the regulation of iron metabolism. Hepcidin levels are elevated in the initial stages of CHF but falls as the disease progresses; low levels are an independent marker of worse prognosis. Hepcidin binds to ferroportin, which is the only protein that is able to export intracellular iron. Ferroportin is degraded by hepcidin preventing iron from re-entering cells. T his reduces iron absorption in

the duodenum and causes iron to be retained in the reticuloendothelial system, reducing its concentration and availability in target tissues. Hepcidin also plays a part in erythropoiesis and in the innate immune response to pathogens(8).

Pathophysiology

Anemia is a problem in various chronic conditions such as renal disease, cancer, infection, and heart disease.These patients are frequently anaemic in the absence of vitamin or mineral deficiencies, hemolysis, or other definable causes. When the etiology of anemia does not appear to be predominantly due to hematinic deficiencies,it is referred to as “anemia of chronic disease.”Patients with anemia usually will have volume overload in vascular system, and oxygen carrying capacity is reduced, in turn leads to compensatory tachycardia and with greater demands on energy expenditure. The increased plasma volume produces eccentric hypertrophy, where ventricular dimension increases disproportionally to the ability to increase wall thickness. Systolic cardiac function may not be altered much in the presence of moderate anemia and in the absence of underlying heart disease. However, in patients with pre-existing damaged heart, systolic function may be low and may add to hemodynamic worsening(9). The ventricular dysfunction is usually reversible with correction of anemia, as seen in a study done in children with severe IDA, where the ratio of LV end-systolic wall stress to the LV volume index (and cardiac index) decreased when hemoglobin concentration was very low, i.e. 6 g/dL, indicating a decrease in LV contractility and LV dysfunction, but this improved after anemia correction with iron replacement, before the rise in hemoglobin level, suggesting that correction of functional abnormalities may also be the result of correction of iron metabolism at the tissue level(10).A circulating hormone called erythropoietin, 80% to 90% of which is produced in the kidneys, is the principal factor that stimulates RBC production. When HF patients have concomitant renal disease, they invariably become anemic owing to erythropoietin deficiency.In chronic HF patients without renal disease, erythropoietin levels may be elevated in response to anemia, but not adequately increased to overcome the anemia.Some degree of erythropoietin resistance may also be present because of elevated plasma levels of inflammatory cytokines.Increased erythropoietin production in HF is thought to be related to decreased renal blood flow and increased proximal tubule sodium reabsorption caused by renin-angiotensin activation. Many HF patients have concomitant renal insufficiency or failure, and consequently may have a combination of factors contributing to the development of anemia. Compared with non

anemic HF patients, those with anemia tend to have a history of hypertension or chronic renal insufficiency. Another identified causes of anaemia in heart failure include an increase in pro inflammatory state including tumor necrosis factor, interleukin IL-1 and IL-6. This pro-inflammatory state can contribute to anemia through a number of mechanisms, including suppression of erythropoietin (EPO) secretion by the kidney, decrease bone marrow responsiveness to EPO and a decrease in iron bioavailability for Hb production. IL-6 is also known to increase the production of hepcidin by the liver, which will lead to a decrease in gastrointestinal iron absorption, further decreasing iron bioavailability(11). Tryptophan is essential for cellular growth. Thus, tryptophan depletion is capable of inhibiting cell proliferation and may contribute to development of T-cell unresponsiveness. Earlier enhanced tryptophan degradation was shown in patients with congestive heart failure and in patients suffering from other chronic diseases. Recently, de- creased hematopoiesis was found in the bone marrow of mice with heart failure.Thus, enhanced degradation of tryptophan could also be the rate-limiting step in hematopoiesis. Consequently , in several diseases with chronic immune activation and concomitant release of IFN- , an increased activity of indoleamine-2,3-dioxygenase could be involved in the drop of hemoglobin and the development of anemia.

Clinical Outcomes

The symptoms of anemia consist of fatigue, mild dyspnea on exertion, and occasionally palpitations. Patients may describe the palpitations as being aware of their heart beating or feeling their heart pounding. Lower Hb concentrations are associated with worse HF symptoms and poorer (higher) NYHA class. Even when it is severe, anemia rarely provokes angina in patients without ischemic heart disease, and, in fact, the prognostic impact of anemia was independent of ischemic heart disease in one large retrospective study. Anemic patients may appear pale, but pallor of the conjunctivae and nail beds is a more reliable sign, particularly in patients of color. An S3 extracardiac sound is often auscultated at the cardiac apex. Jugular venous distention is uncommon, but may occur with peripheral edema and hepatomegaly in the presence of hemodilution as a result of fluid volume overload. Hemodynamic parameters of anemic HF patients in one study revealed lower blood pressure, higher heart rate, and elevated pulmonary capillary wedge pressure. On the basis of HF patient profiles from several studies, patients who are anemic tend to be older, female, and have more severe symptoms and signs of HF. They also tend to have greater cardiac

functional impairment and higher hospitalization rates. In addition, they often have a history of diabetes, renal insufficiency, hypertension, and they are often on diuretic medications(12).In patients presenting with diastolic dysfunction, anemia has been associated with increased mortality, higher likelihood of hospitalization,higher serum concentrations of brain natriuretic peptide, decreased exercise capacity, and longer hospitalizations.It is also note worthy that in a broad population of patients presenting with chronic HF, including patients with diastolic dysfunction, 70% were lymphopenic, suggesting a more widespread disturbance of hematopoiesis in some patients, perhaps due to suppression of the bone marrow by elevated cytokine concentrations. The underlying mechanisms behind this close relationship between anemia and fatal events remain unclear. Potential explanations include neurohormonal hyperactivity, changes in ventricular loading conditions, and a reduced free radical scavenging capacity(13). Chronic anemia may also adversely affect large blood vessels, resulting in arterial hypertrophy and remodeling, occurring as a result of sustained increases in cardiac output. In theory, this may reverse the early vasodi- latation characteristic of anemia and lead to increased systemic vascular resistance, which further contributesto the development of LVH. Early on, these changes may be reversible; however, in conditions such as CKD, they may become permanent. It is important to recognize that, although studies may demonstrate an association between anemia and CVD outcomes, this does not necessarily imply that anemia is the cause and, therefore, a treatable cause of CVD. That is, confounding from unmeasured factors, or residual confounding from measured factors may be playing a role. Two examples include the following: (1) anemia may be associated with an unmeasured risk factor, such as inflammatory status, which in turn is the cause of both the anemia and the causal risk factor associated with

CVD; and (2) anemia may be a marker of the severity of underlying heart disease. For example, in patients with heart failure, anemia may be due to hemodilution associated with the severity of heart failure.

Role of Inflammation

A commonly entertained but still mostly unproven mechanism is that anemia in heart failure resembles anemia of chronic disease as evidenced by iron acquisition in the reticuloendothelial system. Plasma levels of tumor necrosis factor-alpha (TNF-á), interleukin-1, and interleukin-6 are elevated in severely symptomatic patients with heart failure, promoting iron storage by the reticuloendothelial system, likely contributing to the

anemia inflammatory cytokines, such as interleukin-6 and TNF-á, have been shown to inhibit renal production of erythropoietin by activating GATA 2 binding protein and nuclear factor-kB. High levels of TNF-á and interleukin-6 have a tendency to inhibit proliferation of bone marrow erythroid progenitor cells. Hepcidin, an acute phase reactant with intrinsic antimicrobial activity, is synthesized in the liver. Of the two known isoforms, hepcidin-25 plays a key role in iron homeostasis, while the role of hepcidin-20, which lacks the five amino acid sequence, thought to be crucial for iron regulation, remains unclear.Hepatic production of hepcidin is stimulated by interleukin-6, resulting in impaired duodenal iron absorption and down-regulation of ferroportin expression, preventing release of stored iron. Anemia of chronic disease and iron deficiency anemia may coexist in patients with congestive heart failure, complicating the clinical picture, and one may need to measure soluble transferrin receptors and ferritin levels for further delineation.Anemia of chronic disease rather than iron deficiency anemia is far more frequent in patients with heart failure.Although the precise mechanisms are incompletely understood, both inflammatory stress and impaired iron metabolism appear to play a role.

Anemia in an aging population can be further complicated by other factors, including reduced stem cell production, low hematopoietic growth factor production, and altered sensitivity to hematopoietic cytokinesIn addition, higher levels of proinflammatory cytokines, such as interleukin-1, TNF-á, and interleukin-6, are noted in a variety of diseases unique to the elderly population, ie, atherosclerosis, diabetes mellitus, and cancer. Although, there are some data to suggest that carnitine supplementation leads to improvement in anemia and possible reduction in erythropoietin-stimulating agent (ESA) requirements in patients with end-stage renal disease on hemodialysis, the role of carnitine supplementation is yet to be explored in anemic patients with heart failure.

Erythropoietin Production and Resistance

Erythropoietin, a highly glycosylated (40% of total molecular weight) proerythrocytic hormone with a half-life of around 5 hours, is a crucial component of the hematopoietic system in regulation of red blood cell production, and subsequently affects tissue oxygen delivery. Specialised peritubular fibroblasts located in the cortex and outer medulla are responsible for the majority of renal erythropoietin production (90%), while the remainder is synthesized in the liver.Renal hypoxia is the main stimulus for erythropoietin production, resulting in an exponential increase in the number of erythropoietin-producing

cells.Not surprisingly, this response is blunted in patients with chronic kidney disease. Renal blood flow is relatively well maintained in patients with heart failure until the late stages, especially in patients on angiotensin-converting enzyme inhibitors. Renal hypoxia in this setting is more likely due to the presence of local arteriovenous shunts in the intrarenal circulation, resulting in a substantial reduction in oxygen tension and stimulation of erythropoietin production. Defective erythropoietin production was demonstrated in more than 90% of patients with heart failure and laboratory evidence of anemia of chronic disease. In contrast with earlier studies, more recent studies have failed to demonstrate a significant correlation between erythropoietin production and effective renal plasma flow in the setting of heart failure.A weak but significant correlation between erythropoietin production and estimated glomerular filtration rate indicates that renal dysfunction plays a role in the blunted production of erythropoietin in anemic patients with heart failure.

Management of Anaemia Associated with CHF

The primary aim of treatment of HF and anemia is to fulfill the need of oxygen for metabolic performance of the heart and to achieve this, the concentration of hemoglobin should be normal. Though there is no universally agreed target hemoglobin level; however, hemoglobin of 12 g/dL level in patients with CHF is regarded as optimum for adequate myocardial performance. The anemia in HF increases the symptoms of poor functional capacity and is also responsible for frequent rehospitalization and increased mortality. Proper correction of anemia in HF can modify the outcome of patients. It is most important to recognize the cause of anemia like blood loss, poor nutrition and any drug and then manage accordingly.(14)

Iron Therapy

While treating with different intravenous (IV) iron agents, the main concerns are intolerance and occasional anaphylaxis. Most commonly used iron preparation in past was iron dextran complex. Dextran forms outer shell to cover trivalent iron, but it may lead to anaphylactic reaction; hence, nowadays dextran-free preparation are preferred. Other available IV iron preparations are iron hydroxide sucrose, iron gluconate, and iron hydroxide dextran. Recently, new formulations have been introduced such as ferumoxytol in

the US and ferric carboxymaltose in Europe. Several new compounds are also in development but have yet to be tested in patients with CHF. Whether iron replacement therapy helps in clinical improvement, left ventricular function or reduces morbidity and mortality remains another challenge. Many studies were designed with different forms of iron preparation to assess the efficacy and outcome. Oral administration of iron salts is inexpensive and convenient, but unfortunately often poorly tolerated and unreliable. Iron absorption depends on the acidity level in the stomach; thus food, antacids, and proton pump inhibitors impair the response to oral iron. Many patients experience gastric irritation when taking iron on an empty stomach. For this reason, it is our practice to recommend IV iron to most EPO-treated patients who require iron. Prior to the last few years, the only IV iron available was iron dextran, the administration of which was not infrequently associated with symptoms ranging from mild urticaria to full-blown anaphylactoid reactions, which were occasionally lethal. Fortunately, currently available parenteral iron formulations include iron sucrose and ferric gluconate, both of which are extremely safe.The incidence of allergic and other adverse reactions to either of these medications is so low that test doses in advance are not required.(15)

Erythropoietin Stimulating Agents

Erythropoietin, a proerythrocytic hormone has a crucial role in the hematopoietic system in regulation of red blood cell production. It is produced in peritubular fibroblasts located in the cortex and outer medulla of kidney. Renal hypoxia is the main stimulus for erythropoietin production. Erythropoietin levels are modestly elevated in patients with CHF, but the increase is less than that observed in other anemic populations. Erythropoietin stimulates red blood cell production by inhibition of apoptosis of bone marrow erythrocyte progenitors. Bone marrow erythroid progenitor cells escape from apoptosis and proliferate to result in the growth and maturation of proerythroblasts and normoblasts. Subsequently there is increase in reticulocytosis and hemoglobin level. The rationale for using erythropoiesis-stimulating agents (ESAs) is that although anemia in CHF is multifactorial, like low cardiac output related poor renal perfusion and ACE inhibitor therapy, which is given to almost all patients with HF, and has been shown to downregulate erythropoietin system thus contributing to anemia(16).

Conclusion

High morbidity and mortality due to CHF has major impact on health care system. Anemia is one of the common and significant comorbidity in CHF, more so in the elderly population. Anemia itself is an independent prognostic factor in the majority of HF patients. Anemia always has negative impact on course of CHF patients, as oxygen carrying capacity is reduced critically which adds to further jeopardy of failing myocardium. There are several mechanisms contributing to low hemoglobin levels in the HF patients, some of which still remains unexplained; however, available evidences suggest that it is due to complex interaction of underlying iron deficiency due to GI blood losses, and impaired absorption and availability of iron, defective erythropoietin production, resistance, and activation of the renin-angiotensin-aldosterone system, along with the presence of underlying CKD and activation of proinflammatory cytokines. The reduced hemoglobin may merely be a marker for the epiphenomena of advanced HF such as hemodilution due to volume overload, malnutrition from cardiac cachexia, or renal insufficiency. All efforts should be directed for early recognition of anemia in HF patients, discern the pathophysiology of, and test the new therapies for anemia in HF. The correction of anemia is not a substitute for the well-documented effective therapy of CHF but seems to be an important addition to current armamentarium. It is surprising, therefore, that judging from the literature on CHF, such an obvious treatment for improving CHF is so rarely considered. We believe that the correction of the anemia will have an important role to play in the amelioration of cardiac insufficiency, and that this improvement will have significant economic implications as well. Also it is necessary to elucidate whether there are different responses on end points of patients with ischemic HF in comparison to those with nonischemic CHF.

Abstract

Successful endodontic therapy requires proper diagnosis of root canal morphology along with an understanding of possible variations in canal morphology that affect treatment. Failure to do so can lead to improper endodontic treatment that may eventually result in endodontic failure. Mandibular first molars are treated commonly on the assumption that they have 2 or 3 canals. Studies have however shown a significant incidence of another middle mesial canal in these teeth. Unfilled canals, can compromise the longevity of the tooth, thus being a source of infection.

Key Words: *Mandibular first molar, middle mesial canal, radix entomolaris, c shaped canal, canal anatomy.*

Introduction

The root canal treatment requires proper knowledge of variations in root canal morphology in order to recognise, disinfect and seal all possible root canals. This can be accomplished with proper diagnosis using newer technologies, modification in access preparation, use of operating microscope, enhanced methods of disinfecting and sealing of all canals [1]. The mandibular first molar is the first posterior tooth that erupts and is the tooth that most often requires root canal treatment. This tooth usually has two roots, one mesial and one distal. Usually, the distal root is found to have one root canal and the mesial root is found to have two root canals. But occasionally, it has three roots with two or three canals in the mesial root and one, two, or three canals in the distal root [2].

Teeth do not always have the same internal anatomy. The anatomical variations in number of roots, number of root canals, or even the shape of root canals is often encountered. Many clinicians used to treat every tooth like being a standard one. In these cases, many failures occurred. In time, other practitioners studied the anatomy of root canal systems and their anatomical variations and they found out that there are many different types of teeth. The respective studies provide information that, if taken into account, might improve the outcome of endodontic treatment. The main goal of endodontic therapy is to prevent or heal apical periodontitis. From a biomechanical perspective this means cleaning, shaping, and disinfection that would allow for three-dimensional obturation of the root canal system. However, the complexity of the root canal anatomy presents clinical challenges and difficulties that often jeopardize the primary goal of such therapy. Knowledge of both normal and abnormal anatomy dictates the parameters of root canal therapy and can directly affect the probability of success. Thus, like for any surgical procedure, endodontic therapy should be preceded by a thorough knowledge of pulp chamber and root canal anatomy. Once this complex anatomy has been accessed, the outcome is directly related to the elimination and prevention of microbial contamination

Figure1: Access Cavity of a Mandibular First Molar with 3 Canals.

The tooth generally has two separate roots with a round, or more frequently elliptical, canal in the distal root (Fig. 1) and two canals in the mesial root [5]. Previous in vitro and in vivo reports have indicated that mandibular molars can have more than three root canals. Root canal morphology and configuration have been classified and widely known by Weine and Vertucci[3,9].

The main etiology of failure in endodontic treatment of molars is the partial removal of pulpal tissue of root canal systems, the infection of the remaining tissue and the consequent long-termfailure. To be successful, it is necessary to clean and shape the root canals completely and fill the total area with an inert material. A morphological study of root canals is of extreme importance to effective endodontic treatment, and much attention must be paid to their internal anatomy. In addition, to achieve success in endodontic treatments, the number, localization, shape and direction of root conducts must be considered. With the advent of surgical microscopes, the detection of additional root canals has increased and provided higher pre-visibility to the treatment area, since the complexity of root canal systems is the greatest challenge to the endodontist from both a technical and a microbiological point of view. The first permanent mandibular molars generally present two roots containing two canals on the mesial root and one canal on the distal one. Occasionally, however, they may present a third canal on the mesial root, localized between the mesiovestibular and mesiolingual canal, which deserve special attention during the exploration of the pulp chamber before beginning endodontic treatment. The incidence of this third canal on the mesial root varies from 1% to 15% according to some studies [11]. This third canal may be independent with an individual foramen or may connect to the apical region with the mesiovestibular or mesiolingual canals. Another very common anatomic variation on these molars is the presence of an isthmus on the mesial root, a narrow slit between the buccal and lingual canals of this root, which makes access of the endodontic instruments and auxiliary chemical substances more difficult and maintains microorganisms and residual tissues in this region. The prevalence of an isthmus on the mesial root of first mandibular molars varies from 54% to 89%, and they are localized mainly on medium and apical thirds of the root. There are many recent reports in the literature of notable anatomic variations in third molars, first maxillary molars and second mandibular premolars however, few recent reports have shown cases of treatment of mandibular permanent first molars with

five canals, with three in the mesial root, as in the current thought of Endodontics. Regarding the high incidence of anatomic variations, with the presence of additional root canals and isthmus in these teeth, the importance of an appropriate treatment is critical for successful outcomes in these cases. Thus, this paper aims to report and describe the successful endodontic treatment of a mandibular first molar presenting five root canals.

Possible Variations in Mandibular First Molars

Radix Entomolaris/ Paramolaris

In 2004, De Moor et all presented case reports of a supernumerary root present in the disto lingual aspect of mandibular first molars [4].

The primary aim of endodontic treatment is the elimination of bacteria from the infected root canal and the prevention of subsequent reinfection. This is primarily established by ensuring that proper cleaning and shaping is done followed by proper three dimensional obturation done with a tight coronal and apical seal. Establishing adequate access for cleaning and shaping is an integral part of this procedure. In order to achieve these endodontic objectives, the dental practitioner must be well versed in the knowledge of the anatomy of the tooth, crown, root and root canals and the various possible morphologies and pathologies and how to treat it.

Several authors have reported about the morphology of the mandibular first molars. Most articles have shown that the permanent mandibular first molar usually has three to four root canals present, usually two in the mesial root and one or two in the distal root. Along with the number of root canals, the number of roots may also vary. The majority of first and second mandibular molars are two rooted with two mesial and one distal canals. A major variation occurs when sometime the permanent mandibular first molar has a presence of an extra third root which increases the chances of various morphological appearances in the root canal system. This has a frequency of less than 5% in white Caucasian, African, Eurasian and Indian populations.

For successful endodontic diagnosis and treatment, the dental practitioner must employ proper radiographic techniques to understand the complete root canal anatomy of the tooth to be treated. Radiographs taken at different angulations reveal the basic information regarding the anatomy of a tooth and can thus help to detect any aberrant anatomy such as extra canals / roots. However, a significant constraint in conventional radiography is that it produces a two-

dimensional image of a three-dimensional object, resulting in the superimposition of the overlying structure. To achieve a more detailed understanding of the morphological structure of root canals and their interrelations, more advanced diagnostic tools are required.

The most effective tool in diagnosis of the endodontic system has proven to be the Cone beam computed tomography or CBCT. It is an imaging method employing tomography to generate a three-dimensional reconstruction of the entire tooth at different levels from a single imaging procedure. The advantages of CBCT imaging are that it completely eliminates the superimposition of structural images outside the area of interest and provides a high-contrast resolution and data from a single computed tomography imaging process. Moreover, the images can be viewed in a coronal, sagittal, or even an oblique or curved image planes—a process referred to as multiplanar Reformation (MPR).

RE has an occurrence of less than 5% in the Indian population, and such cases are rarely observed during routine endodontic procedures. We report on six such cases in this paper. RE was observed in the mandibular first molars of three patients being root canal treated. This anatomy was also present on three extracted mandibular teeth which were studied in detail to gain an understanding of their morphological characteristics. Knowledge of such variations can be beneficial in delivering treatment to patients presenting with related diversities in their root canal anatomy[33].

The exact cause of radix entomolaris is still not known. Some authors say that it may be due to disturbance during odontogenesis or may be due to an atavistic origin.

In 35% of cases, four canals are present[6,7]. The distal root contains two canals, one in the buccal and the other in the lingual position. The second distal canal is sometimes found in a separate root in the disto lingual position. It is slightly smaller and mesial to the distobuccal root [9].

Apart from Vertucci’s classification of root canal anatomy variations in mandibular molars, another variation of these teeth is the presence of an extra root. The three roots permanent mandibular first molars are usually present on the distal root and is called as Radix Entomolaris. The prevalence of these three-rooted mandibular first molars appears to be less than 3% in African populations, not to exceed 4.2% in Caucasians, to be less than 5% in Eurasian and Asian populations, and to be higher than 5% (even up to 40%) in populations with Mongolian traits. A total of 18 cases, (12 root filled and six extracted mandibular first molars) with an RE were collected during the years 2000–2003 in patients of Caucasian origin. As far as the access was concerned, entering the root canal in this tooth required a

modification the opening in a disto lingual direction resulting in a trapezoidal opening cavity [4].

C - Shaped Canal

The C-shaped canal was first documented in endodontic literature by Cooke and Cox in 1979,[21] is so named for the cross-sectional morphology of the root and root canal. Instead of having several discrete orifices the pulp chamber of the C-shaped canal is a single ribbon-shaped orifice, which in mandibular molars starts at the mesiolingual line angle and sweeps around the buccal to end at the distal aspect of the pulp chamber[22].

Typically, this canal configuration is found in the teeth with fusion of the roots either on its buccal or lingual aspect. In teeth with this anatomical configuration the pulpal floor is usually situation in a deeper portion and the shape curvature of the canal orifice is unusual. The main anatomic feature of C-shaped canals is the presence of a fin or web connecting the individual canals.

Investigations of root development in mouse molars showed that roots were formed by the meeting of dentine leaflets. The fusing of these leaflets was sometimes irregular, forming accessory canals and occasionally, especially in the third molars the leaflets failed to form. In the case of mandibular molars such failure of dentine leaflet formation resulted in a C-shaped root canal. Once recognized the C-shaped canal provides a challenge with respect to debridement and obturation, especially because it is unclear whether the C-shaped orifice found on the floor of the pulp chamber follows up to the root portion in the apical third. Fused and C-shaped roots may present with narrow grooves that predispose to localized periodontal disease which may in fact be the first diagnostic indication of such anatomic variation. This type of canal configuration is often seen in teeth with fused roots. In such teeth, the floor of the pulp chamber is usually situated deeply and may assume an unusual anatomic appearance[23].

Once it is recognised a tooth with a C shaped canal, it is difficult to establish whether or not the working length of that canal reaches till the apical third of the root or whether it terminates much before[26]. Fused and C-shaped roots may present with narrow grooves that predispose to localized periodontal disease which may in fact be the first diagnostic indication of such anatomic variation[27].

C shaped canal anatomy is a challenge during the preparation and obturation phase and is definitely to be dealt with in a careful manner to prevent any endodontic mishaps. In order to

completely successfully treat the affected tooth one must be follow a strict protocol while attempting this root canal treatment.

For the successful treatment of such C-shape canals following points should be taken into consideration.

Radio graphically it may present as a single fused root or as two distinct roots. Cooke and Cox stated that it is impossible to diagnose C–shaped canals on the radiographs. Radiographs taken while probing the root canal system reveal two characteristics: Instruments tend to converge at the apex; instruments appear clinically and radiographically to perforate the furcation[28].

After routine access cavity preparation and removal of pulp tissue the orifice portions of the slit must be widened considerably early in treatment but not too deeply toward the apex[31].

In C shaped root canal systems generally the mesiolingual canal is fairly distinct from the apical third of the root portion, although it may be significantly shorter than mesiobuccal or distal canals. The mesiobuccal canal may merge with distal canal and both exit through a single foramen or both canal have separate portals of exit [32].

Middle Mesial Canal

Sometimes, the “extra” canal is found in the mesial root, which therefore contains three canals. This is the middle mesial canal [8-16].

Results of the clinical study of 760 first mandibular molars, showed that 20 (2.6%) had three canals in the mesial root. Of these 20 teeth, 13 (65%) had an intermediate canal which joined the mesiobuccal canal in the apical third, 6 (30%) joined the mesiolingual canal in the same location. In only one case did the intermediate or third canal retain its individual nature and end in an independent foramen [13]. The presence of this third canal present in the mesial root is uncommon root morphology and therefore a significant consideration during root canal treatment of such teeth.

The probability of occurrence of middle mesial canal in mandibular first molars ranges from 1% [17] to 15% [18]. Radiographically the number and configuration of root canal system was found to show that on 60 teeth revealed one canal in the mesial root in 5 percent, two in 78.3 percent, three in 13.3 percent and four in 3.3 percent [18].

Aminsobhani M reported 21 cases of mandibular first molar with three mesial canals [19]. Faramarzi F reported a case of mandibular first molar with three mesial canals and broken instrument removal[20].

In many of these cases identification of the middle mesial canal lead to successful endodontic treatment of the decayed tooth. In many cases, failure to locate the canal results in the usual consequences of poor endodontic treatment. In order to ensure proper location of these intermediate canals in the mesial root Fabra H Campos has suggested the following steps: [12,13]

- After preparation of the access cavity the dentinal elevation which is present between the entrance of the mesiobuccal and mesiolingual canals are removed with the help of ultrasonic tips or burs.
- An explorer is used to explore through the groove connecting the mesiobuccal and mesiolingual canal to search for any possible intermediate depression. Also in teeth with vital pulp a bleeding spot can be observed which may indicate MMC (middle mesial canal).
- Catheterise the third canal by using a thin file (#08 or 10) in an alternating 45 degree rotating motion.
- Once the canal is located enlarge canal entrance. Usually this canal may join with the middle third or the apical third with either the mesiolingual or mesiobuccal canal, ending in one foramen.

Taurodontism

Witkop defined taurodontism as "teeth with large pulp chamber in which the bifurcation or trifurcation are displaced apically, so that the chamber has greater apicao-occlusal height than in normal teeth and lacks the constriction at the level of the cementoenamel junction[34]. The term taurodontism was coined by Sir Arthur Keith to describe the "bull-like" condition in teeth in which the tall root trunk encloses a high pulp chamber and short roots [35]. The etiology of taurodontism is unclear. It is thought to be caused by the failure of Hertwig's epithelial sheath diaphragm to invaginate at the proper horizontal level, resulting in a tooth with short roots, elongated body, an enlarged pulp, and normal dentin. Previously, taurodontism was related to syndromes such as Down's and Klinefelter's. Today, it is considered as an anatomic variance that could occur in a normal population regardless of whether any pathology is associated with it [36].A taurodont does not show any significant morphological characteristics that helps in its identification. The radiographic examination is

the only way to visualize a rectangular configuration of the pulp chamber. The apico-occlusal height of the pulp chamber varies depending upon the type of taurodontism [37]. Shaw has classified taurodontism into hypo, meso, and hyper taurodontism on the basis of the apical displacement of the floor of the pulp chamber[38].The teeth most frequently affected are the molars diagnosed most easily by radiograph. Premolars present a lower incidence and the mandibular teeth are found to be more commonly affected [39-42].

Conclusion

The mandibular first molar is the most common tooth to be advised for root canal treatment. In order to successful treat these teeth, proper knowledge of the variations in root canal anatomy is necessary. To successfully identify the root canal anatomy of the tooth to be treated, modern methods of radiography should be considered to ensure all possible variations. The mandibular molar is the first permanent molar to erupt into the oral cavity and it is most often tooth requiring endodontic therapy. The knowledge of root canal system and the most common variations should be kept in mind before starting root canal therapy. With the recent innovations of various operating aids, the coming era can witness more variations in the root canal morphology of permanent mandibular first molar.

Abstract

The purpose of this review is to evaluate the effects of ketamine in depressed patients which makes it a valuable research tool to identify the response and develop the next generation of fast-acting antidepressants.A growing body of preclinical research suggests that brain glutamate systems may be involved in the pathophysiology of major depression and the mechanism of action of antidepressants. The review aims to assess the treatment effects of a single dose of an N-methyl-d-aspartate (NMDA) receptor antagonist in patients with depression. The N-methyl-D-aspartate (NMDA) antagonist ketamine,an fast acting antidepressants has consistently shown antidepressant effects within a few hours of its administration.The ketamine can exert their antidepressant effects within hours or a few days of their administration.It is a better understanding of the presumed mechanisms associated with these rapid antidepressant effects.

Keywords*: Antidepressant, ketamine, N-methyl-D-aspartate, memory, depression.*

Introduction

Newer antidepressants are essential for the individuals with major depressive disorder (MDD) that does not respond adequately to treatment and because of a delay that appear before the emergence of therapeutic effects. Recent evidence from clinical studies reveals that the NMDA antagonist ketamine is a revolutionary antidepressant because it acts rapidly and is effective for treatment-resistant patients. A single infusion of ketamine stimulates depressive symptoms in treatment-resistant depressed patients within hours and these effects may lastsfor up to 2 weeks(1).Although the discovery of ketamine's effects has reshaped drug discovery for antidepressants, the psychotomimetic properties of this compound limit the use of this therapy to the most severely ill patients.

Major depressive disorder (MDD) is a serious public health problem and one of the most common psychiatric disorders, with a lifetime prevalence of 17% in the United States(1).The currently available antidepressants provide a measurable degree of therapy. 50% of MDD patients do not respond to first–line treatment with conventional antidepressants(2). Moreover, the 3–4 week delay in the onset of therapeutic efficacy leads the patients to suicidal ideation(3).

Recent clinical trials shows that the NMDA antagonist ketamine is a revolutionary novel antidepressant because it acts rapidly and is effective for treatment-resistant patients. Ketamine is a non-competitive antagonist acting at NMDA glutamate receptor. Unlike, classical antidepressants whose therapeutic effects takes weeks to be observed , an acute intravenous injection of ketamine is sufficient to induce quick and long lasting antidepressant effects upto two weeks(4,5). The purpose of this review is to evaluate the effects of ketamine in depressed patients which makes it a valuable research tool to identify the response and develop the next generation of fast-acting antidepressants.A growing body of preclinical research suggests that brain glutamate systems may be involved in the pathophysiology of major depression and the mechanism of action of antidepressants. The review aims to assess the treatment effects of a single dose of an N-methyl-d-aspartate (NMDA) receptor antagonist in patients with depression.

What is Ketamine?

Ketamine is a medication that is used to induce loss of consciousness, or anesthesia. It can produce relaxation and relieve pain in humans and animals. Ketamine belongs to a group of

drugs known as dissociative anesthetics. It is also known as Ketalar, Ketanest, and Ketaset.Other drugs in this category include the hallucinogen, phencyclidine (PCP), dextromethorphan (DXM), and nitrous oxide, or laughing gas.These types of drugs makes a person feel detached from sensations and surroundings, as if they are floating outside their body.It induces a trance like state while providing pain relief, sedation, and memory loss.Heart function, breathing and airway reflexes generally remain functional(6).

Ketamine is an NMDA receptor antagonist with a potent anesthetic effect.It was developed in 1963 as a replacement for phencyclidine (PCP).It started being used for veterinary purposes in Belgium and in 1964 was proven that compared to PCP, it produced minor hallucinogenic effects and shorter psychotomimetic effects. It was FDA approved in 1970, and from there, it has been used as an anesthetic for children or patients undergoing minor surgeries but mainly for veterinary purpose(7).

It is a class III scheduled drug and is approved for use in hospitals and other medical settings as an anesthetic.However, it is also a commonly abused "recreational" drug, due to its hallucinogenic, tranquillising and dissociative effects. Ketamine is safe to use in controlled, medical practice, but it has abuse potential(8). Used outside the approved limits, its adverse mental and physical health effects can be hazardous. Prolonged use can lead to tolerance and psychological addiction.

Structure

In chemical structure, ketamine is an arylcyclohexylamine derivative. Ketamine is a chiral compound. Most pharmaceutical preparations of ketamine are racemic; however, some brands reportedly have (mostly undocumented) differences in their enantiomeric proportions. The more active enantiomer, (S)-ketamine, is also available for medical use under the brand name KetanestS(9).

Indications- (10)

- Debridement, painful dressings, and skin grafting in burn patients, as well as other superficial surgical procedures.
- Neurodiagnostic procedures such as pneumonencephalograms, ventriculograms, myelograms, and lumbar punctures.
- Diagnostic and operative procedures of the eye, ear, nose and mouth, including dental extractions.
- Diagnostic and operative procedures of the pharynx, larynx, or bronchial tree. NOTE: Muscle relaxants, with proper attention to respiration, may be required.
- Sigmoidoscopy and minor surgery of the anus and rectum, and circumcision.
- Extra peritoneal procedures used in gynaecology such as dilatation and curettage.
- Orthopaedic procedures such as closed reductions, manipulations, femoral pinning, amputations, and biopsies.
- As an anesthetic in poor-risk patients with depression of vital functions.
- In procedures where the intramuscular route of administration is preferred.
- In cardiac catheterisation procedures.

Methods of Use

Ketamine is used as an anesthetic due to the hallucinations it may cause.

Since it suppresses breathing much less than most other available anaesthetics.It is the drug of choice for people in traumatic shock who are at risk of hypotension.Low blood pressure is harmful in people with severe head injuryand ketamine is least likely to cause low blood pressure, often even able to prevent it(11,12). The effect of ketamine on the respiratory and circulatory systems is different from that of other anestheticsKetamine is used as a bronchodilator in the treatment of severe asthma(13). Low doses of ketamine reduces morphine use and nausea and vomiting after surgery(14).High quality evidence in acute pain is insufficient to determine if ketamine is useful in this situation(15).

Low-dose ketamine is sometimes used in the treatment of complex regional pain syndrome (CRPS)(16). Ketamine has been tested in treatment-resistant bipolar depression, major depressive disorder, and people in a suicidal crisis in emergency rooms(17).

Administration

The drug is given by a single intravenous infusion at doses less than those used in anesthesia, and preliminary data have indicated it produces a rapid (within 2 hours) and relatively sustained (about 1–2 weeks long) significant reduction in symptoms in some patient (18).Initial studies with ketamine have revealed scientific and clinical interest due to its rapid onset, and because it works by blocking NMDA receptors for glutamate, a different mechanism from most modern antidepressants that operate on other target(19).

Physical Effects

The effects of ketamine are considered as dose dependent. The lower doses of drugs produces varying results when compared to higher doses. A dose of 1-2mg / kg of body weight produces an intense experience lasting about one hour . The effects include a sense of hallucinations, floating and dissociation and stimulation. Larger doses of ketamine may produce "K - hole " , which is likened to an out-of-body or near death experience . Higher doses of ketamine may result in severe respiratory depression , muscle twitches, dizziness,slurred speech , nausea and vomiting (20).One of the most dangerous effects of ketamine is the helpless and confused state of the user after the infusion of the drug . They difficulty with balance , combined with numbness, muscle weakness, and impaired vision.

However, its emergence as a club drug differs from other club drugs (e.g. MDMA) due to its anesthetic properties (e.g., slurred speech, immobilization) at higher doses(21);in addition, there are reports of ketamine being sold as "ecstasy"(22).and also as part of a "postclubbingexperience".Related to its ability to cause confusion and amnesiac effects, ketamine can leave users vulnerable to date rape(23).

Side Effects

Side effects may include one or more of the following (24)

- Cardiovascular: abnormal heart rhythms, slow heart rate or fast heart rate, high blood pressure or low blood pressure.

- Central nervous system: Ketamine is traditionally avoided in people with or at risk of intracranial hypertension (ICP) due to concerns about ketamine causing increased intracranial pressure.
- Dermatologic: Transient erythema, transient morbilliform rash
- Gastrointestinal: Anorexia, nausea, increased salivation, vomiting
- Local: Pain or exanthema of the injection site
- Neuromuscular and skeletal: Increased skeletal muscle tone (tonic-clonic movements)
- Ocular: Double vision, increased intraocular pressure, nystagmus
- Respiratory: Airway obstruction, apnea, increased bronchial secretions, respiratory depression, laryngospasm

These reactions are less common in patients less than 15 years old and greater than 65 years old and when administered intramuscularly.

Conclusions

The development of ketamine for the treatment of depression is an interesting area of investigation which offers a good therapeutic approach. Further, the rapid antidepressant action of ketamine gives us belief that serious depressive episodes may be rapidly eliminated rather than waiting for weeks and months. The development of these therapeutic agents require careful examination of their tolerability and adverse effects. This makes it evident that ketamine may be a viable option for treatment of depressed persons.

Abstract

Much attention has been focused on the activity of the naturalantioxidants present in fruits and vegetables, because fruits and vegetable consumption is inversely related to the incidence of heart disease and several cancers. Berries contain powerful antioxidants, potential allergens, and other bioactive compounds. Berries contain micronutrients such as vitamin C and folic acid which are essential for health. They may also have additional health benefits as they are also rich in phytochemicals such as anthocyanins and flavonoids, which are responsible for their red, violet, purple and blue colours. Experimental data has lead to numerous health claims implying that they may protect humans against heart disease, cancers and ageing. This review gives an insight about the flavonoids and the antioxidant properties present infew berries, due to flavanoids, which we consume in daily life like strawberries, blueberries, raspberries, gooseberries and blackberries.

KeyWords*:Anthocyanin, AntioxidantActivity,Berries,Flavonoids, PhenolicCompounds.*

Introduction

A major contributing factor to the aetiology of chronic diseases is a poor diet. Diet in the developed world is a complex mixture of foods with highly variable consumption patterns [1]. Berries are important dietary sources of fibre and essential vitamins and minerals. They also contain a vast number of other phytochemicals that have shown marked bioactivities in mammalian cells like oxidative damage, detoxification enzymes, the immune system, blood pressure, platelet aggregation, and anti-inflammatory, antibacterial activities [2]. Berries can also be significant dietary sources of folic acid, a water soluble B vitamin and also may play a role in reducing risk of heart disease and cancer through a range of mechanisms including lowering homocysteine levels, catalysing nitric oxide formation and maintaining DNA stability[3]. In particular, many types of berries contain a high level of vitamin C (ascorbic acid) andphenolic compounds which provide the distinctive and vibrant palate of colours found in dark berries. The most commonly consumed berries are strawberries(Fragariax ananassa), raspberries (Rubusidaeus), blackberries (Rubusspp.), blueberries (Vacciniumcorymbosum), black currants (Ribesnigrum) and red currants (Ribesrubrum). Natural antioxidants present in foods and other biological materials have attracted considerable interest because of their presumed safety and potential nutritional and therapeutic effects. The increasing level of interests in the search for natural replacements of synthetic antioxidants has paved way for evaluation of large number of antioxidant from plant sources [4]. The most current research on antioxidant action focuses on phenolic compounds such as flavonoids and anthocyanins.

PhenolicCompounds

Phenolic compounds are considered as a significant part of the human diet, and are of huge interest in the research field due to their antioxidant properties. Phenolic compounds consists an aromatic ring containing one or more hydroxyl groups. Generally,structures ofphenolic compounds vary from that of a simple phenolic molecule to that of a complex high weight molecular polymer. The antioxidant activity of phenolic compounds depends on the structure, mostly, the number and positions of the hydroxyl groups and the nature of substitutions on the aromatic rings. Phenolic compounds are secondary metabolites which are derivatives of the pentose phosphate, and phenyl propanoid pathways in plants [5]. Phenolic compounds play an important role in growth and reproduction and also provides protection against pathogens and predators, besides contributing towards the colour and sensory characteristics

of fruits and vegetables. Phenolic compounds exhibit a wide range of physiological properties, such as anti-allergenic, antiartherogenic, antiinflammatory, antimicrobial, antioxidant, anti-thromboticand vasodilator effects.

Flavonoids

Flavonoids constitute the largest group of plant phenolics, accounting for more than half of the eight thousand naturally occurring phenolic compounds, many of which are responsible for the bright colors of flowers, fruit, and leaves. Flavonoids are low molecular weight compounds, consisting of fifteen carbon atoms, arranged in a C6–C3–C6 configuration [6], which are labeled A, B, and C (Fig 1). The various classes of flavonoids differ in the level of oxidation and pattern of substitution of the C ring. Individual compounds within a class differ in the pattern of substitution of the A and B rings. Few of the phenolic compounds are flavones, flavanones, isoflavones, flavonols, flavanonols, flavan-3-ols, anthocyanidins, biflavones, chalcones, aurones, coumarins, hydrolyzable tannins, proanthocyanidins (flavan-3-ol oligomers), caffeates, and lignans, which are all plant phenols. Flavonoids generally occur in plants as glycosylated derivatives.Apart from various vegetables and fruits, flavonoids are found in seeds, nuts, grains, spices, and different medicinal plants as well in beverages, such as red wine, tea, and beer. The flavones apigenin and luteolin are common in cereal grains and aromatic herbs such as parsley, rosemary, thyme, while their hydrogenated analogues hesperetin and naringin are almost exclusively present in citrus fruits. The flavonols, quercetin and kaempferol are predominant in vegetables and fruits, where they are found mainly in the skin, with the exception of onions. Isoflavones are found in legumes, including soybeans, black beans, green beans, and chick peas. Alfalfa and clover sprouts and sunflower seeds also contain isoflavones. The flavan-3-ols, catechin, epicatechin, epigallocatechin, and their gallate esters are widely distributed in plants, although they are very rich in tea leaves. Flavan oligomers are present in apples, grapes, berries, persimmon, black currant, sorghum and barley grains. Anthocyanidins and their glycosides, namely, anthocyanins are natural pigments and are abundant in berries and red grapes. Flavonoids play different roles in the ecology of plants. Due to their contribution in producing attractive colors, flavones, flavonols, and anthocyanidins may act as visual signals for pollinating insects. Flavonoids act as catalysts in the light phase of photosynthesis and as regulators of iron channels involved in phosphorylation.A significant role of flavonoids is the scavenging of oxygen-derived free radicals. In vitro experimental systems also showed that flavonoids

possess anti-inflammatory, anti-allergic, anti-viral, and anti-carcinogenicproperties. Apart from their physiological roles in the plants, flavonoids are important components in the human diet, although they are considered as non-nutrients

. The level of intake of flavonoids is high as compared to those of vitamin C, vitamin E and Vitamin A. Flavonoids intake can range between 50 and 800 mg per day, depending on the consumption of vegetables and fruits, and of specific beverages, such asred wine, tea, and unfiltered beer [7]. Thus,variations in consumption of these foods and beverages are mainlyresponsible for the overall flavonoid intake in variousnational diets.

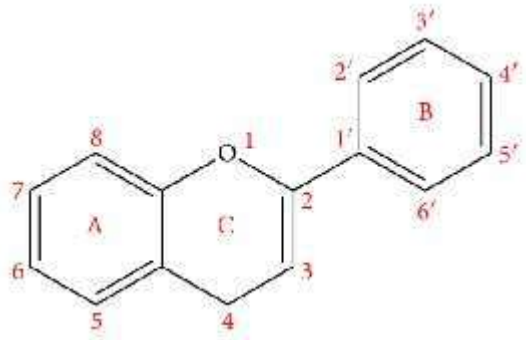

Figure1: Basic structure of flavonids

ClinicalEffects

The different clinical effects of flavonoids are discussed in detail below.

Anti-OxidativeEffects

The best-described property of almost every group of flavonoids is their capacity to act as antioxidants. The flavones and catechins seem to be the most powerful flavonoids for protecting the bodyagainst reactive oxygen species. Body cells and tissues are continuouslyunder threat caused by the damage by free radicals and reactiveoxygen species, which are produced during oxygenmetabolism or are induced by exogenous damage [8, 9]. The mechanismsand the sequence of events by which free radicals interferewith cellular functions are not fully understood, but one of the mostimportant events seems to be lipid peroxidation, which results incellular membrane damage. This cellular damage causes a shift inthe net charge of the cell, changing the osmotic pressure, leading to swelling and eventually cell death. Free radicals can attract variousinflammatory mediators, contributing to a general inflammatory response and tissue damage. To protect themselves from reactive oxygen species, living organisms have developed several effectivemechanisms [10]. The antioxidant-

defense mechanisms of thebody include enzymes such as superoxide dismutase, catalase, andglutatione peroxidase, but also nonenzymatic counterparts such asglutathione, ascorbic acid, and alpha-tocopherol. The increased productionof reactive oxygen species during injury results in consumptionand depletion of the endogenous scavenging compounds.Flavonoids may have an additive effect to the endogenous scavengingcompounds. Flavonoids can interfere with more than three different freeradical producing systems.

Anti-AtherosclerоticEffects

Because of their antioxidative properties, flavonoids are likelyto have a major influence on the vascular system. Oxygen radicalscan oxidize LDL, which tends to injure the endothelial wall and therebypromotes atherosclerotic changes. A study reported that the flavonoids present in regularly consumed foods might reduce the risk of morbidity from coronary heart disease in elderly men [11]. A Japanese studyreported an inverse correlation between flavonoid intake and totalplasma cholesterol concentrations [12]. Oxidative stress and vascular damage are implied to play a significant role in dementia, andregular intake of flavanoids through berries and red wine is reported to prevent the development ofdementia [13].

Anti-InflammatoryEffects

Cyclooxygenase and lipoxygenase play a vital role asinflammatory mediators. They are involved in the release of arachidonic acid, which is a precursor for a general inflammatory response. Neutrophils containing lipoxygenase can create chemotacticcompounds from arachidonic acid, which provoke the release of cytokines. Selected phenolic compounds were shown to inhibit both the cyclooxygenase and 5-lipoxygenase pathways. This inhibition reduces the release of arachidonic acid [14]. The exact mechanism by which flavonoids inhibit these enzymes is not clear. Quercetin, in particular, inhibits bothcyclooxygenase and lipoxygenase activities, thus diminishing the formation of these inflammatory metabolites [15].Another anti-inflammatory feature of the falvonoids, isto inhibit eicosanoid biosynthesis [16]. Flavonoids also has the ability to inhibit both cytosolic andmembranal tyrosine kinase. Integral membrane proteins,such as tyrosine 3-monooxygenase kinase, are involved in a varietyof functions, such as enzyme catalysis, transport acrossmembranes, transduction of signals that function as receptors ofhormones and growth factors, and energy transfer in ATP synthesis.Inhibition of these proteins results in inhibition of uncontrolledcell growth and

proliferation. Tyrosine kinase substratesseem to play key roles in the signal transduction pathway thatregulates cell proliferation. Another significant anti-inflammatory propertyof flavonoids is their ability to inhibit neutrophildegranulation, which is a direct way to diminish the release ofarachidonic acid by neutrophils and other immune cells [17].

Anti-TumorEffects

The antitumor activity of flavonoids is still a point of discussion.Antioxidant systems are frequently inadequate, and damagefrom reactive oxygen species is proposed to be involved in carcinogenesis [18]. Reactive oxygen species can damage DNA,and division of cells with unrepaired or unrepaired damageleads to mutations. If these changes appear in critical genes, suchas oncogenes or tumor suppressor genes, initiation or progressionmay result. Reactive oxygen species can interfere directly with cell signaling and growth. The cellular damage caused by reactive oxygen species can induce mitosis, increasing the risk that damaged DNA will lead to mutations, and can increase theexposure of DNA to mutagens.A studyhas stated that flavonoids, as powerful antioxidants, can inhibitcarcinogenesis. Some flavonoids, such as fisetin, apigenin, and luteolin are stated to be potent inhibitors of rapid cell proliferation [19]. Quercetin and apigenin inhibited melanoma growth and influenced the invasive and metastatic potential in mice [20]. This finding may offer new insights about possible therapies for metastatic disease.

Anti-AngiogeneticEffect

It has been implied that flavonoids has an ability to inhibit angiogenesis. Angiogenesis is a strictly controlled process in the human body. The process of angiogenesis is regulated by a variety of endogenous angiogenic and angiostatic factors. In contrast, pathologic, unregulated angiogenesis occurs in cancer [21]. Angiogenesis inhibitors can interfere with various steps in angiogenesis, such as the proliferation and migration of endothelial cells and lumen formation [22]. The mechanism behind the antiangiogenic effect of flavonoids is still unclear. A possible mechanism could be inhibition of protein kinases [23].

AntiThrombogenicEffects

Platelet aggregation plays a vital role in the development of atherosclerosis and acute platelet thrombus formation, which results in embolization of stenosed arteries. Activated platelets adhering to vascular endothelium, results in generation of lipid peroxides and oxygen free radicals, which in turn inhibit the endothelial formation of prostacyclin and nitrous oxide. Few flavonoids, suchas quercetin, kaempferol, and myricetin were shown to be effective inhibitors of platelet aggregation in dogs and monkeys [24]. Flavonols are particularly antithrombotic because they have the ability to directly scavenge free radicals, thereby maintaining proper concentrations of endothelial prostacyclin and nitric oxide [25]. It is well known that arachidonic acid, which is released in inflammatoryconditions, is metabolized by platelets to form prostaglandin, endoperoxides, and thromboxane A2, leading to platelet activation and aggregation [26]. The vital antiaggregatory effect of flavonoids is inhibition of thromboxane A2formation. Flavonoids affect arachidonic acid metabolism in various ways [27]. Invitro studies showed that flavonoids bind to platelet membranes and may therefore have an accumulative effect over period of time [28].

Anti-ViralEffects

Some of the viruses reported to be affected by flavonoids are herpes simplex virus, respiratory syncytial virus, parainfluenza virus, and adenovirus. Quercetin was stated to exhibit both anti-infective and anti-replicative abilities. The interaction of flavonoids with the different stages in the replication cycle of viruses was previously described [29]. There is some evidence that flavonoids in their glycone form seem to be more inhibitory on rotavirus infectivity than are flavonoids in their aglycone form [30]. Since the worldwide spread of HIV since the 1980s, investigations of the antiviral activity of flavonoids have been mainly focused. The discovery and development of flavonoids as anti-HIV agents has largely expanded in the past two decades. Most of these studies focused on the inhibitory activity of reverse transcriptase, or RNA-directed DNA polymerase [31], but anti integrase and anti-protease activities were also described. Flavonoids have mainly been studied in in vitro experiments, therefore, no clear confirmation of contribution of flavonoids to the treatment of HIV-infected patients has yet been shown [32].

The Berry Family

Blueberry

Blueberries are perennial flowering plants that are usually erect. The flowers are bell-shaped, white, pale pink or red, sometimes tinged greenish. The fruit is considerably small in diameter with a flared crown at the end. They are pale greenish at first, then reddish-purple, and indigo coloured when ripe.They are most commonly found in Europe, Asia, United States, Canada and in Southern Hemisphere.Blueberries are good sources of phenolic acids, principally chlorogenic acid and flavonoids like anthocyanin. They contain the highestantioxidant activityamong the berries [33]. Crude extracts of phenolics, extracted using ethanol as a solvent, from wild blueberry leaves exhibited strong antioxidant properties [34].

Strawberry

The strawberries are first cultivated in France during the late 18^{th} century. They are generally grown in European countries. The fruit is known for its characteristic aroma, bright red colour and juicy texture. It is consumed either fresh or in prepared foods such as preserves, fruit juice, pies, ice creams, milkshakes, and chocolates. Artificial strawberry aroma is also widely used in many industrialised food products.Several studies have shown that the strawberry generally possesses a high level of antioxidant activity, which is linked to the levels of phenolic compounds in the fruit [35, 36, 37]. Wang and Jiao [38]showed that strawberry juice extracts exhibited a high level of antioxidant capacity against free radical species including superoxide radicals, hydrogen peroxide,hydroxyl radicals, and singlet oxygen. Strawberry is one of the most commonly consumed berries. They are an important dietary source of fibre and bioactive compounds, micronutrients and phytochemicals, which are responsible for their bright colour. In particular, strawberries are rich in vitamin C, a handful of strawberries is sufficient to cover the vitamin C recommended daily allowance (RDA) and are among the richest natural food sources of folate [39].Anthocyanins are the most abundant type of polyphenols in strawberry.

Raspberry

The raspberries are perineal plants belonging to a plant species in the genus *Rubus* of the rose family. Raspberries are widely grown in all temperate regions of the World. They are one among the fruits containingthe highest antioxidant levels. The antioxidant activity of raspberries is primarily due to high levels of vitamin C,anthocyanins and ellagitannins. Anthocyaninsare red pigment polyphenols that have been implicated in protection against

coronary heart disease and certain types of cancer [40]. Ellagitanninshave been identified in tea, many medicinal plants, and several fruits, including raspberries.Ellagitannins have been described to have general antioxidant effects and vasorelaxation properties [41, 42]. Raspberry could therefore be considered as a fruit source of variety of potentially healthy compounds.

Gooseberry

The gooseberry is straggling bush with bell shaped flowers. It is commonly found in Europe, north western Africa and Southeast Asia.The fruit has a good source of provitamin A, minerals, vitamin C and vitamin B-complex. The fruit contains high level of fructose, which makes it valuable for diabetics. Its high content of phosphorus levels and dietary fibre is of importance, wherein fruit pectin acts asan intestinal regulator [43].

Blackberry

Blackberry is a perennial shrub with sprawling, woody, and thorny stems. They can reach the height of about 5 meters. It has dark green hairy leaves and flowers are white to pale pink. Fruits are the well-known fleshy black berries. The plant materials contain various type of phytochemical such as alkaloids, flavonoids, tannins, saponins, glycosides, terpenoids, sterols, and carbohydrates. Blackberries are known for their anticancer properties. As they contain antioxidants, they are known to destroy the free radicals that harm cells and can lead to cancer. They also help to protect and strengthen the immunity. Blackberries are also used to make wine, brandy, and flavour liqueurs and cordials and also used as a long-standing home remedy for anaemia, regulates menses, diarrhoea, and dysentery [44].

Conclusion

The study of flavonoids is complex because of the heterogeneity of the different molecular structures and the scarcity of data on bioavailability. Furthermore, insufficient methods are available to measure oxidative damage in vivo and the measurement of objective endpoints remains difficult. While the use of flavanoids as food antioxidants is particularly interesting, practical aspects that need to be considered include extraction efficiency, availability of sufficient raw material, and toxicity or safety considerations.Consuming a diet rich in

antioxidants can improve your health, protect your skin and hair and prevent certain diseases.Antioxidants play a vital role in neutralising harmful by-products of metabolism, free radicals that can lead to cancer and age related diseases. Berries are considered to be the best sources among all the fruits and vegetables containing antioxidants. Berries may reduce the build-up of bad cholesterol that contributes to cardiovascular disease and stroke. It is more effective to get antioxidants through natural diet, as opposed to taking supplements.

Aphthous Ulcer – A Review

Sarah Banu[1], Mahesh Ramakrishnan[2]

Graduate Student[1], Reader[2], Department Of Pedodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Mouth ulcer is a very common and painful condition, which is categorized as aphthous stomatitis. It is most commonly seen in early childhood and adolescence. These ulcers are small round with circumscribed margins with yellow floor. They are pearl coloured flakes in the mouth or inside the lips. These are oral mucosal lesions and these ulcers are commonly called as Recurrent Aphthous Stomatitis (RAS). There are also different types of ulcers like minor ulcers which are not very large in size and heal within 7-14 days, major ulcers heal slowly which can extend up to weeks or months and the third one is herpetiform ulcer which is multiple pinpoint ulcers that heal within a month. Some reason for the occurrence of ulcers could be stress, trauma, stopping smoking, menstruation and food allergy. Sometimes it could also be due to deficiency of iron, vitamin B12. In children aphthae occurs also due to periodic or high fever, pharyngitis and cervical adenitis.

Key Words: *Aphthous ulcer, minor ulcer, major ulcer, herpetiform*

Introduction

Aphthous ulcer is also called as recurrent aphthous stomatitis or canker sores. It is usually indicated by a redness and swelling or white colour lesion. It is also associated with bleeding in adverse conditions. Severe aphthous ulcer can lead to difficulty in eating [1]. There can be several reasons for the occurrence of aphthous ulcer like stress, nutritional deficiency, genetic and hormonal disturbances [1-3]. These painful lesions usually occur at irregular intervals but have the same sequence of events in every cycle [4]. There are three types of aphthous ulcer such as minor, major and herpetiform. The most common of all is the minor ulcer with an approximate of 80-85% of population [5-8]. The exact etiology and pathophysiology of aphthous ulcer is not yet discovered [9]. Use of tobacco can be said as one of the cause of aphthous ulcer, as it causes injury or chronic irritation to the oral tissues [10]. Many disease are associate with mouth ulcer like gastrointestinal

diseases, Behçet's syndrome, vitamin deficiencies, cyclic neutropenia, Reiter syndrome, hematological disorders, Magic syndrome, PFAPA (periodic fever, aphthous pharyngitis and cervical adenopathy), Sweet syndrome etc[11,12].

Minor ulcers take short time to heal and are small in size. Major ulcers take long time to heal and often lead to scarring. Herpetiform are multiple pinpoint ulcers which heal within a month and are usually found on the tongue.

Definition

Aphthous ulcer is the most common and painful condition which occurs in the oral mucosa. It is basically the breaching of the oral epithelium exposing the nerve endings in the underlying lamina propria. Due to this severe pain is experienced along with soreness, swellings and redness.

Description

Aphthous ulcer is small, round or ovoid ulcers having margins around. They are yellow or grayish in colour. It usually occur only the areas where the skin is not tightly bound to the bone like the inside of lips or cheeks and the dorsum of tongue. The three different types of aphthous ulcers are classified based on the difference of their shape, size, duration and scarring. These are as follows

Minor ulcer is a mild aphthous ulcer whose size varies from 8-10 mm. It is found mostly in non keratinised mucosal surfaces like buccal mucosa, labial mucosa and the floor of the mouth. These will heal in a short period of time like 10-14 days. There may be burning sensation prior to the appearance of the lesion. These do not lead to scar while they cure.

Major ulcer is a rare condition affecting only 10-15% of the population. Its size will reach upto 1cm in diameter. The areas commonly affected by major ulcer are the lips, soft palate and fauces. Sometimes the dorsum of the tongue and gingiva will also be affected [13]. It will last for 6 weeks. This will also lead to scarring.

Herpetiform ulcer is characterized by small multiple ulcers 100 in number. They are 2-3mm diameter. These are small in size and combine to form a large irregular ulcer. These ulcers last for 10-14 days. These are common in women. These usually do not form scars.

Aphthous ulcer can affect the genitals of males and females. It is more common in females than in males. It usually occurs during adolescences or childhood. The aphthous ulcer in the genitals is called as Non Sexually Acquired Genital Ulceration.

Herpes Simplex is an infection. Depending on their position these can be classified as oral herpes or genital herpes. Oral herpes is the sores around the mouth or face. Genital herpes affects the genitals mainly. This is a sexually transmitted disease (STD). Herpes simplex is of two types - HSV-1: This type occurs usually around the mouth and can be transmitted to the genitals during oral sex.
HSV-2: This is mainly on the genitals. It is spread through sexual contact and skin to skin contact. It is a very common and contagious disease.

Associated Factors

The exact etiological reason for the occurrence of aphthous ulcer has not been found yet. But it is s considered to run in the family. In present date it is thought to be caused by the disturbance in the immune system, which will react against the protein of the mucosal tissue. Sodium lauryl sulphate is a detergent found in toothpastes that also cause the growth of ulcer in some individuals [14]. Apart from these some of the associated factors leading to ulcers are nutritional deficiency, trauma, drugs, and hormonal changes.

Nutritional Deficiency

Deficiency in vitamin B12 and iron can lead to decrease in the thickness of the oral mucosa. As the thickness reduces there is maximum chance of it to get worn out and cause lesions.

Genetics

Ulcers due to genetic reasons develop at an early age and are severe in condition. This is seen in 40% of the population [15]. These will be seen at an early stage of life and causes a lot of discomforts.

Trauma

Injury in the oral mucosa due to brushing, disturbances due to teeth etc will also lead to ulcer in the mouth [16]. These reasons will lead to opening of the wound and hence expose the nerve endings leading to lesions. Trauma is basically here referred to as the abberations of the oral mucosa.

Drugs

Many drugs are considered to induce the growth of ulcers in the mouth. Drugs like propionic acid, diclofenac, piroxicam, phenobarbital, sodium hypochloride, phenindione, gold salts and nicorandil [17].

Hormonal Changes

Hormonal changes in women are also associated to ulcers. During menstruation or in the luteal phase of menstrual cycle there are high chances of ulceration [18]. Also by the use of contraceptive pills there is a change in the hormonal levels.

Smoking

In contrary to the causes of ulcers, smoking helps in protection against aphthous ulcers. Smoking is usually considered to be hazardous to health and cause many oral and skin related problems but it has been found out to be protective in function in this case.

It has been found that the smokers have increased keratinization of the oral mucosa. This increase protects the oral mucosa from any kind of infection. It has been assumed that the absorbed constituents from the cigarette lead to increase in keratinization. However hyperkeratosis is considered as premalignant [19]. Even though smoking is one factor which is protective against ulcers, it is cancerous.

Treatment

Several tests can be done to diagnose aphthous ulcer like blood test for blood count, B12, iron. The general treatments taken are use of protective pastes forming a layer on the ulcer reducing irritation and exposure of one of which is Amlexanox paste, avoiding stress, proper intake of vitamins and minerals and antibacterial mouthwash to avoid secondary infection, ignore food stuffs that aggravate ulcers. Benzydamine hydrochloride mouthwash can also be used for treating ulcers.

Topical steroids are also commonly used to treat aphthous ulcer. These include the dexamethasone ointment or to their lesion 3 times daily after meals for 5 days. Topical steroids are usually in the form of paste, cream or lotions, often triamcinolone is in pastes.

Nowadays Low Level Laser Therapy (LLT) is used to treat the aphthous ulcer as it is a fast pain relieving and heals fast. It has fewer side effects than the medicine taken for the treatment of ulcer. It is also cost-effective. It is one of the most appropriate treatments for minor ulcers.

Topical drugs and systemic drugs are used for the treatment of ulcers. Topical drugs are used to treat when the outbreaks are continuous and pain with minor aphthae. The drugs are amlexanox or topical corticosteroids such as triamcinolone acetonide are used to prevent the formation of lesions.

Systemic drugs are used when the outbreak is constant and aggressive with major aphthae and intense pain. Different drugs like colchicine, dapsone, clofazimine and the most commonly used systemic corticosteroids such as prednisone and immune modulators such as thalidomide.

Prognosis

Ulcer can range from minor to a deep one. It causes a lot of discomfort while eating, swallowing which will lead to loss of appetite and weight loss. These do not cause oral cancer or any infection. Aphthous ulcer can usually last for several years before spontaneously disappearing in later life [20].

Conclusion

Aphthous ulcer is a very painful condition which is given least importance but if left unattended can cause severe pain and impact on the quality of life. The duration of a specific ulcer might range from few days to few weeks or sometimes even can last for months. The exact cause of ulcer is unclear. LLLT is a safe, effective and fast way to get rid of ulcers. Topical drugs and systemic drugs are used as treatment.

Abstract

The aim of the review is assessment ofpain and pain control measures during orthodontic therapy. Pain and discomfort are the two main clinical symptoms appreciated by the patient who is undergoing orthodontic therapy mainly fixed appliance. Pain during orthodontic treatment can discourage the patient from seeking treatment and discontinue the treatment.To compare the different methods ofpain control assessment during fixed orthodontic therapy.

Key word: *orthodontic therapy, pain control,painscale,noxiousstimuli,pain control assessement.*

Introduction

Pain is subjective response with a large individual variation and it's a sensation evoked by noxious stimuli. Pain and discomfort are the two main clinical symptoms experienced by orthodontic patients usually after placement of fixed appliance for 2-4 days [1]. Pain does not localize only to the supporting tissues (PDL) due to force applied to the teeth, but also to surrounding soft tissues, which is due to attrition caused by arch wires and brackets. Pain being a major concern for the patients now a days and it's the main reason for discontinuing orthodontic treatment and discourage patients from seeking treatment [2]. According to O'Connor 2000, pain as a greatest dislike during treatment and fourth among major fear and apprehension prior to orthodontic treatment.Pain depends on

certain factors, that include age, sex, stress, emotional state, magnitude Of force applied etc. According to Amy M. Krukemeyer et al 2009, in his survey he has stated that more than 58% of patients strongly agreed and agreed with the statement “I have pain for few days after an appointment” and 20% answered with a neutral fashion but no one disagreed with the statement.

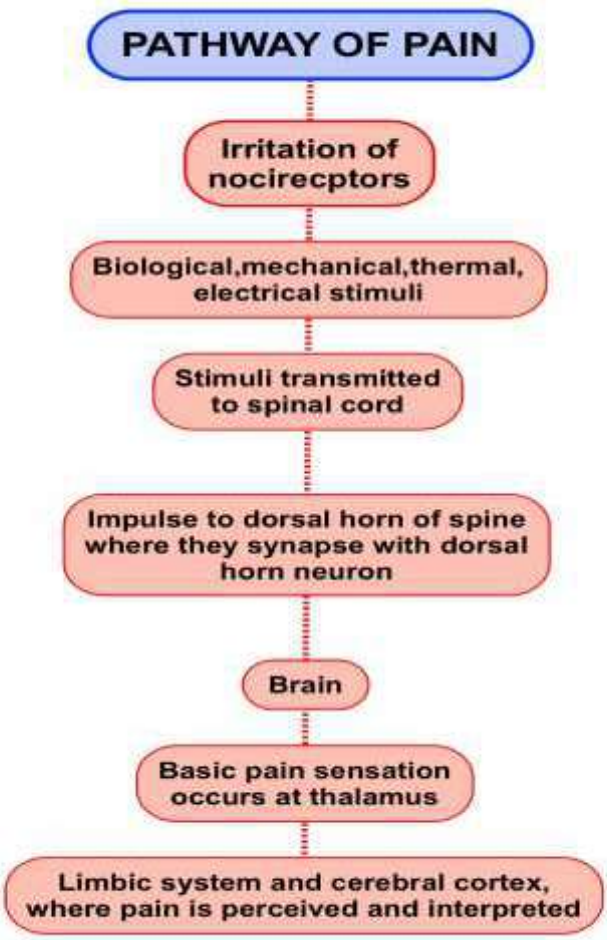

Figure 1: Pathway of Pain

Causes

Pain depends on certain factors and it is caused during placement of separator, placement of arch wires and activation, application of force for tooth movement and during debonding. Pain experienced during fixed appliance is more when compared to removal appliance therapy [3]. Beyond these factors, other factors include age, gender, physiological and psychological well beingof the individual. It has been reported that

adults experience more pain than pre-adolescents and females experience more pain when compared to male [4].

Pain during orthodontic separation

During orthodontic separators like brass wires, elastomeric and spring type steel separator will cause pain. Pain starts within 4 hours of placement and subsides within 5 days of placement but pain being at its peak at 2ndday [5].

Pain during arch wire placement

Pain experienced during arch wire placement varies with different types of arch wires used. Pain usually starts after 4 hours of placement and lasts for 2-3 days and it shows diurnal variation – evening and nighttime elevated pain [6]. It has been reported that anterior teeth experiences more pain than posterior teeth as anterior teeth is involved in functional movements like biting, and difference in root surface anatomy. Likewise pain in lower jaw is more than in upper arch [7].

Pain during arch wire activation

Pain exerted during activation often leads to avoidance of chewing hard food, which in turn leads to deficient dietary intake [8]. Through different experimental studies, masseter muscle activity after activation of arch wire has been evaluated and stated that the activity of masseter muscle has been reduced due to external stimuli. Pain elicited during activation of arch wires affects dietary intake and basic day to day like activities [9].

Pain during application of force

Degree of pain and magnitude of applied force are interrelated. Higher the magnitude, higher the pain experienced by the patients. There is no significant relation between pain and severity of malocclusion. However be the malocclusion, mild to severe patients undergoing fixed appliance therapy will experience pain [10].

Pain during Debonding

Tooth mobility and force applied during debonding are the two main factors responsible for pain during debonding [11]. Pain during debonding is comparatively minimal and can be minimized by placement of occlusal wax rims and cotton rolls.

Other Factors

There is a relationship between physiological and psychological aspect of individual with pain perception during orthodontic therapy. Pain experienced by the individual doesn't completely depend on magnitude of force but it also relies on psychological well beingof the individual [12]. Pain perception with age in orthodontic treatment is a bias because Of different treatment approaches for different age groups. But some studies have revealed that adult patients experience more pain than young individuals [13].

Pain Mechanism

Tooth movement during orthodontic treatment causes inflammatory changes in the periodontium, which stimulates the release Of various biochemical mediators responsible for causing pain. Orthodontic pain is due to change in blood flow caused by orthodontic appliance and are related with the release Of various biochemical mediators like histamine, dopamine, serotonin etc.[14]. Initial step in pain is the irritation ofnocireceptors, which are free nerve endings that responds to pain stimuli. Nocireceptorsare seen in locomotory organs, skin, cornea and dental pulp. The stimulus is Of various sources – biological, mechanical, electrical and chemical stimuli. The stimuli are transmitted to spinal cord then to the central areas of the brain, where pain perception takes place. Impulses run to dorsal horn of spine where they synapse with dorsal horn neuron and enter the brain. Pain is carried by two fibers- A delta fibers and C fibers. Delta fibers are the large fibers usually involved in production of sharp and well defined pain, they are myelinated and have capacity to travel at a rate Of 20 meters/second to the central nervous system. Stimulated by electric shock, physical blow and cut. C fibers are demyelinated fibers and are thin and are easily susceptible to damage. Absence of myelin sheath conducts pain stimuli at a slower rate at about 2 meters/second. Pain will be rapid and pulsating [15,16].

Pain classification

According to orthodontic mechanics by Burstone in 1962 into two ways

(i) Relationship of application of force

(ii) Time of onset.

According to application of force

1) First degree – teeth moved by appliance
   Eg.Band pusher, force gauge.
2) Second degree – pain during clenching and biting.
3) Third degree – unable to bite or chew food of normal consistency.

According to time of onset

1) Acute/immediate- sudden application of heavy force.
2) Chronic/delayed- due to light to heavy force and the intensity decreases over time [17].

Pain Assessment

Pain assessment is done by measuring the intensity of pain through visual analog scale (VAS), which has a rating scale with minimum constraints to evaluate pain perception. VAS is a line whose ends are anchored and measures the intensity of pain by grading scale from 0-10. The individual with pain is expected to a mark on the scale corresponding to the pain experienced by them from 0-10 (0 as no pain and 10 as severe unbearable pain). Pain score of the individual is assessed from the pain scale [18].

Pain management

Relieving pain is one of the most important because pain causes depression, irritation and outburst of anger. It doesn't allow the individual to lead a normal life with family leading to isolation, elimination from social life and dramatically reduce sense of mind [19]. Various modalities include pharmacological approach, physical therapy and invasive method.

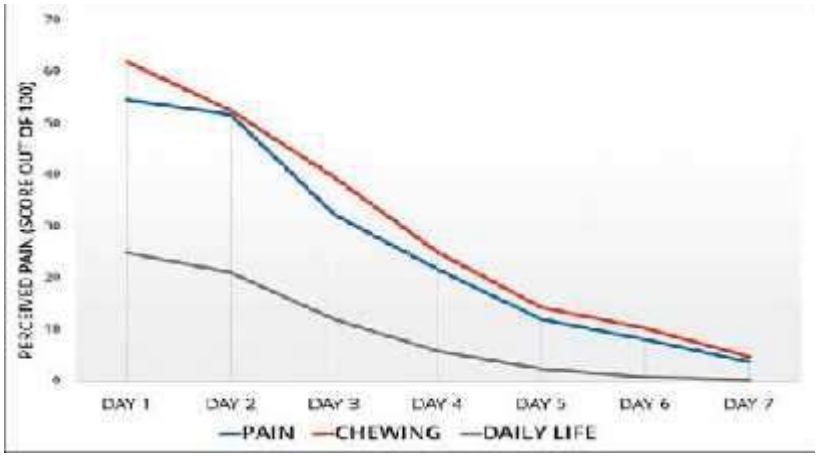

Figure 2: Pain Scale

(i) **Pharmacological approach**

Pharmacological approach includes opioid analgesics – paracetamol and NSAIDS (ibuprofen, aspirin). Analgesic will inhibit the synthesis of prostaglandins at the site of injury. It also includes anesthetic gel, bite wafers and vibratory stimulation. There is no universal recommendation for the use of analgesic for orthodontic pain. Low dose for the first 2-3 days will not affect or interfere with tooth movement. Contraindicated in patients who are allergic to selective drugs [20].

(ii) **Physical therapy**

It includes method of physical treatment- cryotherapy (cold), thermotherapy (heat), laser therapy and manual techniques. Physical treatment doesn't completely eradicate the pain but it helps to improve the life of the individual [21].

(iii) **Invasive methods**

Invasive methods are carried out only when there is no response or relief for the individual through the other pain management methods. In invasive method the management of pain is through local anesthesia – nerve blocks by intrathecal administration of drugs, neurosurgery and neurolysis [22].

Literature Of review

Angelopoulou, conducted a meta-analysis to evaluate the effect of non-steroidal anti-inflammatory drugs (NSAIDs) in managing pain. Among 1,127 studies, seven were included. No statistically significant difference was found between ibuprofen and paracetamol (acetaminophen) administration in relieving pain. It was evident from the literature that ibuprofen lowered pain at two hours and six hours after intervention but not at 24 hours when pain peaks. To some extent, ibuprofen relieves pain in the initial stage of treatment. Hence, it was considered a safe and effective drug compared to other NSAIDs and also had comparatively fewer adverse effects. A report based on a literature review states that NSAIDs impede tooth movement and also increase the risk of root resorption. Therefore, paracetamol (acetaminophen) was considered the safest NSAID that had no influence on the range of tooth movements as well as root resorption and other adverse effects that might occur within the oral cavity [26].

M. Abu Al-Melh and Andersson, the effect of lidocaine/prilocaine topical anesthetic was investigated on pain and discomfort attributed to the insertion of elastomeric separators. Hence, the overall mean discomfort/pain score was found to be significantly lower ($p<0.001$) with the topical anesthetic as compared to the placebo group. Therefore, this methodology might be beneficial for patients with a low pain threshold as it could potentially relieve pain and discomfort after the placement of orthodontic elastomeric separators [27].

In 2003, a study made with 200 adult patients, evaluated the reasons which led them to initially reject the suggestion to undergo orthodontic treatment. The researchers found out the reasons to be, from the highest to the lowest prevalence: Long treatment time, the

discomfort of wearing orthodontic appliances, rejection to the anti-esthetic appearance of brackets, concerns about pain, and fear of disappointment with the final treatment result [29].

In 2005, a satisfaction questionnaire to be answered by 100 patients treated in the Academic Center of Dentistry in Amsterdam three years after they completed their orthodontic treatment. In that study it was observed that the most important issue in determining patient satisfaction was the good orthodontist/ patient relationship during treatment and that female patients revealed lower satisfaction levels with the dentofacial improvements achieved by treatment when compared to male patients [29].

Conclusion

The experience of pain is a complex phenomenon that comprises of behavioral, emotional, physical and interpersonal aspect. Psychological factors also play an important role in pain, where in chronic pain it leads to disability and distress associated with pain. Pain differs from patient to patient, as they vary in magnitude, threshold level and amount of force applied. There is a evidence that education and cognitive behavioral intervention for pain can improve the attitude of individual towards orthodontic treatment, eliminate disability and distress associated with pain.

Abstract

The aim of this review is to assess the relationship between C reactive protein and cardiovascular diseases. Physical activity is associated with a reduced incidence of coronary disease, but the mechanisms mediating this effect are not defined. Inflammation has been seen to show an interest in the pathogenesis of cardiovascular disease. Some of the beneficial role of physical activity may result from its effects on the inflammatory process.Cardiovascular disease (CVD) is currently the leading cause of death and disability in the developed world, and will soon overtake infectious disease as the pre-eminent cause of death worldwide. A substantial body of evidence has suggested that four modifiable risk factors — smoking, diabetes, hypertension and hyperlipidaemia account for a significant proportion of CVD, and that reduction of these risk factors leads to reduction in morbidity and mortality. Interleukin-6 (IL-6) and C-reactive protein (CRP) are markers of systemic vascular inflammation that herald atherothrombosis and may have important interrelationships with traditional cardiovascular risk factors. Although markers of systemic inflammation may have a role in the development of hypertension, supportive clinical data remain limited. IL-6 and CRP were measured from baseline bloods. After multivariate adjustment and strong confounding by body mass index, IL-6 was found weakly associated and CRP strongly associated with hypertension risk.

Keywords - *Cardiovascular disease, CRP, Inflammation, Interleukin, Risk factors.*

Introduction

Inflammation is seen to play an important role in the etiology of coronary heart disease (CHD) [1, 2], but the mechanism by which it acts is poorly understood. A short-term inflammatory response is produced by exercise, but from both cross-sectional and longitudinal studies, it is discovered that exercise demonstrates a long-term “anti-inflammatory” effect. This anti-inflammatory response adds to the good effects of regular physical activities. Inflammatory reactions that occur in coronary plaques are seen to play an important role in the development of acute atherothrombotic events. It is seen that inflammation anywhere else is also correlated to atherogenesis and also its thrombotic complications. In recent studies it is noted that systemic markers of inflammation can identify people who are at a high risk of cardiovascular diseases.

Considerable interest has been focused on C-reactive protein (CRP) which is a systemic marker of inflammation in order to improve the cardiovascular risk prediction.CRP has been used to detect the incidence of myocardial infarction, stroke, peripheral arterial disease, and also sudden cardiac death in a patient. CRP levels also have the ability to predict risk of both recurrent ischemia and death in the patients having stable and unstable angina or in those arriving at the emergency rooms showing acute coronary syndromes. It has come to the conclusion that atherothrombosis, is a chronic inflammatory disease in addition to being caused due to lipid accumulation. This is supported by various studies showing clinical evidence of the same [3].

In clinical application, CRP is seen to be a better predictor of cardiovascular diseases when compared to the LDL cholesterol. CRP levels of <1, 1 to 3, and >3 mg/L corresponds to low-, moderate-, and high-risk groups respectively; this is calculated by using widely available high-sensitivity assays. There are a few instances where individuals may present with LDL cholesterol below 130 mg/dL but their CRP levels >3 mg/L. This denotes that they belong to the high-risk group but are often missed out in clinical practice. By making CRP evaluation mandatory in addition to cholesterol evaluation, it forms a simple and inexpensive method by which risk prediction can be improved.

Recently there has been evidence sating that inflammation plays a role in the atherosclerotic process [4]. The predictors of the disease was thought to be cytokines and acute-phase reactantshence they were examined. C-reactive protein (CRP) was found to be highly sensitive

and has assay characteristics that make it easy for clinical use. CRP has been shown to have a dose-response relationship to coronary heart disease. It was also noted that CRP is independent of all other major risk factors [5]. There is well documented evidence which shows that physical activity plays an important role in preventing coronary heart disease [6].

Several studies have shown that elevated plasma levels of fibrinogen, C-reactive protein (CRP), and interleukin-6 (IL-6) are associated with the risk of CHD and the severity of atherosclerosis [7, 8]. Whether these molecules play a causative role, or simply act as markers of the acute phase reaction, is debatable [9]. High blood pressure (HBP) is one of the most important risk factors for cardiovascular–renal disease.In spite of its high health impact, primary prevention of HBP is partly hampered because of a limited knowledge of HBP risk factors [10].C-reactive protein has been shown to be associated to HBP in a few well-controlled studies [11, 12, 13]. On the other hand, results from studies on the association between interleukin-6 (IL-6) and HBP have been contradictory [14, 15].The interplay between the inflammatory process, cardiovascular risk factors, and atherothrombosis is complex [16].Despite evolving theories regarding IL-6 and CRP in the central mechanisms of inflammation and atherogenesis [17],there exists a paucity of data coherently relating clinical cardiovascular risk factors with circulating levels of systemic vascular inflammatory markers in healthy individuals. It is seen that there is astrong and association between the CRP levels and the clinical features of atherothrombotic disease, this was described in studies of patients suffering from acute myocardial ischemia [18]or myocardial infarction [19, 20],stable and unstable angina pectoris [21],and myocardial infarction or recurrent ischemia among those hospitalized with angina pectoris [22].The aim of this review is to understand the correlation between the systemic inflammatory marker CRP and cardiovascular diseases.

C-Reactive Protein

CRP was first discovered in 1930 by William Tillet and Thomas Francis at the Rockefeller Institute for Medical Research, in New York. In studying the blood of patients suffering from acute Streptococcus pneumonia infection, it was found that the sera of these patients formed a precipitin with an extract from the streptococcal bacterium. The extract was originally labeled

Fraction C, and was later confirmed as a polysaccharide. Hence, as a result of its reactivity with the C polysaccharide of the Streptococcus cell wall, the 'substance' in the sera was named CRP.A decade later, Oswald Avery and Maclyn McCarty-the research team who originally described the "transforming principle" and the concept that genes are made of DNA also described CRP as an "acute-phase reactant" that was increased in serum of patients suffering from a spectrum of inflammatory stimuli, including myocarditis and the inflammation associated with rheumatic fever [23].

CRP belongs to the pentraxin family of calcium dependent ligand-binding plasma proteins. The human CRP molecule is composed of five identical non-glycosylated polypeptide subunits each containing 206 amino acid residues.

C-reactive protein (CRP) is a derived from the liver and plays an important role in the innate immune response. CRP is known to have a long plasma half-life period. This is helpful as it acts as a marker for atherothrombotic disease. A large number of studies had been carried out in individuals who had no history of cardiovascular diseases, it was seen that a single CRP level test done is able to predict the vascular effects of the individual. The relationship noted between a patient's CRP levels and risk of cardiovascular disease has seen to be consistent with various studies conducted in USA and Europe. It also supports the fact that CRP is independent of the various risk factors such as age, smoking, cholesterol levels, blood pressure, and diabetes. These effects are present among women as well as men, among the elderly as well as those in middle age, among smokers and non-smokers, and among those with and without diabetes. CRP levels have long-term predictive value. CRP still acts as a strong predictor of risk for cardiovascular diseases even after the initial blood samples were collected 20 years ago [24].

The recent use of highly sensitive CRP assays, with international reference standards set by the World Health Organization (WHO) [25]has established international reference standards using which the highly sensitive CRP assays are done and calculated. By this method, it simplifies the use of CRP as an internationally accepted predictor of cardiovascular events. Large number of prospective studies done in apparently healthy individuals confirmed the prognostic relevance of CRP to (i) the risk of cardiovascular disease in men [26],women [27],and the elderly [28] ; (ii) the risk of fatal coronary disease among smokers with multiple risk factors for atherosclerosis[29]; (iii) the development of peripheral vascular disease [30]; and (iv) the risk of

coronary heart disease (CHD) in a large cohort of initially healthy middle-aged men [31]. The synthesis of CRP by the liver is largely regulated by IL-6. The activated leukocyte is widely assumed to be the major source of circulating IL-6, with additional contributions from fibroblasts and endothelial cells [32].

C-reactive protein (CRP) is not seen to be directly involved in the coagulation process; it acts as a sensitive marker for inflammation [33], tissue damage and also infections [34]. CRP is seen to have a plasma half-life of about 19 hours. CRP half life remains identical under all conditions. It is in rapid in contrast to the other elements seen such coagulation proteins and all major acute-phase reactants, hence synthesis rate of CRP acts as the direct determinant of its plasma concentration [35]. Excellent anti-CRP antibodies and a well-established World Health Organization (WHO) international reference standard for CRP [36] are available, so precise, sensitive, and robust clinical serum/plasma assays can be readily undertaken [37, 38].CRP measurement thus has many advantages in the detection and monitoring of the acute-phase response in general and the relation to atheroma and its complications in particular. The recent use of the highly sensitive CRP assays was done in a large prospective study among patients with angina pectoris [39]and in initially healthy subjects [40]. There was a consistent positive association between baseline CRP levels and cardiovascular diseases. In order to prove the correlation between the CRP levels of an individual to coronary heart disease (CHD) risk, the serum CRP in 936 initially healthy men were drawn from a random sample of the general population and were measured at Augsburg in 1984 to 1985.8 years later a follow up was done where they were able to prove the prognostic significance of CRP values which were able to show the occurrence of a first major coronary event in these men [41].

Inflammatory Markers

In an effort to better identify patients at high risk for cardiovascular events; several markers of risk have been proposed to be used for screening patients and identifying those who have a high risk for cardiovascular diseases. The various markers includehomocysteine and fibrinogen levels, fibrinolytic capacity, and levels of apolipoprotein A-I, apolipoprotein B-100, and lipoprotein. However, the clinical value of many of these markers has been limited because of inadequate standardization of assay conditions, inconsistency of prospective data, or lack of evidence of

significant improvement in the prediction of risk over that afforded by standard lipid screening alone. As atherosclerosis is recognized as an inflammatory process, various plasma markers of inflammation are being investigated to see if they could behave as a marker for risk of cardiovascular diseases. There are markers of systemic inflammation produced in the liver which are, high-sensitivity C-reactive protein and serum amyloid A. Cytokines such as interleukin-6; and adhesion molecules such as soluble intercellular adhesion molecule type 1 are also seen.It is seen that these factors are proposed to predict cardiovascular diseases; however, the prognostic value remains uncertain [42].

Relationship between CRP and CVD

There has been much interest in the prognostic significance of raised levels of C-reactive protein in patients with angina [43], with the proposal that it points to release of IL-6 by activatedmacrophages in an unstable plaque [44]. More recently, however, the observations that raised concentrations of CRP in healthy subjects predicted the incidence of CHD over a period of years [45] have suggested a role for inflammation in the initiation of atherosclerosis as well as in the precipitationof an acute event. Patients with COPD had higher levels of CRP than control subjects in all studies. Even in population based studies, which are less susceptible to selection bias, a strong relationship was observed between CRP and COPD which suggests that COPD is, indeed, a risk factor for increased CRP in the community.In addition to lipid screening and the Framingham Risk Score, CRP is capable of predicting the risk for cardiovascular diseases, this gives additional prognostic information.

In outpatient settings, the primary use of CRP should be at the time of cholesterol screening, when knowledge of CRP can be used as an adjunct for global risk assessment. For individuals with LDL levels above 160 mg/dL and for whom the guidelines already call for therapeutic intervention, an elevated CRP level should aggressively encourage physicians and patients to institute pharmacological therapy in those instances where none is currently being used or where compliance is poor [46].

For individuals with LDL levels between 130 and 160 mg/dL, and if the CRP level is seen to be high, then it acts as an extra finding which leads to a higher risk for cardiovascular disease..

For individuals with LDL levels below 130 mg/dL, the finding of an elevated CRP implies substantially higher risk than predicted on the basis of LDL alone. Individuals who present with low LDL levels and high CRP levels have a higher risk of having the metabolic syndrome and fasting glucose levels must be recorded for these patients. Randomized trial is done on a large scale so that evidence is obtained before advising the patient for the statin therapy.

Framingham Risk Score assesses the patients, and only those who have intermediate risk are subjected to CRP level test. By this method unnecessary testing procedure can be avoided for patients.Clinicians can selectively pick a few individuals for whom CRP is calculated. The clinician makes the choice based on the calculated 10-year Framingham risk when it is seen to be between 5% and 20%. This approach is seen to require a second office visit and also a second phlebotomy; hence it is less efficient and perhaps less cost-effective [47].

Aggressive therapies must be started for secondary prevention; here the role of CRP is less certain. Hence LDL evaluation method is carried out so as to assess the statin efficacy.

In the setting of acute coronary ischemia and unstable angina, the role of CRP is rapidly evolving. There have been many studies conducted which shows that CRP has the ability to predict early and late death in cases of acute coronary ischemia, thus it enhances the predictive ability in addition to cardiac troponin. Knowledge of inflammatory status has been seen to be useful in distinguishing patient subgroups which are more or less likely to gain from an aggressive approach when compared to a conservative management approach [48]. However, appropriate clinical cut-points for CRP in the setting of acute ischemia remain uncertain, as does the timing of CRP evaluation in relation to the onset of ischemia. In the emergency room setting, the most common use of CRP is to detect those with chest pain syndromes and those who have negative troponin levels. If CRP level is seen to be increased in this setting, it is generally associated with long term and short term risks. More evaluation tests need to be conducted for the same. Current data states that the patients in the emergency room setting who have negative troponin levels and negative CRP levels are highly unlikely to have any flow limiting coronary disease [49].

The synthesis of CRP is predominantly under the control of IL-6 [50] which in turn has been assumed to originate largely from activated leukocytes, either in the vessel wall itself or at a

remote site of infection [51]. The correlations between these antibody titers and concentrations of fibrinogen, TNF-a, and IL-6 were weaker and generally insignificant. Endothelial dysfunction indicators were seen with the help of raised levels of CRP and also raised levels of cytokines. Tracy et al have stated that there are associations of CRP levels and a variety of measures of procoagulant activity and fibrinolysis [52]. They have suggested that this is either because of inflammation in underlying atherothrombotic disease or due to the inflammatory cells which are activated by the ongoing coagulation processes.

Goals of Screening

Cardiovascular screening programs should have their primary aim to identify the high-risk individuals. These high risk individuals can be then advised for smoking cessation, diet, exercise, and blood pressure control. It is a known fact that lifestyle recommendations is directly associated with the risk for cardiovascular disease. Using both the CRP level and the lipid evaluation, there is improved prediction of the risks for cardiac diseases seen.

It has not been found out that reduction of the CRP levels would in turn reduce the rates of the cardiac events. Studies are currently being done for the same. It has been found out that when the cardiovascular risk is reduced, there is also a reduction seen in the CRP levels. For example, reduction of weight, healthy diet, regular exercise and cessation of smoking has seen to lower both the cardiac risk as well as the CRP level.

There are several drugs which have the ability to reduce the cardiac risks which have an influence on the CRP level. Statin drugs are capable of that action; various studies have been conducted using these drugs which show an average reduction of CRP levels seen around 6 weeks after the usage of the drug. Aggressive LDL reduction is done as a critical treatment goal. LDL level evaluation must be done on a regular basis so as to monitor the statin compliance of the patients. Hence it is still regarded as one of the primary evaluation tests. LDL levels have seen to be reduced with the help of statins, but it is noted in some cases where the CRP levels reduce and other cases where the CRP levels remain unchanged [53].

Measuring CRP

In clinical practice, if the CRP level is found to be less than 10 mg/L, a single assessment is sufficient. In cases of major infections, trauma or even hospitalization, there is a raise in the CRP levels greater than 10 mg/L. This value must be ignored and another test must be scheduled on another date when the patient is seen to be clinically stable. It has been advised by many to use two measures of CRP level and then using the lower value of the two, or the average value of the two as the final level of CRP. Cholesterol evaluation is also done in order to provide a better picture on the risk of cardiac disease. There have been a few cases where the CRP is highly elevated, systemic inflammatory conditions such as lupus, inflammatory bowel disease or endocarditis must be considered. In these cases there is an increase of the erythrocyte sedimentation rate seen [54].

CRP levels are seen to be stable for long periods of time. It is not affected by food intake etc. hence it is not required to take fasting blood samples to estimate it. CRP is an acute phase reactant and its variations are seen to be similar to those associated with cholesterol screening in individuals. The individual is said to be out of risk if the CRP is within normal clinical limits [55].

The normally used assays to assess CRP are not sensitive enough to provide accurate cardiac disease risk prediction. In order to prevent this problem, highly sensitivity CRP assays were introduced and is now widely used [56]. The cost of CRP screening is comparable to that of standard cholesterol evaluation and far less than almost all other alternative approaches to cardiovascular screening under consideration. Owing to its low cost and also its long term of use, CRP screening is seen to be very efficient [57]. In many settings, the inexpensive approach of adding CRP to LDL screening may yield immediate cost-savings in terms of negative predictive value and the subsequent avoidance of unnecessary clinical testing, particularly when compared with far more expensive screening approaches such as electron beam calcium tomography or MRI.

It was noted that the CRP levels which were well within the range detected using the highly sensitivity assays have shown specificity for vascular events [58]. Some doctors have started using CRP as part of a normal routine annual check up.

Comparing CRP to Other Risk Predictors

Apart from CRP evaluation other methods such as, sophisticated measures of cytokine activity, cellular adhesion and immunologic function are able to predict myocardial infarction and stroke as they show elevated levels in those with increased vascular risk. These other methods to assess risk is not used a lot as the assays are either not appropriate for clinical use or that the protein of interest in use has a very short life period. Fibrinogen is a biomarker which is involved in both inflammation as well as thrombosis. Measuring fibrinogen is not commonly done due to limit in methodology and as it is not standardised. Systemic inflammation can be measured by using white blood cell count or by using the erythrocyte sedimentation rate. This has been proved unreliable in the clinical setting and hence is not in use. CRP evaluation is preferred [59]. Highly sensitive assays have been developed for CRP and are being standardised across the commercial platforms.Due to the high stability of CRP, it is possible to measure accurately its levels seen in both fresh and frozen plasma without the need of being collected in some special method. The stability of CRP is seen to be due to its highly stable pentraxin structure. CRP having a plasma half life period of about 19 hours owes to it being stable [60].

Evaluation of other markers such as lipoprotein(a) and homocystein are done in cases where there is premature and unexplained atherosclerosis. It is seen that the reliability of assessing CRP levels is greater when compared to these other markers. Studies indicate that CRP is a better predictor of risk when compared to the resonance based evaluation of LDL concentration and particle size [61].

Conclusion

CHD is the leading cause of death and disability in developed nations and is increasing rapidly in the developing world. Up to half of all events associated with CHD are reported to occur in apparently healthy individuals who have few or none of the traditional risk factors, including dyslipidemia. As a result, attention has increasingly turned to the role of other factors, such as inflammation, in the development of atherosclerosis and CHD. In conclusion, CRP levels seem to be correlated with levels of heart disease risk. In fact, CRP seems to predict cardiovascular risk at least as well as cholesterol levels do, thus enabling early diagnosis of CVDs and may provide new directions for prevention of cardiovascular events. .

Abstract

Astragalus is a plant native to Asia. Astragalus has been utilized as a part of Traditional Chinese Medicine for a large number of years, regularly in mix with different herbs, to tone and reinforce the body. The Chinese name of the herb,huang qi, means "yellow leader", because the root is yellow and it is considered to be one of the most important herbs in traditional Chinese medicine. The root of the plant is used medicinally.In Chinese medicine, they traditionally convert astragalus into a decoction, it means the roots of astragalus are boiled in water and then removed. It is usually combined with other herbs, such as ginseng. In some health food stores it is found in supplement form. The potential utilisation of this herb and its compound constituents in medicines of fiery sicknesses and growths has been effectively explored lately. Astragalus-based medicines have exhibited noteworthy improvement of the danger actuated by other simultaneously controlled standard medications (e.g., immunosuppressants and tumour chemotherapeutics). The significant parts of Astragalus membranaceus are polysaccharides, flavonoids, and saponins. Contemporary utilisation of Astragalus membranaceus for the most part centers around its immunomodulating, hostile to oxidant, and calming, and also anticancer impacts

Key Words: *Astragalus membranaceous, Huang Qi, Bei Qi, Hwanggi, Milk Vetch.*

Introduction

Astragalus which is also called as milk vetch, locoweed etc belongs to the legume family Fabaceae and subfamily faboideae. It is said to be the largest genus of plants. Some species like lepidoptera uses astragalus as a food plant. It also has some uses as herbal medicine. Ithas been used in China as a popular herbal tonic for centuries. It strengthens the body's resistance to disease and increases energy by enhancing cell growth and longevity and simulating the synthesis of antibodies. It has a tonic effect on the liver, heart, lungs and kidneys. It lowers blood pressure and increases circulation. It enhances the production of interferon, which prevents viruses from replicating inside the body [1, 2].

It comes from the root of a perennial plant plant in the pea family that grows in the northern and eastern parts of China as well as in Mongolia and Korea. The root is usually harvested from four-year-old plants[3]. Astragalus is the source of a popular medicine called huang qi available in any drugstore in China for use against colds, flus and other respiratory infections. Astragalusis still widely used in China for treatment of chronic hepatitis and as an adjunctive therapy for cancer and as a folk or traditional remedy for heart disease [4, 5]. Astragalus has also been promoted for stimulation of the spleen, liver, lungs, circulatory, and urinary system, to help treat arthritis, asthma, and nervous conditions and to lower blood sugar levels and blood pressure.

Astragalus root has been used in traditional Chinese medicine for centuries as a restorative tonic; it is considered a sweet, warming herb with effects on many organs. It is used either alone or with other herbs to help with aging, improve energy, and stimulate the immune system during conditions such as the common cold, blood disorders, cancer and HIV/AIDS [6, 7]. It is also used as an adaptogen, which is meant to increase general resistance to stress and disease, and normalise disturbances in your body's ability to balance itself. The root is sold as a supplement in tablets of different dosages [8, 9].Among its diversified clinical applications; the potential use of this herb and its chemical constituents in treatments of inflammatory diseases and cancers has been actively investigated in recent years. Astragalus-based treatments have demonstrated significant amelioration of the toxicity induced by other concurrently administered orthodox drugs (e.g., immunosuppressants and cancer chemotherapeutics). The major components of Astragalus membranaceus are polysaccharides, flavonoids, and saponins[10, 11]. Contemporary use of Astragalus membranaceus mainly focuses on its immunomodulating, anti-oxidant, and anti-

inflammatory, as well as anticancer effects[12, 13, 14]. In pharmacological studies, crude extracts of Astragalus, as well as isolated constituents showed anti-inflammatory, immuno stimulant, anti oxidative, anti-cancer, anti diabetic, cardio protective, hepato protective and antiviral activities[15,16].

Astragalaus-A Supreme Protector

Astragalus -Radix Astragali

Other common names: milk vetch, huang qi

Botanical name: Astragalus membranaceus

Family: Fabaceae (pea)

Parts used: root

Properties: sweet taste, warming and moist, immunomodulator, antioxidant, hepatoprotective, cardio protective, adaptogen, diuretic

Used for: immune system dysfunction (from frequent colds and flu, to HIV, to cancer), angina, hypertension, hepatitis, fatigue, asthma, prolapsed organs, weak limbs, hepatitis, anaemia

Plant preparations: decoctions, cooked with food, powdered, capsules, tincture

Astragalus originally comes to us from China but it has quickly integrated itself into western herbalism. In a recent poll of practicing herbalists it placed as 16th in the top 50 herbs commonly used by western herbalists.

It’s important to note that the plant we use for medicine is a specific genus and species. There are over 2,000 different species in the Astragalus genus. Some of these plants are toxic and none are known to have the same qualities as Astragalus membranaceus, although a few are used medicinally.

How Does It Work?

There's a special chemical in astragalus that actually slows down the aging process right where it happens, inside of our cells, where the blueprint of our cells resides.

Recent research has shown that this special chemical derived from astragalus can "turn on" an enzyme called telomerase (hTERT). Telomerase acts to maintain or lengthen telomeres, which extend the lifespan of your DNA. If you imagine DNA as a shoelace, telomeres are the plastic aglets at each end. It serves as a protector for your DNA because it keeps it from fraying or damaging. As you age, your telomeres shorten due to wear and tear, which gives your cells an expiration date. However, telomerase helps to preserve telomeres by making them longer. Telemerase is usually "off" in adult cells, except in immune cells, in egg and sperm cells, and in malignant cells, like those found in cancer.

The length of your telomeres is important: Researchers have discovered correlations between telomere length and susceptibility to certain aging-related diseases, like cardiovascular diseases (heart attacks, atherosclerosis, and strokes), diabetes, and cancer.

Medical Uses and Indications

1. Astragalus has been used for the following:
2. Adaptogen -- protects the body from stress and disease
3. Anemia -- One early study suggested astragalus may improve blood counts in people with aplastic anemia. The study was poorly designed, so more research is needed.
4. Colds and influenza -- In TCM, astragalus is used as part of an herbal combination to prevent or treat colds, although TCM theory holds that, in some cases, it may make colds worse. Evidence in animal and laboratory tests suggests it may act against viruses like the ones that cause colds.
5. Diabetes -- Astragalus appears to lower blood sugar. More studies are needed to determine whether it can help treat diabetes.
6. Fatigue or lack of appetite from chemotherapy -- Some studies suggest astragalus may help reduce side effects from chemotherapy. The studies have not been well designed, however. More research is needed.
7. Heart disease -- Several studies suggest that astragalus may act as an antioxidant and help treat heart disease. Other studies suggest astragalus may help lower cholesterol levels.
8. Hepatitis -- A few studies have used a combination of herbs containing astragalus to treat hepatitis. Results have been mixed.
9. Kidney disease -- Preliminary research suggests astragalus may help protect the kidneys and may help treat kidney disease. More studies are needed.

10. Seasonal allergies -- One study found that astragalus may help reduce symptoms in people who have allergic rhinitis or hay fever.

Available forms

Astragalus root may be available in a variety of forms:

1. Tincture (liquid alcohol extract)
2. Capsules and tablets, standardized and non-standardized
3. Injectable forms for use in hospital or clinical settings in Asian countries
4. Topically for the skin

Research on Astragalus

Biotechnology firms are working on deriving a telomerase activator from Astragalus. The chemical constituent cycloastragenol (also called TAT2) is being studied to help combat HIV, as well as infections associated with chronic diseases or aging. However, the National Institutes of Health states: "The evidence for using astragalus for any health condition is limited. High-quality clinical trials (studies in people) are generally lacking. There is some preliminary evidence to suggest that astragalus, either alone or in combination with other herbs, may have potential benefits for the immune system, heart, and liver, and as an adjunctive therapy for cancer".

Research at the UCLA AIDS Institute focused on the function of cycloastragenol in the aging process of immune cells, and its effects on the cells' response to viral infections. It appears to increase the production of telomerase, an enzyme that mediates the replacement of short bits of DNA known as telomeres, which play a key role in cell replication, including in cancer processes.

According to the recent research, one such species of astragalus include Astragalus radix, and their chemical composition and pharmacological activities have been widely reported. Polysaccharide, triterpene and flavonoids are regarded to its effective components.Pharmacological experiments and clinical reports show that Astragali Radix has good effects on immune-regulation, anti tumour, anti-virus, diabetes, anti-aging and so on[17].

How to Take Astragalus

Paediatric

There is not a lot of scientific evidence about giving astragalus to children, so ask your doctor first. According to TCM, you should not give astragalus to a child with fever because the herb may make the fever last longer or grow stronger. Dosage should be determined by your doctor.

Adult

Dosage depends on condition being treated, age, and weight. Work with your physician to determine the safest and most effective dosage for you. Higher doses may suppress the immune system. For best results, use a standardised astragalus supplement. Recommended doses are as follows:

1. Standardized extract: 250 - 500 mg, 3 - 4 times a day standardized to 0.4% 4-hydroxy-3-methoxy isoflavone 7-sug.
2. Decoction (strong boiled tea): 3 - 6 g of dried root per 12 oz water, 3 times per day
3. Fluid extract (1:1) in 25% ethanol: 2 - 4 mL, 3 times a day
4. Powdered root: 250 - 500 mg, 3 - 4 times per day
5. Ointment: 10% astragalus applied to surface of wound. Do not apply to open wound without your doctor's supervision.
6. Tincture (1:5) in 30% ethanol: 20 - 60 drops, 3 times a day.

Effects and Safety Concerns

People with autoimmune diseases, such as Crohn's disease, multiple sclerosis, psoriasis, rheumatoid arthritis, type 1 diabetes or systemic lupus erythematous shouldn't use astragalus unless recommended by a qualified healthcare practitioner. People who have had transplant surgery should not use astragalus. The safety of astragalus in pregnant or nursing women or children isn't known.

Possible Interactions

1. Astragalus may interfere with the effectiveness of corticosteroid medications, such

Nasacort (triamcinolone)

2. Beconase, Vancenase (beclomethasone)

3. Decadron (dexamethasone)
4. Deltasone (prednisone)
5. hydrocortisone
6. Medrol (methylprednisolone)
7. prednisolone

Astragalus - Cure Disease

Immune System and Cancer

Astragalus root has been studied extensively for its effect on the immune system. It has been shown to reduce the occurrence of common respiratory illnesses, inhibit tumour growth and bolster immune system activity in general.

The studies of its use in cancer patients is astounding. It is frequently being used alongside chemotherapy to alleviate the side effects of the chemotherapy treatments. It has also been shown to inhibit the growth of tumour and bolster the immune system[1].

Research shows Astragalus root stimulates the immune system in many ways. It increases the number of stem cells in bone marrow and lymph tissue and encourages their development into active immune cells. It appears to help trigger immune cells from a “resting” state into heightened activity. One study showed Astragalus root helps promote and maintain respiratory health. It also enhances the body’s production of immunoglobulin and stimulates macrophages. Astragalus can help activate T-cells and natural killer (NK) cells[19,20].

Longevity

Astragalus seems to prolong the life of cancer patients by supporting the immune system and inhibiting cancer growth. Scientific studies have also shown that specific constituents within astragalus are highly anti-oxidant, which slows the rate of aging.

A telomere is a structure found at the end of a chromosome and is a region of repetitive DNA. Its job is to prevent deterioration of the chromosome. Shortened telomeres are associated with poor health and aging. Astragalus has also shown that it can slow telomere shortening, giving us further clues as to how to promotes longevity.

For the Heart

Astragalus has been studied extensively for its effects on improving heart function, even in patients with extreme cases such as congestive heart failure. It can also inhibit the formation of lipid peroxides and decrease blood coagulation. Another study shows that it can strengthen left ventricular function [3,4].

As a Hepatoprotective

Astragalus root has been scientifically shown to decrease the replication of the hepatitis B virus[5]. It has also been shown to prevent damage to the kidneys and liver that has been caused by either medications or virus infections.

For the Blood and Kidneys

Astragalus is also a blood tonic. It helps to regulate fluid metabolism, and those who consume it regularly are said to rarely suffer from fluid retention and bloating.

Conclusion

Astragalus root has specific and powerful applications for cancer and immune system support, however because it also contains so many protective properties (heart, liver, kidneys) it is a wonderful herb to consider for preventive care.

Abstract

Aim

To study the decisions made by dentists on removal or retention of asymptomatic impacted third molar.

Materials and method

This study recruited 100 participants (50 OMS & 50 other speciality dentists) among the Dentistsof Saveetha Dental College.The judgement on removal or retention of asymptomatic impacted third molar under various situations was assessed using a questionnaire which had 15 questions.The response was calculated in percentage and results were tabulated.Bar graphs were also plotted comparing the response given by the OMS and others for each situation.

Results

Most of the decisions made by the dentists were in accordance with clinical guidelines for management of unerupted third molars.Whereas some of the decisions were in contrary to the guidelines probably due to lack of knowledge about the guidelines among the dentists or Becauseof experience which has influenced their decisions.These conflicting results have hindered the decision making process.

Conclusion

All asymptomatic & pathology free impacted third molars need not be considered forprophylactic removal but should be reviewed periodically.

Keywords

Asymptomatic, Impaction, Wisdom tooth, Asymptomatic, Prophylaxis

Introduction

Generally third molars erupt between 18 and 24 years of age, although there can be vast Differencein eruption time.Approximately in 25% of adults one or more third molars are Absent [1-4] but in most of the elderly patients they remain impacted. The prevalence of Impacted third molars are influenced by age, gender and race. The failure of third molar Eruptionis a very common problem [5-7] and the removal of impacted third molar teeth is Oneof the surgical procedures carried out frequently in the dental clinics.Surgical removal Of impacted third molarmay be associated with certain complications postoperatively; These complications are more common in the mandible than in themaxilla; They may include haemorrhage, alveolar osteitis, nerve damage, delayedHealing, periodontal defects in adjacent tooth and infection. It is not mandatory that allthird molars should be removedeven in the absence of pathological findings, hencepatients need not unnecessarily have to accept harmful consequences associated with the surgery.

Approximately 75% of individuals who undergo regular dental care have their third molar extracted [8].Apart from pathological conditions, other criteria that justify the decision to extract third molars isfor orthodontic, prosthetic or restorative purposes [9, 10].In additions, the risks associated with the surgery are accepted by most of the surgeons, when there is clinical or radiological confirmation of periodontitis, caries, pericoronitis, damagingeffects on second molars [11,12].

Although a number of studies have been reported on third molar extraction, the inconsistent results hinder the decision-making process. This study aims in accessing the decision making of the dentists and understanding the justification for removal or retention ofasymptomatic impacted third molars under various conditions.

Materials & method

This study recruited 100 participants among the dentists of Saveetha Dental College. The participants included 50 Oral & Maxillofacial Surgeons and 50 other speciality dentists.The judgement on removal or retention of asymptomatic impacted third molar under various situations was assessed using a questionnaire which had 15 questions.The various situations

were - asymptomatic impacted third molar in a 18 year old adult, prior to orthodontic treatment to prevent late anterior crowding, pericoronitis, associated with risk of periodontal defects post operatively, fear of second molar caries, risk of root resorption in second molar, riskof development of cyst or tumors, risk of permanent parasthesia, impediment in orthognathicsurgery or prosthetic replacement.The response was calculated in percentage and results were tabulated.Bar graphs were also plotted comparing the response given by the OMS and others for each.

Results

In this study, 98% of the Oral & Maxillofacial surgeons and 55% of other speciality dentisthave the opinion that removal of asymptomatic impacted third molar is not ideal in a 18 year old adult.Whereas 2% of Surgeons and 45% of other speciality dentists believe that prophylactic removal of the impacted third molar is a better decision in this situation.

About 80% of other speciality dentists chose that extraction of the impacted third molar Prior to orthodontic treatment has to be done to prevent late anterior crowding.Whereas 87.5% of the surgeons feel that third molar can be retained as it will not cause anterior crowdingon eruption. 98% of surgeons and 85% of other dentists who participated in this study thinks that asymptomatic impacted third molar should be removed if it is associated withhigh incidence periodontal defect distal to second molars.Whereas 2% of surgeons and 15% of other dentists believe that it can be retained in such condition to prevent further complications.88% of surgeons & 55% of other dentists feel that it is better to retain the asymptomaticimpacted third molar which is associated with healthy periodontium.

About 20% of surgeons & 75% other speciality dentists consider extraction of the impactedthird molar to be the ideal treatment incase of pericoronitis.Whereas 80% of surgeons& 25% of other dentists feel that it is not necessary to remove the impacted third molarto manage pericoronitis. 96% of surgeons & 92% other dentists in this study opted removalof impacted third as the treatment to prevent second molar caries. 100% of surgeons & 98% of other dentists believe that root resorption in relation to second molar can be preventedon removal of the impacted third molars.

In the present study only 37.5% & 15% of the surgeons chose extraction of impacted third molar is better when it is associated with the risk of cyst formation & neoplasm development respectively.About 52.5% of the surgeons & 60% of the other dentists feel that it is better to retainthe asymptomatic impacted third molar as it can cause permanent parasthesia post operativelyin some cases.98% & 52% of the surgeons chose removal of the impacted third molarcan be done if it impedes orthognathic surgery & prosthetic replacement respectively.

The dentists belonging to other specialities showed greater tendency towards extraction of asymptomatic impacted third molars when compared to the surgeons. (Table 1)
Bar graphs were plotted to compare the decisions made in each situation by the surgeons & other dentists. (Fig 1 &2)

Table 1: Decisions made by Surgeons & other dentists

Questions Asymptomatic impacted Third molar	Response	Oral & Maxillofacial surgeons	Other speciality Dentists
In a 18 year old patient	Removal	2%	45%
	Retention	98%	55%
Associated with risk of late anterior crowding	Removal	12.5%	80%
	Retention	87.5%	20%
Associated with higher Incidence of periodontal Defect distal to 2nd molar	Removal	98%	85%
	Retention	2%	15%
Associated with healthy Periodontium	Removal	12%	45%
	Retention	88%	55%
Associated with mild Pericoronitis	Removal	20%	75%
	Retention	80%	25%
Associated with risk of Second molar caries	Removal	96%	92%
	Retention	4%	8%
Associated with risk of Root resorption of second molar	Removal	100%	98%
	Retention	-	2%

Associated with risk of cyst development	Removal	37.5%	75%
	Retention	62.5%	25%
Associated with risk of Neoplasm	Removal	15%	55%
	Retention	85%	45%
Associated with risk of Permanent parasthesia	Removal	47.5%	40%
	Retention	52.5%	60%
Impeding orthognathic Surgery	Removal	98%	93%
	Retention	2%	7%
Impeding denture Construction/implant Placement	Removal	52%	65%
	Retention	48%	35%

Discussion

Tooth impaction has been a common phenomenon nowadays. Tooth impaction is a pathological situation in which a tooth is unable to erupt into its normal functioning position due to lack of space. The impaction can be mesioangular, distoangular; horizontal, transverse or vertically angulated .It is often associated with pain, pericoronitis, root resorption, cystic lesions, etc. However, there is considerable variation in the prevalence and distribution of impacted teeth in different regions of the jaw. Factors affecting the prevalence can be the age-group, timing of dental eruption, and the radiographic criteria for dental development and eruption[13]. According toSwarna et al study, third molar impactions have a mandibular predisposition, and showed a predilection towards females than males. Agenesis of third molars was more common in females than in males and was more common on the right side.The most common pattern of impaction was mesio-angular followed by vertical which is more common on the left side, horizontal which is common on the right side [14].

Mead defined an impacted tooth as a tooth which is prevented from erupting into Positionbecause of malposition, lack of space, or other impediments [15]. Peterson describedimpacted tooth as tooth that fails to erupt into the dental arch within the expected time.Later Farman proposed that impacted teeth are those that are prevented from eruptiondue to a physical barrier within the path of eruption [16]. It should be noted that any normally erupted teeth would have been unerupted or partially erupted at certain stage in the process of eruption.Hence,all unerupted or partially erupted teeth should not be considered as impacted teeth [17]. Impacted third molars may be associated with certain pathological changessuch as infections, dental caries, destruction of adjacent teeth, cysts and tumours. Although impacted third molars do not necessarily cause some of these pathological changes (such as dental caries), the impaction may increase the risk of disease, particularly when oral hygiene is poor.

As the third molars erupt completely into position anytime between 18 to 24 years,it is notideal to extract the asymptomatic impacted third molar at the age of 18.In the present study, 98% of OMS & 55% of other speciality dentists have said the asymptomatic impacted third molar need not be removed.Whereas 45% of other dentists have said that removal is better, as they probably are unaware that a tooth which impacted at 18 years of age can fully eruptby 25 years and also post operatively complications may occur after surgical extractions.

In this study, 87.5% surgeons have chosen retention of asymptomatic impacted third molar preceding orthodontic treatment.In a randomized study carried out by Harradine et al showed that the removal of third molars to prevent late incisor crowding cannot be justified [18]. Southard in his study concluded that the force generated by eruption of third molar is insufficient to significantly affect anterior crowding [19].The National Institute of Clinical Excellence (NICE) in 2000 (20) & the Scottish Intercollegiate Guidelines Network (SIGN) in 1999 reviewed in 2005 (21) did not consider late anterior crowding as a reason to justify the prophylacticremoval of third molars.About 80% of other dentists have opted for extraction of the impacted third molar prior to orthodontic treatment to prevent late anterior crowding.This is probably because they are unaware of the clinical guidelines for management of asymptomatic impacted third molar.

According to SIGN, there is a strong indication for removal of impacted third molar whenit is associated with periodontal disease in relation to second molar. In this study about98% of OMS & 85% of other dentists have opted for removal in such condition.There isa debate about the development of periodontal defect at the distal surface of the second molarsafter extraction of the impacted third molars. Some authors showed improvement of periodontalhealth distal to the adjacent second molar, while others have revealed attachment loss and reduction in level of alveolar bone [22].Only 12% of OMS opted removal, whereas 45% of other dentists chose for extraction of impacted third molar with healthy periodontium preoperatively. This is because they probably lack the knowledge about development of periodontaldefect after removal of impacted third molar.

Not all cases of pericoronitis should be treated with extraction.First episode of pericoronitis, unlesssevere should not be indicated for surgical removal of the third molar[23].About 80% of the OMS in this study are aware about this, but only 20% have opted retention of the asymptomaticimpacted third molar in case of mild pericoronitis. This is again because other specialitydentists are not familiar with the NICE guidelines.

About 96% of OMS & 92% of other dentists in this study have chosen removal of asymptomatic impacted third molar if it is associated with second molar caries.According to SIGN guidelines, there is a strong indication for removal of impacted third molar when there iscaries in the adjacent second molar, which cannot be satisfactorily treated without it's extraction [22].Walmsley et al reported that when second molar is restored but third molar is retained, recurrent caries can develop in the second molar extending to impacted adjacent thirdmolar causing loss of both the teeth [24].Thus prophylactic removal of impacted third molar which is mesioangular in position may be considered to prevent distal caries formation. Dentists who opted retention are not aware that mesioangular type of impactions can causesecond molar caries.

In this study, about 100% OMS & 98% other dentists chose removal of the impacted third molar if it is associated with the risk of root resorption of second molars.According to SIGN guidelines, third molar removal should be considered incase of root resorption of the second molar where it would be due to the third molar [22].Majority of the participants have opted thisdecision.

Around 62.5% of OMS have chosen retention of asymptomatic impacted third molar

whichis associated with risk of developing cysts which is in contrary to the clinical guidelines.This decision is probably opted as the incidence of cyst development on retention of the impacted third molar is rare (1.65%), according to Friedman et al [25].Whereas 75% of other dentists have chosen removal in such condition, possibly because they are not aware about the rareness of cyst development on retention of impacted third molars.

Similarly, tumors developing around the impacted third molar are relatively low (1.16%) [26] and so the fear of neoplasm cannot be considered as the justification for removal of asymptomaticimpacted third molar.About 85% of OMS & 55% of other dentists have given thesame opinion, which is not in accordance to the NICE guidelines. Whereas, 45% of other Dentistshave opted removal as they are again not aware about the rareness of tumors that developwhen impacted third molars are retained.

Incidence of permanent parasthesia after surgical extraction of impacted third molar rangesfrom 0.33 - 1% which is quiet rare. About 52.5% of OMS & 60% of other dentists have chosen retention of the impacted third molar maybe because the conditions where there ishigh risk of nerve injury (deflection of mandibular canal) should be taken into consideration.Whereas 47.5% of OMS opted removal maybe because they are aware that propersurgical method without excessive removal of bone & vertical sectioning of impacted teeth will prevent permanent parasthesia. But 40% of other dentists have opted removal probably because they are not aware that permanent parasthesia can occur postoperatively.

According to AAOMS, there is a view that when an impacted third molar may Complicateorthognathic surgery,then it is reasonable to remove that tooth, provided the risks of complications do not outweigh the benefits [27].About 98% of OMS & 93% of other dentistsin this study have also opted removal, which is in according to the report submitted WithAAOMS.

According to SIGN guidelines, removal of an impacted third molar close to the alveolar surface should be considered preceding denture construction or implant placement.About

52% of OMS & 65% of other dentists have chosen removal as their decision which is in agreementwith the clinical guidelines.Whereas 48% of OMS & 35% of other dentists feel thatprosthetic replacement is not a justification for removal of asymptomatic impacted third molarconsidering the complications which may arise after surgery.

There are no previous questionnaire based study carried out among the dentists about theirdecision on management of asymptomatic impacted third molars.This is a first study of thatkind.It is understood from the results that majority of the OMS have good knowledge aboutthe clinical guidelines for management of unerupted third molar than other speciality dentists.There are some conditions where decisions made by the dentists are not in agreement with the guidelines, probably because their experience influences their decision.The dentists belonging to other speciality lack proper decision making ability & showed greater tendency towards extraction of asymptomatic impacted third molars.Even though they do not have amajorrole in decision making about the management of asymptomatic impacted third molar, they are the ones who are going to refer the patients to a surgeon when they identify anasymptomaticimpacted third molar. Hence, some methodology should be employed forimplementationof clinical guideline on management of asymptomatic mandibular thirdmolar which can improve dentists' knowledge on this topic and their decision making ability.

Conclusion

From this study it is conclusive that general dental practitioners show greater tendency Towardsextraction when compared to Oral & Maxillofacial surgeons.All asymptomatic & Pathologyfree impacted third molars need not be considered for prophylactic removal but Shouldbe reviewed periodically.

Abstract

Chronic kidney disease includes conditions that damage your kidneys and decrease their ability to keep you healthy by doing the jobs listed. If kidney disease gets worse, wastes can build to high levels within the blood.Earlier recognition of chronic kidney disease (CKD) could slow progression, prevent complications, and reduce cardiovascular-related outcomes. However, current estimates of CKD awareness indicate that both patient- and provider-level awareness remain unacceptably low. Many of the factors that are possibly associated with CKD awareness, which could help guide implementation of awareness efforts, have yet to be fully examined.

***Key words**: Chronic kidney disease, cardiovascular, blood, Complications*

Introduction

Chronic kidney disease (CKD) is a public health concern, affecting an estimated 35% of Indian population [1]. CKD is associated with an increased risk of cardiovascular disease and chronic renal failure. Better management of CKD can slow progression of renal dysfunction, prevent metabolic complications, and reduce cardiovascular-related outcomes [2]. Physician awareness of disease is critical for implementation of evidence-based therapies, and patient awareness is a major determinant of adherence to those therapies. Long term hypertension is a risk factor for many diseases, including heart disease, stroke and kidney failure

Awareness of CKD remains unacceptably low, despite recent attempts to increase awareness through dissemination of clinical practice guidelines and recommendations for patients with CKD or its risk factors to providers [3-5], community awareness events such as world kidney day [6,7], and free screening efforts for high-risk individuals like the kidney early evaluation program (keep) [8,9]. Earlier recognition of CKD could lead to slow progression, prevent complications, and reduce cardiovascular-related outcomes; additionally, early referral to nephrologists has been shown to improve outcomes for those who progress to end-stage renal disease.

We examined whether well-known manifestations of kidney disease were associated with greater individual CKD awareness. We hypothesized that participants who exhibited markers of kidney dysfunction for any given level were more likely to have a provider who detected CKD and communicated the individual's CKD status to the participant, resulting in greater individual awareness of CKD.

Materials and Method

A questionnaire based study on 50 individual CKD patients was conducted and compared. To find the epidemiological variations with relation to CKD among the population using a questionnaire based study within Saveetha medical college.

Self-reported sociodemographics (age, gender, race/ethnicity, marital status, social support, primary language, education, and income), access to care (insurance and routine site for medical care), and diagnoses (CKD and Diabetes) were obtained during interviews.

Questions like at which stage where they were diagnosed with ckd and the awareness of the symptoms of CKD such as bone diseases, anemic, heart diseases, edematous lesions were asked in the questionnaire.

Results

The questionnaire based study was conducted among 50 individuals who were either diagnosed with CKD or was a relative to the patient diagnosed with CKD. It was found out that 68% of the patients were diagnosed with chronic kidney disease at earlier stage itself.

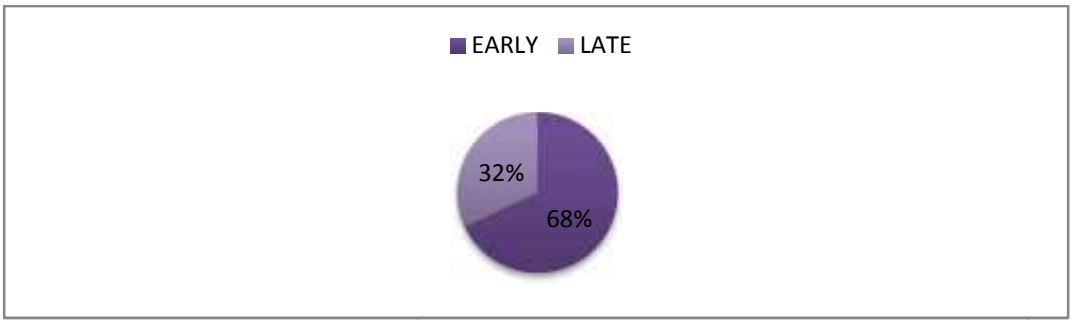

Figure 1: Pie chart depicts the stage at which CKD was diagnosed

When the prevalence risk ratio was conducted, awareness was less in males when compared to females.

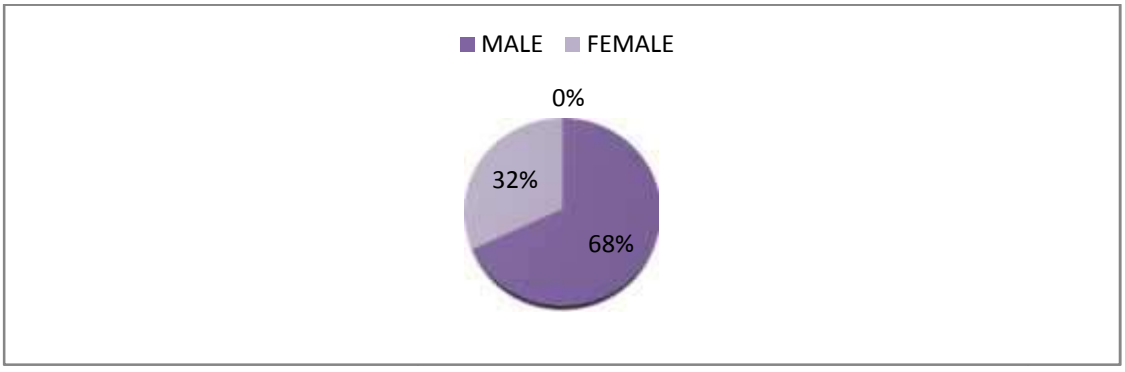

Figure 2: Pie Chart depicts the awareness of CKD in males and females.

Half of the cases of CKD (49.1%) were not associated with any of the measured risk factors of hyper tension, diabetes or HIV.

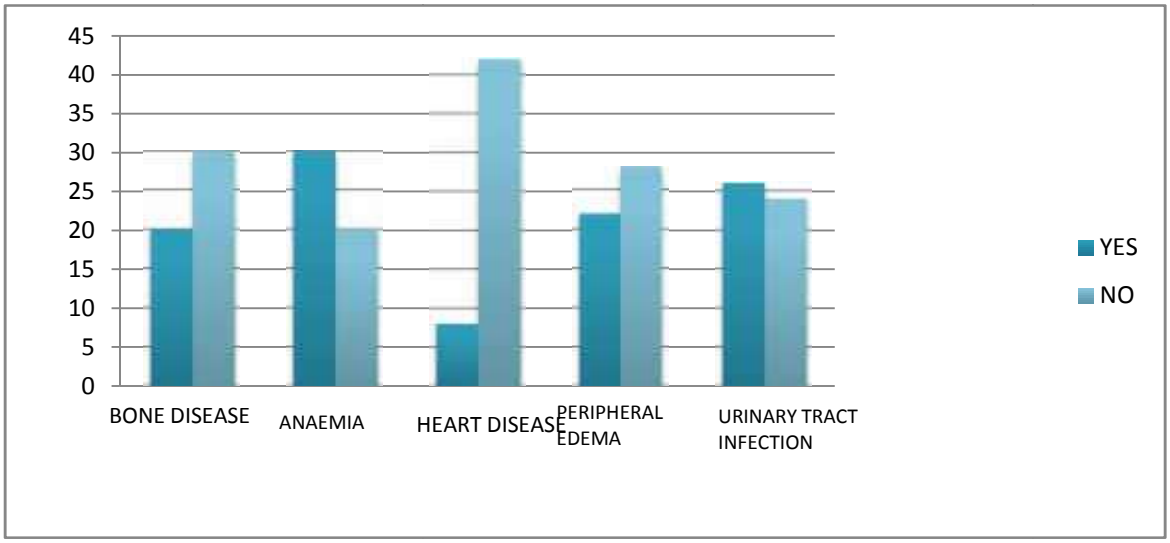

Figure 3: Bar graph depicts the awareness of risk factors associated to CKD

Many patients were aware of the urinary tract infection and anemia due to CKD. But a major amount of patients were not aware that heart, bone diseases and peripheral edema were also symptoms of CKD.

Discussion

Although research among CKD patients has shown that greater knowledge of their condition leads to better clinical outcomes [10,11] little data are available on whether awareness of earlier-stage CKD is associated with better clinical outcomes. There is some evidence that those with higher perceived risk for ckd are more likely to seek information, speak to their doctor about ckd, and get tested [12]. Interestingly, those with the highest and lowest perceived risk were less likely than those with intermediate perceived risk to have controlled blood pressure [13]; for those with the highest perceived risk, psychological factors such as those mentioned above may explain this result. Awareness of CKD status was not generally associated with achieving target blood glucose regardless of diabetes status in the keep study [14], but CKD awareness was associated with lower hemoglobin a1c in a group of primary care patients with diabetes and ckd [15]. Further research is necessary to determine whether—and for whom—CKD awareness leads to better self-management and better clinical outcomes (particularly, decreased hospitalization, cardiovascular events, and/or mortality). Additionally, the possibly negative consequences of CKD knowledge and awareness, including excess worry about risk and decreased quality of life

and depression associated with the diagnosis of chronic disease, should also be explored and weighed against any improvements in clinical outcomes.

Surveys demonstrate high levels of knowledge of diabetes and hypertension as risk factors, with 99% of family practice and internal medicine trainees identifying them as strong risk factors in web-based questionnaires [16, 17]. Minority status, age, and family history of CKD were less well-recognized as risk factors. A survey of Pcps practicing in predominantly African-American communities also revealed that a third of respondents (34.4%) did not consider family history of kidney disease to be associated with increased risk of CKD and 22% did not consider African American race to be a risk factor for development of CKD [18].

Early referral of patients to nephrologists is optimal, but given the relatively small number of practicing nephrologists nationwide, nephrologists cannot exclusively manage all patients with CKD [19]. The awareness of CKD is unacceptably low and knowledge of CKD management is particularly poor among the patients even though the data is very limited. Further exploration of the factors associated with decreased CKD knowledge and the impact of CKD awareness on individual patient outcomes and public health outcomes is necessary to guide awareness efforts moving forward [20].

Conclusion

CKD in its early stages is usually silent and without remarkable symptoms, patients may not be aware of their disease. Even persons who have been identified as having early-stage CKD by evidence of kidney damage or reduced kidney function through regular screening may not understand their diagnosis or recognize the importance of treatment. Better management of CKD can slow the progression of CKD, prevent complications, and reduce cardiovascular-related outcomes.

Beneficial Effects of Murraya Koeinjii inModern Medicine

Vidhya.T.K[1],Anitha Roy[2], Saravana Pandian[3],

Graduate Student[1],Head[2], Department of Pharmacology, Senior Lecturer[3], Department of Orthodontics,

Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Murraya koienjii is also known as curry leaves. Several studies have been done regarding the therapeutic uses of Murraya koienjii. This study is to compile the overall usefulness of this plant. Leaves are used as herb in ayurvedic medicine and it has an anti-diabetic properties. Murraya koeinjii is widely used as a nephroprotective against kidney infirmities in Malaysia. Dementia is a common disorder in older patients, leaves have many beneficial effects, it is used in the management of alzheimers disease and dementia. Girinimbine, a carbazole alkaloid isolated from stem bark is also used in the treatment of breast cancer. Leaves are also used in the growth of hair and helpful for good vision. Pharmacological activities of the plant are activity on heart, anti-diabetic and cholesterol reducing property, anti-microbial activity, anti-ulcer activity, anti -oxidative property, cytotoxic activity, anti-diarrhoea activity, phagocytic activity and many more medicinal values.Being a plant with much therapeutic potential to bring an awareness of this plant.

Keywords: Murraya Koienjii, anti bacterial, anti ulcer, anti oxidative, anti diarrhoea.

Introduction

India is one of the pioneers in the discovery of herbal medicines for the treatment of various ailments. *Murraya koemji*i is an important spice in Asia. It belongs to family *Rutaceae*. A few metres high shrub; the main stem, dark green to brownish, with numerous dots on it; its bark can be peeled off longitudinally, exposing the white wood underneath; the girth of the main stem is 16 cm(1). Leaves, exstipulate, bipinnately compound, 30 cm long, each bearing 24 leaflets, having reticulate venation; leaflets, lanceolate, 4.9 cm long, 1.8 cm broad, having

0.5-cm-long petiole(2). Murraya koeinjii leaves are used as flavouring, condiment, and folk medicine for the treatment of various metabolic and infectious disease(3,4).It is an antiemetic, anti-diarrhoeal, febrifuge and blood purifier, phytochemical screening of Murraya koeinjii leaves revealed the presence of some vitamins(A,B), carbazole alkaloid(kurryam, koenimbine and koenine) , trepenoids, phenolic compounds, and mineral contents such as calcium, iron, zinc and vanadium. Besides it has no side effects and can cure the patient for any kind of infectious disease. (5) The green leaves are stated to be eaten raw for curing dysentery, and the infusion of the washed leaves stops vomiting. Curry leaves are also used in calcium deficiency. Its nutritional value benefits both the young and the old alike(6). Women who suffer from calcium deficiency, osteoporosis etc. can find an ideal natural calcium supplement in curry leaves. Fresh juice of curry leaves, with lime juice and sugar, is an effective medicine in the treatment of morning sickness, nausea and vomiting (7). In the present review, Murraya koeinjii was chosen since it is one of the most widely acclaimed remedies for the treatment of many disease.

Figure 1: Inflorescenceand Leavesof MurrayaKoenjii

Traditional Uses

Fresh leaves, dried leaf powder, and essential oil are widely used for flavouring soups, curries, fish and meat dishes, eggs dishes, traditional curry powder blends, seasoning and ready to use other food preparations. The essential oil is also utilized by soap and cosmetic aromatherapy industry.16 Curry leaves are boiled with coconut oil till they are reduced to blanked residue which is then used as an excellent hair tonic for retaining natural hair tone and stimulating hair growth. It is traditionally used as a whole or in parts as antiemetics, antidiarrheal, febrifuge, blood purifier, antifungal, depressant, anti-inflammatory, body aches, for kidney pain and vomiting.

Phytochemistry

Mature leaves contains 63.2 % moisture, 1.15 % total nitrogen, 6.15 % fat, 18.92 % total sugars, 14.6 % starch, 6.8 % crude fiber, ash 13.06 %, acid insoluble ash 1.35 %, alcohol soluble extractive 1.82%, cold water (20˚C) extractive 27.33% and a maximum of hot water soluble extractive 33.45%. 30 Constituents that have been stimulated the most interest includes a wide range of carbazole alkaloids, essential oil and carotenoids. The following major group of bioactive constituents summarizes the constituents of murraya.

Carotenoids

Leaves contain 9744 ng of lutein, 212 ng of α-tocopherol and 183 ng of carotene/g of fresh weight. 31 21.4 mg/100 g of total carotene, 7.1 mg/100 g of β-carotene is reported by Bhaskaracharyet. al. 32 E. Siong Tee has reported 14570-µg/100 g of total carotenoids in leaves as measured by HPLC. Out of total carotenoids, lutein content was 5252 and β-carotene content was 9328 µg /g. 33

Carbazole Alkaloids

Leaves: Tachibana et.al has isolated 8, 10’-{3,3’,11, 11’-tetrahydro-9,9’ dihydroxy- 3,3’,5, 8’-tetra methyl –3,3’-bis (4-methyl-3-pentenyl)}bispyrano (3,2 a) carbazole (a dimericcarbazole alkaloid) from methylene chloride Vandana Jain International journal of ayurvedic & herbal medicine 2(4) aug . 2012(607-627) 609 extract of M. koenigii leaves together with six known alkaloids; koenimbine, O- methyl murrayamine, Omethylmahanine, isomahanine and bismahanine and bispyrayafoline. 34,35 From dried leaves glycozoline,36 1-formyl –3 methoxy- 6-methyl carbazole and 6, 7- dimethoxy- 1- hydroxy- 3-methyl

carbazole 37 was isolated. Koenigine, koenine, koenidine and (-) mahanine were isolated from acetone extract of leaves.Form the hexane extract of leaves Joshi et.al has isolated mahanimbine, isomahanimbine, koenimbidine and murrayacine.Isomahanimbicine was isolated form petroleum ether extract of leaves of M. koenigii specifically collected in the month of February 38. Euchrestine B, mahanine, mahanimbicine, mahanimbine 35, bismurrayafoline E 35,40, mahanimbicine, bicyclomahanimbicine 41, cyclomahanimbinebicyclomahanimbine, mahanimbidine 42, mukonicine 43, 8, 8"-biskoenigine, new binary carbazole alkaloid along with its monomer koenigine 44 and a minor alkaloid mahanine 45 were identified and isolated from leaves of M. koenigii. Gupta et.al has reported the presence of murrayanine (0.32%), glycoside scopolin (0.25%), free glucose (3.5%) and ash (10.4%) 46. Arial part is reported to contain murrayanine and 8,8" biskoenigine 47. Patroleum ether extract of leaves was used to isolate carbazole alkaloids, mahanimbine(3,5- dimethyl-3-(4-methylpent-3-enyl)-11H-pyrano[5,6-a] carbazole)48 . Methanolic extract of M. Koenigii was subjected to qualitative thin-layer chromatography and HPLC using different solvent system by Gupta et.al. Spectral analysis (IR, 1H NMR, 13C NMR and MS) was carried out to establish the structure. The structures of these 6-bioactive compounds confirmed as carbazole alkaloids- Mahanimbine, Girinimbine, Isomahanimbine, Murrayazoline, Murrayazolidine, and Mahanine, by the spectrometric data. 49 Stem: From alcohol extract of stem bark Saha et.al has isolated koenigine- quinone A and koeniginequinone B, structures were established as 7- methoxy- 3 methyl carbazole- 1,4-quinone and 6, 7-dimethoxy-3-methyl carbazole-1, 4- quinone respectively 50. 9-carbethoxy-3-methyl carbazole and 9- formyl –3- methyl carbazole were identified form M. koenigii by Chakrabortyet. al 51. Me- 2- methoxy carbazole –3- carboxylate and 1- hydroxy –3- methyl carbazole were isolated form stem bark52. Mukonal, a probable biogenetic intermediate of pyranocarbazole alkaloid was detected in stem bark.53 From stem bark Murrayazolinol (a minor carbazole alkaloid)54, mahanimbinol55 , murrayazolidine56, 57, murrayacinine58, mukonidine59, murrayazolinine60, murrayanine, girinimibine and mahanimbine61, girinimbinol and mahanimbilol62 (possible biogenetic precursors of girinimbine and mahanimbine) has also been identified and isolated. Roots: Murrayanol, murrayagetin, marmesin- 1"- O- rutinoside were isolated form root extract63. Three monomeric and five binary carbazole alkaloids named mukoenine- A, -B and C and murrastifoline –F. bis – 2- hydroxy3- methyl carbazole, bismahanine, bi koeniquinone- A and bismurrayaquinone A were isolated form root and stem bark64. Koenoline (1- methoxy-3-hydroxy methyl carbazole) was isolated form the root bark65, Mukoline, mukolidine were

isolated form the benzene extract of roots63. Roots were also found to contain girinimbine39, 66. Seeds: Mahanimbine, girinimbine, koenimbine, isomahanine and mahanine were isolated form seeds of M. koenigii from Marassana, Sri Lanka 67. 2- methoxy-3- methyl carbazole was isolated form petroleum ether extract of seeds68 . Mandal et.al isolated three bioactive carbazole alkaloids, kurryam (I), Koenimbine (II) and koenine (III) with structural confirmation with 2D-NMR spectra69 Fruits: Mahanimbine and koenimbine were isolated from petroleum ether extract of fruits 38,70. Isomahanine and murrayanol were isolated form fruits by Reischet. al along with five previously reported carbazole alkaloids mahanimbine, murrayazolidine, girinimbine, koenimbine and mahanine71. Coumarin: Indicolactone, anisoalctone and 2', 3' epoxy indicolactone (a furocoumarin lactone) were isolated from the seeds. This represents the first furocoumarin with a mono terpenoid lactone chain in the genus Murraya72. Vandana Jain International journal of ayurvedic & herbal medicine 2(4) aug . 2012(607-627) 610 Adebajoet. al has reported xanthotoxin, isobyaknagelicol, byakangelicol and isogosferol as minor furocoumarins in seeds of M. koenigii73. Isoheraclenin, isoimperatonin, oxypeucedanin, isopimpinellin and bergaptan were isolated form seeds of Marassana village, Sri Lanka, suggesting it as a new chemical race74. A new coumaringalactosidemarmesin- 1'-O-β-D-galactopyranoside, osthol and umbelliferone were isolated form ethanol stem bark extract75 . 3- (1,1- dimethyl allylxanthyletin) was isolated form petroleum ether extract of stem bark of M. koenigii76.

Pharmacological Activities

Antifungal Activity

Acetone extract of M. koenigii is active against Aspergillus niger, benzene extract is most active against Alternaria solani and Helminthosporium solani and ethanol extract is active against Penicillum notatum(8)

Antioxidant Activity

Antioxidants stop unwanted oxidation in the body, which involve the formation of free radicals and further deteriorate the condition of the body .(9) Reactive oxygen species (ROS), causing damage to DNA, proteins and lipids, have been associated with carcinogenesis, coronary heart disease and many other health problems. . The most commonly added antioxidants are synthetic phenols, such as butylated hydroxy toluene (BHT) and butylated hydroxy anisole (BHA). Their safety however is doubtful. (10).

Cytotoxic Activity

Alkaloid Koenoline isolated from the root bark of M.koenigii is found to exhibitcytotoxic activity against KB cell culture system (11). Carbazole alkaloids isolated from the stems are found to effects the growth of the human leukemia cell line HL-60. Mahanine, Pyrafoline-D and murrafoline-I (Carbazole alkaloids) showed significant cytotoxicity against HL-60 cells and also induced loss of mitochondrial membrane potential.

Radiation Protection Activity

The effect of 4 Gy gamma radiation 30 min after the last injection of 100 mg/kg of methanolic extract of M. koenigii for 5 consecutive days was observed on adult Swiss albino mice. The extract itself increased the glutathione and enzymes levels, whereas radiation significantly reduced all values. Pretreatment with the extract reduced lipid peroxidation rate induced by radiation. The result demonstrated that M. koenigii leaves possess good antioxidant activity in vitro and are able to protect against radiation-induced depletion in cellular antioxidants152 Themethanolic extract showed protection against gamma radiation and cyclophosphamide-induced chromosomal damage in Swiss albino mice at a single dose of 100 mg/kg body weight153

Antiulcer Activity

Anti ulcer activity was observed using aqueous extract at doses of 200 and 400 mg/kg. It produced significant inhibition of gastric lesion induced by non-steroidal anti-inflammatory drugs and pylorus ligation-induced ulcer. The extract reduced ulcerative lesion, gastric volume and free and total acidity but raised the pH value of gastric juice in pylorus ligation model. The results obtained suggested that the extract possesses significant antiulcer activity154.

Antidiarrhoeal Activity

Bioactive alkaloids, kurryam and koenimbine obtained from fractionated n-hexane extract of the seeds of M. koenigii were found to exhibit inhibitory activity against castor oil-induceddiarrhoea and prostaglandin E2-induced enteropooling in rats in charcoal meal test in

Wister rats, these compounds were found to exhibit significant reduction in gastrointestinal motility(13). The bioassay guided fractionation of the n-hexane extract of the seeds of M. koenigii resulted in the isolation of three pure compounds of bioactive carbazole alkaloids, kurryam, koenimbine and koenine(14,15). Of the three compounds kurryam and koenimbine exhibited significant inhibitory activity against castor oil-induced diarrhoea and PGE2-induced enter pooling in rats. The compounds also produced a significant reduction in gastro-intestinal motility in the charcoal meal test in Wister rats (16).

Antiulcer Activity

Antiulcer activity of aqueous and ether extracts of M. koenigii was studied in reserpine induced gastric ulcer model in albino rats. Extracts were effective in gastric ulceration and suggested as protective as ranitidine (17). Crude aqueous extract of leaves showed anti-ulcer activity which was evaluated by using models of acute gastric lesions induced by ethanol induced, aspirin induced, cold restrain stress and pylorus ligation in rats(18) Animals were pretreated with doses of 200 mg/kg and 400 mg/kg of aqueous extract which showed efficient reduction in lesion index, total affected area and percentage of lesion in comparison with control group in the ethanol induced, aspirin induced, cold restrain stress induced ulcer and pylorus ligation models. These observations provide a confirmation about aqueous extract of leaves of M. koenigii can act as good anti-ulcer drug (19) .

Vasodilating Activity

Crude aqueous leaf extract of M. koenigii was prepared which showed a dose dependent negative chronotropic effect on cardiovascular system of frog heart preparations which might be due to its direct actions on the heart and blood vessels. Potassium ion concentration was also found to be very negligible by flame photometry, indicating no involvement of potassium ions.(20) The aqueous leaf extract possesses vasodilatory effect which is independent of muscarinic, histaminergic and ß-adrenergic receptor as it increased the number of drops/minute in frog hind limb perfusion experiment and also does not possess α-adrenergic receptor antagonistic activity. The aqueous leaf extract showed significant effect at concentration of 1 mg/ml (21). Crude ethanolic extract of fresh leaves of M. koenigii showed dose dependent positive ionotropic effect on an isolated frog heart. The response to M. koenigii 62.5 - 1000 µg was not affected in either way by theophylline, imidazole, propanolol and sildenafil. The changes in potassium and sodium concentration did not alter.

The result suggested that M. koenigii induced positive ionotropic effect possibly by increasing availability of calcium from extra cellular sites (22)

Hypocholesterolemic Activity

Hypocholesterolemic activity was checked in aged mice, which was done by using crude ethanol extract of plant leaves of M. Koenigii. The experiment was confirmed by observing a decrease in cholesterol level in dose dependent manner in aged mice. The dose of 500 mg/kg was found more efficient than the 300 mg/kg and was comparable with the standard cholesterol reducing agent, Simvastatin. Carbazole alkaloids a major phytochemical constituent of plant found to have lipid lowering etc (23) .

Analgesic and Antinociceptive Activity

The methanolic extract of leaves showed analgesic effect in hot plate model and formalin induced paw licking response in mice. The activity might be linked to the processes involved in the prevention of sensitization of nociceptors, down regulation of the sensitized nociceptors or blockade of the nociceptors at peripheral and central levels. Methanol extracts were taken at different concentrations, viz. 100mg/ml, 200mg/ml and 400 mg/ml. Among these 400 mg/ml showed prolific results (24) .

Antidiabetic Activity

Curry leaves are rich in many minerals and trace minerals such as Iron, zinc and copper. Minerals found in curry leaf extract are important for maintaining normoglycemia, or the normal glucose content of the blood (25). This is done by the activation of pancreatic beta cells, which are responsible for the creation of insulin. While the nutrients in curry account for only about 1 to 2 percent of the required daily intake for these elements, they are bioavailable, or readily usable by the body. Therefore, the researchers suggested that curry leaves may be useful for the management ofdiabetes.

Effect on Dental Caries

Feeding of murraya leaf extract in golden hamsters showed lower caries scores compared to control group128. Murraya extract or isomahanine, murrayanol and mahanine incorporated in foods (such as candies, biscuits, cakes, chewing gums, juices) showed 86.2% inhibition of methyl suphydral formation by cultured Fusobacterium nucleatum 126. M. koenigii leaf extract containing mahanin, isomahanin or murrayanol as active ingredient formulated in

toothpaste, was found to be useful as oral disinfectant to protect against dental caries and periodontal disorders. They are also effective against Streptococcus mutans and Porphyromonas gingivalis.

Anticancer Activity

Koenoline isolated form root bark exhibited cytotoxic activity against the KB cell culture test system98. 9- formyl-3 methyl carbazole displayed weak cytotoxic activity against both mouse melanoma B 16 and adriamycin resistant P 388 mouse leukemia cell lines51. The effects of extracts of M. koenigii in in-vitro (short term incubation method and in-vivo (Dalton's ascitic lymphoma (DAL) anticancer models have been evaluated in male Swiss albino mice. DAL cells were injected intraperitoneally (106 cells) to the mice125. The anticarcinogenic potential of curry leaf using benzo (a) pyrene induced fore stomach and 7, 12 dimethyl benz (a) anthracene (DMBA) induced skin papillomas was studied. Chemo protective responses were measured as decrease in tumor burden (papillomas/mouse) and % of tumor bearing animals in both the models. Increase in level of acid soluble sulphydral compounds, glutathione S- transferase and DTdiaphorases were also measured. Antioxidant parameters (reduced glutathione, Super Oxide dismutase, catalases, glutathione peroxidase and glutathione reductase) were also elevated131. The in-vitro anti-tumour promoting activity and antioxidant properties of Girinimbine isolated from the stem bark of Murraya koenigii was studied by Yih et.al. The in vitro anti-tumour promoting activity of girinimbine was determined by measuring the percentage inhibition of induced early antigen (EA) of EBV on the surface of Raji cells132 M. koenigii has been found to induce apoptosis in human myeloid cancer cell (HL-60). Results shows that mahanine down-regulates cell survival factors by activation of caspase-3 through mitochondrion-dependent pathway, and disrupts cell cycle progression133 . Another study reported that mahanine, purified from the leaves of M. koenigii , has a dose- and time-dependent antiproliferative activity in acute lymphoid (MOLT3) and chronic myeloid (K562) leukemic cell lines and in the primary cells of leukemic and myeloid patients, with minimal effect on normal immune cells including CD34 (+) cells134.

Conclusion

Murraya koenjii have an significant anti-stress level.Extract from various parts of curry leaf have numerous medical applications, modern drugs are developed after extensive investigation of its bioactivity, and its action, pharmacotherapuetics and toxicity.crudeorganic

extracts of leaves of Murraya Koenigii have some pharmacological activities and found to possess anti-diabetic, cholesterol reducing property, anti-diarrhea activity, cytotoxic activity antioxidant property, antiulcer activity antimicrobial, antibacterial potential and many more usefulmedicinal properties. Murraya koemjii is a rich source of biologically active carbazole alkaloids which would attract the attention of chemist and pharmacologist and plays a significant role in future research in medical science. Keeping in view the tremendous pharmacological activities and wealth of literature available, M. koenigii may be utilized to alleviate the symptoms of variety of diseases as evident form the pre-clinical data. The available literature and wide spread availability of M. koenigii in India thus makes it an attractive candidate for further pre-clinical and clinical research.

Biodentine as a Pulpotomy Agent – A Review

Akshay Satwik T[1], Madhusudan Vasantharajan[2], Sindhu Ramesh[3]
Graduate Student[1], Senior Lecturer[2], Department of Pedodontics, Professor and Head[3],Department of Conservative Dentistry and Endodontics,
Saveetha Dental College , Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

The purpose of this text was to review the clinical applications of biodentine as a pulpotomy agent within the medical specialty practice.Biodentine may be a calcium-silicate primarily based material that has drawn attention in recent years and has been advocated to be employed in varied clinical applications, like root perforations, apexification, resorptions, retrograde fillings, pulp capping procedures, and dentin replacement. There has been sizeable analysis performed on this material since it's launching; but, there's scarce range of review articles that collates info and knowledge obtained from these studies. the aim of this text was to review the clinical applications and blessings of biodentine within the medical specialty practice. Electronic search of English scientific papers from 1992 to 2015 was accomplished exploitation saloon master's degree program. the subsequent search terms used were clinical applications, biodentine, medical specialty dental medicine, children, advantages, dentin substitute, pulp medical care, root filling, and tooth repair. because of its major blessings and distinctive options additionally as its ability to beat the disadvantages of alternative materials, biodentine has nice potential to revolutionize the various aspects of managing each primary and permanent in odontology additionally as operative dental medicine.

Key Words:*Clinical applications,Biodentine,medical specialty dental medicine,pulpotomy , infections*

Introduction

Pulpotomy

Pulpotomy may be a technique that has been accustomed treat primary teeth of that the requirement for additional and additional new materials isn't ending particularly within the field of dental medicine. varied materials are developed, tested and standardized to get most profit permanently clinical performance. One such new material is that the latest bioactive calcium-silicate primarily based material (biodentine), that was recently introduced by Septodont Company and will conciliate high mechanical properties with glorious biocompatibility, additionally as a bioactive behavior (1).

Biodentine may be a calcium-silicate primarily based material that has drawn attention in recent years and has been advocated to be employed in varied clinical applications, like resorptions , retrograde fillings ,root perforations, apexification, pulp capping procedures, and dentine replacement. Biodentine may be a new bioactive cement, kind of like the wide used MTA (1). Biodentine has many blessings that embody smart protection ability, adequate compressive strength, and short setting time, which offer a major clinical advantage over alternative comparable materials (2,3). it's biocompatible and conjointly shows bioactivity (4,5).

The commercialised tricalcium salt of biodentine is totally different from the same old dental atomic number 20 salt “Portland Cement” materials. The producing method of the active biosilicate technology eliminates the metal impurities (such as aluminates and alternative impurities) seen within the “Portland Cement” atomic number 20 silicates. Therefore, the mechanical properties area unit improved in biodentine by dominant the purity of the atomic number 20 salt through this Active Biosilicate Technology. Therefore, it's been developed and made with the aim of transferral along the high biocompatibility and bioactivity of atomic number 20 silicates, with increased properties, that build it additional distinctive than the other atomic number 20 silicate-based materials (2-5).

Biodentine is out there as powder in an exceedingly capsule and liquid in an exceedingly measuring instrument. There area unit 2 sorts of boxes out there within the market. Box is containing fifteen capsules & fifteen single-dose containers and another smaller box that contains solely five capsules & five single-dose containers (4)The powder is principally

composed of tricalcium salt (main core), dicalcium salt, carbonate, and iron chemical compound additionally as zirconia because the radiopacifier. The liquid contains water, salt (as setting accelerator) and a changed polycarboxylate (as superplasticising or water reducing agent) (5).

Biodentine was developed supported the foremost biocompatible chemistry out there for dental materials: atomic number 20 salt, which might set within the presence of water [5]. The atomic number 20 salt can act with water resulting in the setting and hardening of the cement. This association method can turn out hydrous atomic number 20 salt (CSH) gel. As a part of its chemical setting reaction, hydroxide is additionally shaped (5) in contact with phosphate ions, it creates precipitates that match hydroxyapatite (6).

This dissolution method happens at the surface of every grain of atomic number 20 salt. The non reactedtricalcium salt grains area unit enclosed by layers of CSH gel, that area unit comparatively impervious to water, thereby retardation down the results of any reactions. Gradually, the CSH gel fills within the areas between the tricalcium salt grains. Later on, the hardening method results from the formation of crystals that area unit deposited in an exceedingly concentrated resolution (6).

Biodentine attracted attention within the field of dental medicine because of its quick setting time, high biocompatibility, high compressive strength, glorious protection ability, and simple handling additionally as its versatile usage in each dental medicine repairand restorative procedures while not inflicting any staining of the treated teeth [4-6,10]. However, it's conjointly been well-tried that biodentine has a superb antimicrobial properties because of its terribly high hydrogen ion concentration (pH=12). additionally to it, it's rather more value effective as compared to similar materials (7).

Many in vivo and in vitro studies support its bioactivity additionally as its triple-crown performance in several clinical applications(8).On the opposite hand, all the out there clinical studies and case reports unconcealed glorious results for its use in human primary teeth(9).

Due to its improved material properties (short setting time, higher mechanical properties, and straightforward and technology use) additionally as its ability to beat the drawbacks of the

many alternative materials, biodentine could be a stimulating and promising various to the present materials for dentin-pulp advanced regeneration. Biodentine has the potential of creating major contributions within the field of dental medicine by maintaining the teeth in an exceedingly healthy state through various exciting clinical applications (9).Therefore, biodentine guarantees to be one in every of the foremost versatile materials of this century within the field of dental medicine.(10).

The purpose of this text was to review the clinical applications and blessings of biodentine within the medical specialty practice. the garland pulp has been affected or infected by dental caries or traumatized, whereas the radicular pulp remains healthy (10).

Clinical Applications OfBiodentine

Biodentine individuation not solely lies in its innovative bioactive and "pulp-protective" chemistry, however conjointly in its universal application on each crown and root. In the space of the dental crown, it is indicated for pulp capping, treatment of deep unhealthy lesions exploitation the sandwich technique,pulpotomy and conjointly as temporary enamel restoration or permanent dentine replacement.[2] Its use in root includes managing perforations of forking, external and internal reabsorption, apexification and retrograde root canal obturation. In addition to that, it may be used conjointly as bone substitute material for implant stabilization. On the alternative hand, biodentine isn't suggested in massive or esthetic build-ups.(11-15).

BiodentineAs A Pulpotomy Agent

Pulpotomy is another wide used important pulp medical care methodology within which biodentine is advocated to be used .This treatment methodology is that the most often accepted clinical procedure in medical specialty dental medicine once the garland pulp tissue is inflamed and a right away pulp capping isn't an appropriate possibility (15).

In comparison to formocresol in primary teeth pulpotomy, biodentine may be a regenerative material that maintains pulp vitality whereas formocresol may be a devitalizing agent. However, biodentine needed less time for the pulpotomy procedure .whereasformocresol acts solely as dressing material, that desires a restorative material to seal the pulp chamber, biodentine acts at the same time as each dressing and filling material .Thus,

biodentineeliminates the requirement for a filling material within the pulp chamber of pulpotomized teeth. whereasformocresol needs 3–5 minutes application before the cotton pellet is removed, with biodentine the pulp chamber is crammed right away . Moreover, throughout the removal of formocresol-soaked cotton pellet, there's a clear stage of the cotton fibers adhering to clot, leading to reoccurrence of hemorrhage. This doesn't occur with biodentine because it is applied directly while not cotton pellet(16).

In 2012, Shayegan investigated the inflammatory cell response and arduous tissue formation when biodentine pulpotomy in primary pig teeth. when ninety days, they found that the pulp tissue was traditional with none signs of inflammation and nine out of ten teeth showed thick calcification beneath the pulpotomy website. They all over that biodentine has bioactive properties, encourages arduous tissue regeneration, and provoke no signs of moderate or severe pulp inflammation response .

In support to the aforesaid favorable biological results, Marijana , all over that the therapeutic effects of biodentine when important pulp medical care in Vietnamese pigs area unit favorable. Biodentine has the potential of creating major contributions to maintaining pulp vitality in patients judiciously chosen for pulpotomy treatment.Therefore, this distinctive material could be a stimulating various to the present materials for dentin-pulp advanced regeneration.

A survey of the out there literature shows that there area unit nonetheless few revealed case reports and clinical trials with several non-published in progress clinical trials that embody the usage of biodentine in pulpotomy.All these studies showed biodentine as a good and promising various for the present pulpotomy medicaments.

In multiple case reports, Lavaud , showed a triple-crown results of biodentine with none clinical or imaging symptoms once it's used for primary teeth pulpotomy (9 months of follow up), indirect capping on a hypomineralized molar (12 months of follow up), and apexogenesis(14 months of follow up). In another revealed case report, Villat et al. performed a partial pulpotomy in AN immature second right tooth of a 12-year-old patient .After vi months, the patient didn't report any pain or complains on the observation amount. moreover, the authors detected homogenous dentin bridge formation additionally as continuation of root

development .Accordingly, they commented that quick favorable pulpal response render this material an appropriate alternative compared to alternative materials.

Recently at the twelfth Congress of European Academy of medical specialty dental medicine (EAPD) in Polska, Rubanenko, given their preliminary results of comparison biodentine versus formocresol as dressing agents in pulpotomized primary molars.They incontestable a hit rate of 100 percent for biodentine whereas that of formocresol was ninety four .Additionally, Cuadros confirmed these attention-grabbing preliminary results of biodentine in humans and stressed that biodentine appears to be a promising various to be used in pulpotomies of primary molars with 100 percent clinical and photography success when vi months of follow up .On the opposite hand, Rajasekharan, given the results of their randomised management run and showed clinical additionally as photography success in ninety four, 73% of biodentine treated teeth . They all over, “there was no vital distinction between the new product biodentine as compared to the well-known merchandise (mineral oxide combination (MTA) or Tempophore)” .In evaluating this preference dental medicine material in kids amongst Flemish medical specialty dentists, Vandenbulcke, found that biodentine was the foremost most well-liked pulpotomy material in each primary and immature permanent teeth .

Nowicka , studied the response of Biodentine direct pulp-capping in twenty eight caries-free inframaxillary and jaw permanent intact human molars scheduled for extraction for dental medicine reasons when mechanical exposure. when vi weeks, the teeth was extracted, stained with hematoxylin-eosin. They found majority of specimens showing an entire dentinal bridge formation ANd an absence of inflammatory pulp response. Layers of well-arranged odontoblast-like cells and odontoblast were found to create hollow dentin beneath the osteodentin. They conjointly found no statistically vital variations between the Biodentine and MTA experimental groups(15-16).

Han and Okiji compared Biodentine and white ProRoot MTA in terms of Ca and Si uptake by adjacent passage dentine and ascertained whereas each materials shaped tag-like structures, dentine component uptake was additional outstanding for Biodentine than MTA.The same authors in another study showed higher atomic number 20 unharness for Biodentine as compared with MTA. The tag-like structures shaped were composed of Ca and P-rich and Si-

poor materials.(17). Laurent et al. evaluated its genotoxicity, toxicity, and effects on the target cells' specific functions and located that it didn't have an effect on the pulp embryonic cell specific functions like mineralization, additionally as expression of albuminoid I, dentin sialoprotein, and Nestin.

PérardM , assessed the biological effects of Biodentine is employed in pulp-capping treatment, on pseudo-odontoblastic and pulp cells. They conjointly evaluated the results of Biodentine and MTA on organic phenomenon in civilized spheroids, and located Col1a1 expression levels (responsible for matrix secreton) were slightly lower in cells civilized within the presence of MTA than in those civilized within the presence of Biodentine and also the management cells. They all over that each Biodentine additionally as MTA area unit each appropriate for pulp-capping (18).

VillatC , performed partial pulpotomy exploitation Biodentine in AN immature second right inframaxillary tooth and incontestable a quick tissue response each at the pulpal and root dentin level with formation of a radiopaque bridge at intervals 3-6 months. They advised the utilization of tricalcium salt cement ought to be used as a conservative intervention within the treatment of symptomatic immature teeth (19).

Biodentine Used As Pulp Capping Material

Biodentine was conjointly used as direct pulp capping material. BiodentineTM showed:

• a superb tolerance.

• the flexibility to save lots of pulp vitality even in tough cases: the vitality take a look at was positive at every recall.

Moreover, Biodentine is employed in direct pulp capping indications with an honest success rate .it's necessary to underline that BiodentineTM was employed in contact with pulp tissue in an exceedingly patient older than twenty one and maintained the pulp alive.

BiodentineAs A Dental Repair Material

The dental medicine indications of Biodentine area unit kind of like the same old atomic number 20 salt primarily based materials, just like the Portland cements (i.e. ProRoot MTA). this sort of product is already well documented.

Several physical, chemical and biological properties area unit comparable as summarised within the presymptomatic section. However, Biodentine has some options that area unit superior to MTA.

- Biodentine consistency is best suited to the clinical use than MTA's.
- Biodentine presentation ensures a higher safety and handling than MTA.
- Biodentine doesn't need a 2 step obturation as within the case of MTA. because the setting is quicker, there's a lower risk of microorganism contamination than with MTA.

Adding to its ability to be used as dentine substitute, Biodentine may safely be used for every indication wherever dentine is broken . Therefore, its a bonus for the practician and also the patient (20-25).

The tolerance and effectuality of BiodentineTM in vi dental medicine procedures, when three months and when a pair of years follow-up is in progress:

- Direct pulp capping following unhealthy pulp exposure
- Direct pulp capping following dental trauma/injury to healthy pulp (partial pulpotomy)
- Repair of perforated root canals and/or pulp chamber floor
- Retrograde dental medicine surgery.
- Pulpotomy in primary molars
- Apexification .

Conclusion

The clinical applications of biodentine material are mentioned. Biodentine is a superb material with countless qualities needed of a perfect material. The necessary applications of biodentine in medical specialty dental medicine embody dentin substitute, pulp capping, pulpotomy, apexification, and repair material of perforation and reabsorption additionally as root finish filling material. It is another to formocresol in pulpotomy thanks to the tissue irritating, cytotoxic and agent effects of formocresol that area unit resolved with biodentine. However, it is another to hydroxide or MTA in pulp capping, pulpotomy, and apexification as a result of biodentine is extremely triple-crown within the formation of a dentin bridge that's

quicker and thicker with lesser defects. whereas it's stronger automatically, less soluble and produces tighter seals than hydroxide biodentine conjointly avoids the drawbacks of MTA, i.e. extended setting time, tough handling characteristics, high cost, and potential of discoloration.Accordingly, biodentine could be a stimulating various to the present materials for dentin-pulp advanced regeneration (26).

Due to its major blessings and distinctive options additionally as its ability to beat the disadvantages of alternative materials, biodentine has nice potential to revolutionize the various aspects of managing each primary and permanent in odontology additionally as operative dental medicine. On the opposite hand, any studies area unit required to increase the long run scope of this material relating to the clinical applications."(27).

Abstract

The materials generally used for restoration like amalgam, composite etc. are considered as bio hazardous materials. These materials are manufactured with the aim to be insoluble and stable. The acrylic components of composite material is also toxic enough to cause systemic problems. Some of the dental restorative materials can cause harm to the patients and dental personnel. It can cause allergic contact dermatitis ,conjunctival symptoms and asthma. Once the environmental pH changes, the changes in the other parameters causes corrosion and abrasion can allow the bacteria to use the mercury in amalgam and toxicate it. The minute components mixed with these materials leach out of permanent restorative material and tend to cause toxic reactions.

Key Word:*materials, dentistry, biohazards, infection, prevention*

Introduction

A biological agent or infection that constitutes a hazard to human or the surrounding environment is called a biological hazard.There are atleast 193 important biological agents that show infectious allergenic , toxic or carcinogenic activities in the working population .Toxic substances enter our body through absorption , ingestion , inhalation and injection . Absorption can take place through the skin or eyes causing burns , sores , ulcer and other infections . Dentists and dental patients maybe exposed to variety of microorganisms via blood or oral or respiratory secretions[1] the microbes penetrate the body through a cut on the skin while performing either a medical procedure , or a dental procedure . The biological hazards are established by infectious agents of human origin and embrace viruses, bacterium

and fungi. Transmissible diseases presently of greatest concern to the dental skilled are HIV, HBV, HCV and tubercle bacillus. A dental practitioner will become infected either directly or indirectly, i.e by a cut or wound, needle stick injury, aerosols of secretion, gingival fluid and natural organic dirt particles.The following are the important entry points of infection: cuticle of hands, oral epithelial tissue, nasal epithelial tissue, epithelial tissue of upper airways, bronchial tubes, alveoli and mucous membrane epithelium. so as to overcome from the infection that has been spread, an intensive information concerning the infection, mode of transmission and safety measures is important. throughout several dental procedures, the utilization of a rubber dam can eliminate nearly all contamination arising from secretions such as saliva or blood[2].

Prevention from contamination and cross-infection will be done by effective sterilization of instruments with the use of autoclave before and after use. Legnani et al. created an assessment of the aerosol contamination that arouse from dental procedures. Air contamination was measured by means of the Surface Air System technique and also the "plate" technique (Air microbial Index). it had been proven that in operating hours the common air microorganism load raised over 3 times, and also the air load levels were 1.5 times (aerobic bacteria) and 2 times (anaerobes) bigger as compared to the initial load[3].Hazardous waste includes X-ray fixers and film, chemical disinfectants, sharps like needles, blood-soaked dressings, mercury, silver, lead, numerous solvents and different chemicals. paper, plastic, latex and glass, a lot of of that is contaminated with body fluids, comprise a huge amount of dental waste[4,5]. a big increase in the amount of dental solid waste generated has been noted because of the increased use of plastic barriers, gloves and masks, believed to compromise regarding 90th of the solid waste[6]. This is often because of enhanced safety measures enforced further because the replacement of reusable things with disposable ones[5]. Other hazardous waste made in minor quantities includes fluorescent lamps, unused chemicals, medication and extremely inflammable cleaners for developer systems which will contain chromium, vapour steriliser chemicals and formaldehydes[7] . Mercury from amalgam is taken into account the foremost problematic waste because of its noxious potential[8] . Mercury will enter the surroundings as solid waste by the disposal of extracted teeth also as through the effluent collection system by the disposal of amalgam particles throughout dental operations[7,9].The Occupational Safety and Health Administration (OSHA) has revealed controlling occupational Exposure to

BloodbornePathogens in dental medicine. These osha guidelines are made to safeguard the worker, not the patient. The osha blood- borne infectious agent standard could be a comprehensive rule that sets forth specific necessities. Osha guidelines are made to stop the transmission of blood-borne diseases to workers. It includes needs for an exposure management set up, exposure management precautions, laundry procedures, necessary serum hepatitis vaccinations, housekeeping standards, and waste disposal rules. The Aim of this article is to review the biohazards of the materials used in dentistry and the proper methodology to dispose the waste.

Classification of Biohazardous Materials used in Dentistry[10]

Hazardous materials from dental offices may include:

1. Photo processing wastes - X-ray film , lead foils and shields , X-ray fixer , developer and cleaner .
2. Chemical sterilants wastes - also known as chemiclave solutions (or) disinfectants.
3. Line cleaner wastes
4. Universal wastes : batteries , fluorescent lamps , mercury thermometers , etc.
5. Amalgam capsules : (i) scrap (non-contact) amalgam . (ii) amalgam capsules (empty , leaking or unusable) (iii) contact amalgam (eg . Extracted teeth)
(iv) amalgam pieces captured by vacuum pump filters and screens.
6. Biomedical waste : blood-soaked dressings, used gloves , extracted teeth

Photo Processing Waste

Silver: A heavy metal which enters the body through disposal of dental waste. The radiographic waste contains silver. Less amount of waste is generated from dental offices and the concentration if silver in X-ray film ranges from 8g-12g/L [11].There is high level of silver in the X-ray films that are not developed and to avoid these it should be sent to proper X-ray disposal company , this can be avoided by using digital X-ray[12]

Lead : the X-ray packets contain lead, leachable ions and lead aprons. High doses of lead intake lead to reproductive toxicity, neurotoxicity, carcinogenicity, hypertension, renal function, immunology, toxicokinetics, etc[13]. Use of X-ray machines in dental offices

predispose dentists to suffer from ionizing radiation[14,15]. Lead aprons, periodic maintenance of the X-ray machine and radiation level sensors deal with radiation dangers[15,16]. The way to reduce the toxicity released by these methods and save people from the after effects caused by this is ,primarily to avoid the usage of such things. e.g. use of digital X-rays compared to the conventional film, developer/fixer combination[17].

Approximately over half the dental clinics have X-ray units. All of these clinics used one processing solution for the X-ray unit that was disposed of down the drain. However, no information on the composition or concentration of the used solution was provided on the packaging bottle[18]. As most dental clinics in several developing countries manufacture little amounts of waste separately, the silver recovery unit designed to fulfil the standards is required instead of the additional usually designed units that handle larger and continuous quantities of waste. Dentists ought to then follow the correct equipment during surgical procedure and maintenance procedures to make sure the quantity of silver remaining within the effluent is at proper levels. Moreover, lead foil, that are used to protect the X- ray film, ought to be treated as hazardous waste and not disposed of with the regular waste as is the current follow[19]. Lead aprons, used on patients throughout X-ray filming, contain lead that is hazardous. Therefore, lead aprons ought to be reused and came to the manufacturer once the helpful life is over.

Chemical Sterilants Waste

Workplace Hazardous Materials Information System (WHMIS) trains the staff those who need to work in such places . Dental waste has been demonstrated to contribute significantly to pollution of the environment if poorly treated[20] and that it can lead to cross-infection risks[21] such as deadly HIV and Hepatitis among others[22]. Chromium , cadmium etc are called heavy metals which are considered to be hazardous. Chromium causes respiratory damage , kidney failure while cadmium causes lung cancer , kidney damage[23]. Rubber dams , gloves , mask , headcaps are mandatory equipments for any dental procedure but the use of these materials releases few toxic gases like Chlorofluorocarbons , dioxin etc which causes neurological cancers, respiratory problems[24].Dental waste do not generally contain food remains to any large extent , but more of plastics (Polyvinyl Chloride PVC, Polyethylene, (PE), polypropylene (PPE). Any untreated waste should be properly labelled and handled by a waste hauler[25]. Contaminated sharps must be placed in a puncture-

resistant rigid container and treated prior to disposal.One should not pour sterilants into a septic system as this may significantly disrupt the bacteria which normally breakdownwastes[26,27].

Line Cleaners

Line cleaners generally contain alcohols and/or other hazardous materials. Products with such ingredients that go unused are considered hazardous waste and should be disposed properly.

• Disposal - It is done by City-sponsored Very Small Quantity Generated Program.

Universal Wastes

Needles, scalpels, glass carpules, burs, acid etch tips, files, blades and other similar objects , Their waste management includes collection in a red or yellow puncture resistant container with a lid that cannot be removed[27]. Aerosols cause airborne infections because they can stay airborne and has the potential to cause respiratory passage diseases. The various instruments that can cause airborne diseases ultrasonic scaler , air polisher , air driven hand pieces etc[28-30]. Autoclaving must be done to prevent contamination .Legnani.et.al made an assessment of the aerosol contamination resulting from dental Treatments. It was proved that during working hours the average air bacterial load increased over three times, and the air load levels were 1.5 times (aerobic bacteria) and 2 times (anaerobes) greater as compared to the initial load[31]. The practician who is using a disposable sharp item should be liable for its immediate safe management or disposal it is use. This should be at the point of use (i.e. the operatory or treatment room) unless transferred in an acceptable container. Used disposable needle syringe combinations, empty or partly used cartridges of anaesthetic agent solution, burs, needles, surgical knife blades, orthodontic bands, endodontic files and different single-use sharp things should be discarded in an approved clearly labeled , puncture and leak-proof containers.

Dental assistants ought to be trained to examine that sharps resembling burs and orthodontic wires are removed by the operator before commencing the transformation procedure.Burs ought to be faraway from hand-pieces before removing the hand-piece from the dental unit, to cut back the danger of sharps injury.Disposable sharps, if not placed by the operator into a sharps bin placed at the chairside, may instead be placed when use during a specific puncture-

proof dish to minimizerisk.Sharps containers should be placed in a very safe position inside the clinic to avoid accidental tipping over and should be out of the reach of young children.

Amalgam Wastes

Two main kinds of dental restoration practices are used: dental composite (otherwise referred to as white fillings), a mixture of glass or ceramic particles spread during a photo-polymerizable synthetic organic resin matrix, and amalgam, consisting of roughly 1:1 mixture of metallic mercury and a pulverized alloy consisting of silver, tin, copper, zinc additionally to different metals . it's thus because of the high concentration of mercury that this latter waste is assessed as hazardous. However, the utilization of elemental mercury in amalgam rather than the safer encapsulated amalgam is usually most preferred because it is less costly, even though accidental spills will put the dental personnel in danger of mercury toxicity.Mercury is neurotoxic , nephrotoxic and bio accumulative element and one of the main source of it in dentistry is amalgam. It can get into the environment through waste water, scrap amalgam or vapors. Vaporous mercury waste management includes: (i) storing unused elemental mercury in a tightly sealed container, (ii) contacting a certified biomedical waste carrier (CWC) for recycling or disposal, (iii) using a “mercury spill kit” in case of a spill of mercury, (iv) reacting unused elemental mercury with silver alloy to form scrap amalgam, (v) not placing elemental mercury in the garbage, and (vi) not washing elemental mercury down the drain. Humans are continuously exposed to mercury via food, air, water[32].During the placement and removal of dental amalgam restorations, a variety of waste products is generated:(i)elemental mercury vapour–released from dental amalgam alloy,(ii)dental amalgam scrap–the amalgam particles that have not come into contact with the patient,(iii)amalgam waste–the particles that have come into contact with patient secretions,(iv)amalgam sludge–the fine particles present in dental office wastewater, commonly trapped in chair-side traps and vacuum filters[3,33].Although amalgam separators in the certification process are required to remove at least 95% of incoming mercury in a standardized laboratory test, their efficiency in practical use has not been properly investigated mercurypoisoning[34] can be characterized by tumours of the face, arms or legs and may be associated with progressive, tremulous illegible handwriting with slurred speech[35]. The amalgam waste ought to stay in a very properly labeled sealed container that's appropriate for storing contaminated amalgam waste and will be sent for the contents to

be recycled, chiefly mercury and silver. Used and empty amalgam capsules is also disposed of as solid waste since they're non-hazardous.

Blood-Soaked Dressings

All biomedical wastes should be color coded and marked with the workplace hazardous Material information system (WHMIS) biohazard image. medicine wastes will solely be transported by a corporation with correct certification. biomedical wastes are occupational health and safety concerns for those who come in close contact with them[36]. Non-dripping gauze and extracted teeth don't seem to be thought of biomedical; but teeth with amalgam restorations can not be placed within the incinerator for disposal.cotton and extracted teeth, within the trash with the regular waste. Swabs or dressings that are contaminated with blood or different body fluids are regulated by infectious waste rules . These ought to be placed in sealed, durable impermeable bags to stop escape of the contained things.Human anatomic waste includes all the body parts, biopsy undergone tissues and also extracted teeth. All thesemust be disposed in yellow bags or containers[37].

Standard Precautions to be Followed by a Dental Practitioner

There are several ways of precautions to be administered by the dentist . Amongst them the two basic precautions to be followed are the following -

1. Hand hygiene
2. Personal protective equipment

Hand Hygiene

Hand hygiene may be a general term applying to processes reaching to cut back the quantity of microorganismsonhands. This includes either the applying of a dry antimicrobial agent, e.g. alcohol-based hand rub (ABHR), to the surface of the hands, or the employment of soap/solution (plain or antimicrobial) and water, followed by patting dry with single-use towels.The HHA protocol is to use an ABHR for all clinical situations wherever hands are visibly clean. The traditional routine in practice ought to be for dental employees to use ABHR between patient appointments and through interruptions with intervals the one appointment. ABHR is applied onto dry hands and rubbed on for 15-20 seconds, after which period the hands are dry.

Hand hygiene is needed once removal of gloves. This should be done before the dentist writes or types up patient notes. Practitioners shouldn't shake a patient's hand once greeting them when they are in the reception while not having first completed hand hygiene.ABHR usually will be used as often as is needed. However,a compatible moisturiser ought to be applied up to four times per day. ABHR should solely be used on dry skin;wet hands dilutes the product therefore decreasing its effectiveness.

Personal Protective Equipment

There are a list of personal protective equipments to be used by the dentist-

1. Gloves
2. Mask
3. Eye protection
4. Protective clothing
5. Footwear

Gloves

Dental practitioners and clinical support employees should wear gloves whenever there's risk of exposure to blood, saliva or different body secretions or when hands can come in contact with secretion membranes. This implies gloves should be worn for all clinical procedures. Wearing gloves doesn't replace the necessity for hand hygiene because hands might still become contaminated because of producing defects in new gloves that weren't obvious to the user, or due to injury (such as tears and pinpricks) that occur to the gloves throughout use.Dental materials that are madeof components of methacrylate and its polymer are found to be important reason for contact dermatitis, aggravation of skin conditions, eyes or mucous membranes, allergic dermatitis, asthma and paresthesia in the fingers[38].Disposable gloves employed in patient care should not be washed before or once use nor ought to they be reused. A brand new pair of gloves should be used for every patient and altered as soon as they're cut, torn or perforated.

Masks

Dental procedures will generate huge quantities of aerosols of 3 microns or less in size and variety of diseases could also be transmitted via the airborne (inhalational) route. In the

dental surgery surroundings, the foremost common causes of airborne aerosols are the high-speed air rotor handpiece, the supersonic scaler and also the three-way syringe. The aerosols created could also be contaminated with microorganism and fungi from the oral cavity (from saliva and dental bio films),as well as viruses from the patient's blood[30].Therefore, dental practitioners and clinical support employees should wear appropriate fluid-resistant surgical masks that block particles of 3 microns or less in size. However, it's recommended that masks be worn during all the times while treating patients to stop contamination of the operating area with the operator's respiratory or nasal secretions/organisms.

Eye Protection- Dental practitioners and clinical support employees should wear protective eyewear to safeguard the mucous membranes of the eyes throughout procedures wherever there's the potential for penetrating trauma or exposure to aerosols, splattering or spraying with blood, saliva or body substances.Eyewear protects the eye from a broad variety of hazards as well as projectiles and may be worn for many clinical procedures[27].Protection from projectiles is especially necessary during scaling, while using rotary instruments (particularly when removing existing restorations), cutting wires and cleansing instruments and equipment.

Protective Clothing

Protective clothing (e.g. disposable gown), ought to be worn when treating patients while it's possible aerosols or splatter are likely to be generated or once contaminated with blood or saliva. the foremost appropriate style of protective clothing and equipment used varies according to the nature of the procedure and may be a matter of skilled judgement. Wherever there's a risk of enormous splashes with blood or body substances, imperviable protective clothing should be worn[33]. The protective gown worn within the clinical space should be removed before consumption of food, drinking, taking a break or leaving the clinical premises.

Footwear- Dentists and clinical support employees like the assistant ,receptionistand the other staffs should wear closed footwear which will help them protect from injury or contact with sharp items such as the accidentally dropped sharps or spilt chemicals[32].

Conclusion

Sufficient knowledge and adequate information regarding occupational hazards and its prevention will contribute in providing quality care to patients without any doubt. The global literature focuses strictly on control of infections and appropriate management of potentially infected materials, owing to the high profile of dentistry regarding infection transmission. The dentist should follow the proper precautions that will protect them and their patients from getting affected through the hazardous waste obtained from the clinic.

Biological Properties of Turmeric

Priyadharshni S[1], Anitha[2], E. Roja[3]
Graduate Student[1], Reader[2], Department of Biochemistry,Tutor[3], Department of Public Health Dentistry,
Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Turmeric is traditionally used as a spice that comes from the root curcuma long, a member of the ginger family. The main ingredient in turmeric is curcumin. The characteristic yellow colour of turmeric is due to curcumin. Turmeric forms a part of most Indian curry powder. A wide range of biological activities like anticancer, antimicrobial, antiinflammatory, anticarcinogenic, antimutagenic, antifertility, antiprotozoal, antidiabetic and free radical scavenging activity of the plant suggests a logical basis for its traditional use in foodstuff. Turmeric powder is used to treat a wide variety of diseases. In Unani medicine, turmeric has been used for conditions such as liver obstruction and jaundice and has been applied externally for ulcers and inflammation. Safety evaluation indicates that both turmeric and curcumin are well tolerated at a very high dose without any toxic effects. Thus, both turmeric and curcumin have the potential for the development of modern medicine for the treatment of various diseases. Turmeric is highly estimated by the Indians and has religious importance because of its yellow colour resembling sunlight.

Keywords:*Biological activities, disease, curcumin, healing, powder*

Introduction

Turmeric is a medicinal plant extensively used in Ayurveda, unani and Sidda medicine as home remedy for various diseases.Turmeric is one of the nature's powerful healers It is also considered as auspicious and is a part of religious rituals[1]. Turmeric has been used for 4000 years to treat a variety of ailments. Turmeric is used as a food preservative, food additive and colouring agent[2]. Since its initial medical use in Ayurveda to bring "heat"to the body'shot/cold balance, many health conditions have been treated by turmeric.Its main bioactive compound, curcumin, is thought to be responsible for the many anti-inflammatory and antioxidant properties which benefit conditions as broad as healing wounds, cholesterol, and triglyceride reduction, reduction of sclerosing of bile ducts in the liver in cirrhosis and improving man digestive conditions such as colic[3]. Curcumin in turmeric has been shown to stimulate the production of bile by the gall bladder. Curcumin is also a powerful antioxidant;antioxidant scavenge damaging particles in the body known as free radicals, which damage cell membrane tamper with DNA and even cause cell death. The colour of turmeric is due to curcumin. As Indian culture worshipped solar system turmeric is specially protected as it contains sun coloured yellow dye. Turmeric has 46 synonyms but it is best known as Haridra in Sanskrit and Pita: yellow, Gauri:brillant, Rajini:night in Hindi. It belongs to group of aromatic spices and when added to various food preparations preserved their freshness and nutritive value. Curcumin is the principalcurcumoid found in turmeric[4]. Turmeric held a place of honour in Indian traditional Ayurveda medicine. In Ayurveda, it was prescribed for the treatment of many medical problems ranging from constipation to skin diseases. It was used as digestive aid and treatment for fever, inflammation, wounds, infections, dysentry, arthritis, injuries, trauma, jaundice, and other liver problems. In unani turmeric is considered to be safest herb of choice for blood disorders since it purifies, stimulates and builds blood. Turmeric is relatively broad spectrum anti-fungal. Turmeric exhibits antioxidant activity and protect from free radical damage. Curcuma also exhibits anti tumor activities and prevent cancer. It inhibits topoisomerase enzyme, which is required for cancer[5]. Turmeric and its constituents have the potential for the development of modern medicine of the treatment of various diseases[6].

Plant Morphology

The turmeric (curcuma longa) plant, a perennial herb belonging to the ginger family, is cultivated extensively in south and southeast tropical as Saveetha University[7].Turmeric was described as c.longa by linnaeus and its taxonomic position is as follows:

Class -Liliopsida
Subclass -Commelinids
Order - Zingiberales
Family - Zingiberaceae
Genus - Curcuma
Species- Curcuma longa

The wild turmeric is called C.aromatica and the domestic species is called C. Longa[8].

India is the largest producer of turmeric in the world (93.7% of the total world production) and is cultivated in 150,000hectares in India. Maximum area under turmeric is in AndhraPradesh, followed by Maharashtra, Tamil Nadu, Orissa, Karnatakaand Kerala. It is found throughout the south and south east Asia with a few species extending to China, Australia and the South Pacific[8]. The rhizome is a yellowish-brown with a dull orange interior that looks bright yellow when powdered. Rhizome measures 2.5-7.0 cm (in length), and 2.5 cm (in diameter) with small tuber branching off [9].

Antioxidant Property

The antioxidant activity of curcumin was reported as early as 1975. It acts as a scavenger of oxygen free radicals. It can protect haemoglobin from oxidation.In vitro, curcumin can significantly inhibit the generation of reactive oxygen species (ROS) like superoxide anions, nitrite radical generation by activated macrophages[10]. Curcumin prevents oxidative damage during indomethacin induced gastric lesion not only by blocking inactivation of gastric peroxidase, but also by direct scavenging of hydrogen peroxide and OH (unpublished observation). Since ROS have been implicated in the development of various pathological conditions[11],curcumin has the potential to control these diseases through its potent antioxidant activity. Curcumin exerts powerful inhibitory effect against hydrogen peroxide-induced damage in human keratinocytesand fibroblasts[12]. Contradictory to the above-mentioned antioxidant effect, curcumin has pro oxidantactivity. Kelly reported that curcumin not only failed to prevent single strand DNA breaks by hydrogen peroxide, but also caused

DNA damage. As this damage was prevented by antioxidant alpha-tocopherol, the pro oxidant role of curcumin has been proved(13). Reactive oxygen species (ROS) are associated with many biological phenomena such as inflammation, carcinogenesis and aging (Amin, 2012). Todd (1985), has reported the antioxidant effect of hexane and methanol extracts of rhizome at a concentration of 0.1%. They found that hexane extract of dried rhizome at a concentration of 0.06% was inactive when tested on lard however, the methanol extract was active (Lee et al., 1982). According to a study by Shalinin et al. (1987), hot water extract of a commercial sample of tuber was active vs. protection of DNA against per oxidative injury. Water extract of rhizome was active on rat brain vs. Fe2+/ ascorbate Fe2+/ TBH induced lipid per oxidation. The biological activity was highly dose dependent, IC50 (median inhibitory concentration) 100 mcg/ml. The extract was also active vs. lipid per oxidation induced by TBARS, IC50 50 mcg/ml which means that the activity depends on the doses and varies with dose variation (Selvam, 1995).

Anti-Inflammatory

Curcumin is effective against carrageenin-induced oedema in rats and mice(14). The natural analogues of curcumin, viz. FHM and BHM, are also potential inflammatory agents[15]. The volatile oil and also the petroleum ether, alcohol and water extracts of C.longa show inflammatory effects[16]. The anti rheumatic activity of curcumin has also been established in patients who showed significant improvement of symptoms afteradministration of curcumin[17]. That curcumin stimulates stress-induced expression of stress proteins and may act in a way similar oxylated phenols and an enol form of beta-diketone;the structure shows typical radical-trapping ability as a chain-breaking antioxidant[18]. A cohort study of 32 patients found that curcumin was as effective as corticosteroids for chronic anterior uveitis (as demonstrated by improved vision, decreased keratic precipitates, and a break of synchiaeassessedby slit lamp examination)[19].Another small cohort study cumin reduced or resolved inflammatory orbital pseudotumor (as evidenced by reduced ocular swelling, normal ocular movements, and absence of diplopia) [20].

There is a great number of papers in the literature relating the activity of compounds extracted from C. longa L. being potent inhibitors of inflammation. These substances can be classified as curcuminoids, analogues of diarylheptanoids. There are two models of inflammation to be studied: chronic models (cot- ton pellet and granuloma pouch), where the inflammation and granulomas develop during a period of time (several days), indicating the proliferative phase of inflammation; and acute models, where acute effects of anti-

inflammatory agents can be studied, testing their inhibitory action on the development of rat paw edema.

Mukophadhyay (1982) demonstrated the activity of curcumin and other semi-synthetic analogues (sodium curcuminate, diacetylcurcumin, triethylcurcumin and tetrahydrocurcumin) in carrageenin-induced rat paw edema and cotton pellet granuloma models of inflammation in rats. In these experiments the authors used ferulic acid and phenylbutazone (reference drug). Curcumin and its analogues showed similar action in carrageenin- induced paw edema in rats; however the sodium curcuminate was the most potent analogue and was more water-soluble than curcumin. Among the curcumin analogues, triethylcurcumin was the most potent anti-inflammatory in the chronic model of inflammation, when compared with the others and with the drug reference; and tetrahydrocurcumin showed no activity. In the acute inflammation condition, all the substances were more effective. The authors concluded that the activity of the compounds used in these experiments, would depend on the model of inflammation. Arora (1971) investigated the anti-inflammatory activity in different fractions of the petroleum ether extract of the rhizomes of turmeric (two constituents) in animals. They found that the extracts reduced the granuloma growth and no toxic effects were observed. Chandra and Gupta (1972) demonstrated the anti-inflammatory and anti-arthritic actions of volatile oil of C. longa L. Ghatak and Basu (1972) showed the action of sodium curcuminate as an anti-inflammatory agent, being better than curcumin and hydrocortisone acetate, in experimental inflammation induced by carrageenin and formalin in albino rats (ED50 = 144μg/kg), its more soluble in water than curcumin and no side effects were observed.

Pharmacological actions of curcumin as an anti- inflammatory agent have been examined by Srimal and Dhawan (1973). In this work, the authors re- ported that the compound was effective in acute as well as chronic models of inflammation. The potency of this drug is approximately equal to phenylbutazone in the carrageenin-induced edema test, but it is only half as active in the chronic experiments. It was observed that curcumin was less toxic than the reference drug (no mortality up to a dose of 2 g kg-1). Huang (1992) examined the inhibitory effects of curcumin on the proliferation of blood mononuclear cells and vascular smooth muscle cells. In blood mononuclear cells, curcumin was capable to impair the response of cells to mitogen, PHA and the response to alloantigen, MLR. The investigators suggested that curcumin could be use clinically in transplant atherosclerosis. The cinnamicacid derivatives were less active than curcumin. Ammon (1992) demonstrated curcumin as an inhibitor of leucotriene formation in rat peritoneal polymorph nuclear

neutrophils (PMNL), with an EC50 of 27 x 10-7 M, in contrast, the hydrocortisone did not show any effect.

Curcumin enhances wound healing Tissue repair and wound healing are complex processes. Curcumin has very effective wound healing activity, examined in rats and guinea pigs. In situ hybridisation and PCR analysis shows an increase in the mRNA transcripts of transforming growth factor beta 1 (TGFβ1) and fibronectin in Curcumin treated wounds. Transforming growth factor beta 1 enhance wound healing, therefore it is possible that Curcumin modulates TGF β1 activity.

Anti-Fertility

Petroleum ether and aqueous extracts of turmeric rhizomes show 100% anti-fertilityeffect in rats when fed orally[21]. Implantation is completely inhibited by these extracts. Curcumin inhibits 5a-reductase, which converts testosterone to 5adihydrotestosterone, thereby inhibiting the growth of flank organs in hamster[22]. Curcumin also inhibits humansperm motility and has the potential for the development of a novel intravaginalcontraceptive[23]. Turmeric regulates menses, decreases intensity and pain of periods, decreases amenorrhea and decreases uterine tumours. Turmeric is a mild and supportive uterine stimulant.

Anti-Cancer

Curcumin acts as a potent anti-carcinogeniccompound.Among various mechanisms, induction of apoptosis plays an important role in its anti-carcinogenic effect.It induces apoptosis and inhibits cell-cycle progression, both of which are instrumental in preventing cancerous cell growth in rat aortic smooth muscle cells[24]. The mechanism responsible for apoptosis involves inhibition of cell signalling pathway genes like DNA damage(25). Turmeric inhibits the topoimerase enzyme, which is required for the replication of cancer and parasite cells. It strongly inhibits DNA and RNA synthesis and increases mitochondrial membrane permeability ; a very significant property in the apoptosis of proliferating cells. It can also prevent proliferation by cell cycle arrest in the G2/M phase in a variety of malignant tumours [26]. G2/M arrest renders cells more susceptible to the cytotoxic effects of radiation, suggesting that curcumin may find significance as a radio sensitizer[27].The ability to inhibit COX-2 gene over-expression which is implicated in the carcinogenesis of many different tumours, has suggested a plausible role of curcumin to protect children against leukaemia. Curcumin was shown to induce apoptosis among

leukaemia B lymphoma cells and inhibits the multiplication of leukaemia cells in laboratory studies[28]. Curcumin also suppresses human breast carcinoma through various pathways.

Anti-Microbial

Turmeric extract and the essential oil of Curcuma longa inhibit the growth of a variety oil of bacteria , parasites, and the pathogenic fungi. The aqueous extract of turmeric rhizomes hasanti-microbial effects [29]. Both curcumin and the oil fraction suppress growth of several bacteria like streptococcus, staphylococcus, lactobacillus, etc[30].Ether and chloroform extracts and oil of C.longa have anti-fungaleffects. Crude ethanol extract also possess anti-fungalactivity. Turmeric oil is also active against Aspergillusflavus, A.parasiticus, Fusariummomiliforme. The ethanol extract of the rhizomes has anti-Entamoebahistolytica activity. Curcumin has anti-Leishmania activity in vitro[31].Several synthetic derivatives of curcumin have anti-L.amazonensis effect. Anti-plasmodium falciparum and anti-L.major effects of curcumin have also been reported. Turmeric has shown to have anti -viral activity[32].It acts as an efficient inhibitor. Curcumin prevents galactose-induced cataract formation at very low doses. Both turmeric and curcumin decreases blood sugar level in alloxan-induced diabetes in rat.Curcumin also decreases advanced glycaton end products inducedcomplications in diabetes mellitus [33].

Anti-Viral Activity

Cai (1988), showed in a study that hot water extract of dried rhizome in cell culture was active on vesicular stomatitis virus. The prescription included 10g each of Curcuma longa rhizome, Rheum officinale root, Cimicifugafoetida rhizome, Anemarrhenaasaphodeloides rhizome, Areca catechu seed, Magnolia officinalis bark and Scutellariabaicalensis root along with 5g Amomumtsaoko fruit, together with insects Bombyxmori and Cryptotympanapustulata. May et al. (1978), reported that water extract of dried rhizome in cell culture at a concentration of 10% was inactive on Herpes Virus Type- 2, Influenza virus A2 (Manheim 57), Polio-II and Vaccinia virus.

Anti-Microbiological Activity

Chang (1989), carried out a study to evaluate the antimutagenic effect of hot water extract of dried rhizome in comparison with Aflatoxin B1 induced mutagenesis and Aflatoxin and Mitomycin induced mutagenesis. Chang and co-workers (1989), found that hot water extract of dried rhizome on agar plate at concentration of 40 mg/plate and at a minimum toxic dose were inactive on Salmonella typhimurium TA100 vs Aflatoxin B1 induced mutagenesis. Metabolic activation had no effect on the results. Dried rhizome extract on agar plate at a concentration of 50 mg/ml was inactive on Salmonella typhimurium TA1535 vs Aflatoxin and Mitomycin induced mutagenesis. Another study by Deshpande.(1995) shows that water extract of rhizome at a concentration of 0.33 mg/ml was active on rat liver microsomes and the formation of labeledbenzo[a]pyrene-DNA adducts was inhibited. Infusion at a concentration of 2 mcg/ plate on agar plate was active on Salmonella typhimurium TA100. 1-methyl-3 nitro-1- nitroguanidine-induced mutagenesis was inhibited by 25%. There was a 38% inhibition of 4-nitro-Dphenylenediamineinduced mutagenesis of S. typhimurium TA98. Infusion of rhizome administered intra-gastric to mice at a dose of 3mg/animal was active. The incidence of benzo[a]pyrene induced bone marrow micro nucleated cells was decreased 40% by pre-treatment with the extract (Azuine, 1992). Powdered rhizome at a concentration of 0.033 mg/ml was active on rat liver microsomes. Formation of labeledbenzo[a]pyrene-DNA adducts was inhibited (Deshpande et al., 1995). Powdered rhizome administered intra-gastric to rats at a dose of 0.5% of the diet was active. Animals fed the diet for one month before being given 3-methylcholanthrene intraperitoneally, produced urine with reduced mutagenicity on S. typhimurium strains TA100 and TA98, with or without activation with S9, as assessed by Ames test (Polasa., 1991).

Toxicological Properties

Curcumin is considered to have a low toxicity in man and animals. In a clinical trial with 25 volunteers, administration of up to 8 gm of Curcumin per day has no apparent toxic sign. In another clinical trial in which humans were given 1.25-2.5 gm Curcumin per day confirmed the apparent safety of the substance (Chainani-Wu, 2003). There are no reports of adverse effects of either Curcumin or its analogues except for rare cases of contact dermatitis. Many women in Asia apply turmeric to their skin in an effort to minimize unwanted hair growth, but few experience dermatitis. Oral administration of Curcumin to rats at doses up to 5 g/kg caused no overt signs of toxicity. The American Herbal Association classifies turmeric as a

menstrual stimulant and some sources recommended avoiding Curcumin in pregnancy. Its use is not recommended during breast-feeding, as effects on breast-feeding infants are unknown (Oetari, 1996). Turmeric may have an antiplatelet activity (Shah, 1999), and its concurrent use with anticoagulants may lead to an additive effect. Although there are no reports of this in humans, its use should be avoided in patients with bleeding disorders and bile duct obstruction and should only be used under the supervision of a physician in patients with gallstone[34].

Adjuvants

Piperine is known to inhibit hepatic and intestinal glucuronidation. When combined with piperine, the elimination half-life and clearance of curcumin were significantly decreased, resulting in an increase of bioavailability to 154% that of curcumin alone in rats. In contrast, the increase in bioavailability was 2000% in humans, clearly showing that the effect of piperine on bioavailability of curcumin is much greater in humans than in rats. A human volunteer trial conducted by our group revealed the enhancing effect of piperine on serum curcumin level. Six healthy adult male human volunteers took 2 g of curcumin with or without 5 mg piperine (as Bioperine1) in this cross-over design study. Three subjects were randomized to receive curcumin only, while the remaining three received the curcumin + piperine combination. One week following initial drug administration, volunteers were crossed over to the other therapy and blood samples were obtained for evaluation. The presence of piperine was found to double the absorption of curcumin.

The effect of piperine on tissue uptake of a radiolabeled fluoropropyl-substituted curcumin was evaluated in mice. Mice that received piperine had 48% greater brain uptake of curcumin after 2 min than mice that did not receive piperine. However, the uptake in other organs was not found to be significantly improved by piperine in this study; the authors think this observation can be explained by the poor solubility of piperine in 10% ethanolic saline (injection medium).

Some other agents that showed a synergistic effect when used in combination with curcumin in various in vitro studies look promising for further evaluation. Five patients with familial adenomatous polyposis who had undergone colectomy received curcumin 480 mg and quercetin 20 mg orally 3 times a day. The number and size of polyps were assessed at baseline and after therapy. All five patients had decreases in polyp number and size, 60.4% and 50.9%, respectively, from baseline after a mean of 6 months of this treatment. Though

the authors did not compare the effects of this combination treatment with those of the single agents, this study at least throws light on the therapeutic value of this combination[35].

The synergistic inhibitory effect of curcumin and genistein against pesticide-induced growth of estrogen-dependent MCF-7 breast carcinoma cells has been reported. It was showed that a combination of curcumin and genistein completely inhibited the cellular proliferation induced by an individual pesticide or a mixture of pesticides, and that the inhibitory effect was superior to the individual effects of either curcumin or genistein. Curcumin uptake within rat skin after topical application of a curcumin hydrogel, with or without eugenol or terpineol pretreatment, was evaluated in an in vivo study. The effects of eugenol and terpeneol as enhancers of skin curcumin absorption were demonstrated; 8h after application, curcumin levels in skin were 2.2- and 2.5-fold greater, respectively, in mice that received eugenol or terpeniolpretreatment than in mice that received curcumin alone. These observations indicate that these absorption- enhancing agents may also be effective as adjuvants. Epigallo-catechin-3-gallate, a component of green tea, could counteract certain activities attributed to curcumin. BCM-95 (also called Biocurcumax) curcuminoids combined with turmeric oil (turmerons) in a specific proportion enhanced the bioavailability and showed better absorption into blood and had longer retention time than curcumin alone. Currently a multicenter, phase II, randomized, double-blinded, placebo-controlled clinical study is ongoing to assess the efficacy and safety of BCM-95 in oral premalignant lesions or cervical cancer.

Conclusion

Now-a-days, economic and medicinal importance of turmeric (Curcuma longa Linn.) is an established fact, besides further research methodology is practiced to reach the extreme and extensive value of its diverse pharmacological and other uses. It has been appreciably used in traditional medicine as a household remedy for various diseases. Its anti-inflammatory, anticancer and anti-oxidant properties if exploited efficiently may benefit the mankind in colorful ways. It has a low toxic effect on body hence large doses can be given without any fear of toxicity that reflects its broad therapeutic index. This plant has benefited us of its various medicinal values besides other utilities.Turmeric has been used in Ayurveda medicine since ancient times, with various biological applications. Although some work has been done on the positive medical applications, no studies for drug-development have been carried out as yet. Although the crude extract has numerous medical applications,

clinical applications can be made only after extensive research on its bioactivity, mechanism of action, pharmacotherapeutics and toxicity studies. However, as curcumin is now available in pure form, which a shows a wide spectrum of biological activities, it would be easier to develop new drugs from this compound after extensive studies on its mechanism of action and pharmacological effects. Recent years have seen an increased enthusiasm in treating various diseases withnatural products. Curcumin is a non-toxic, highly promising anti-oxidant compound having a wide spectrum of biological functions. It is expected that curcumin may find application as a novel drug in the near future to control various diseases, including inflammatory disorders, carcinogenesis and oxidative stress-induced pathogenesis. Thus, Turmeric holds promises of holding significant clinical benefits.

Abstract

Proper handling and disposal of medicine wastes plays a vital parts of health care work place infection management program. Effective waste disposal isachieved solely by considering the assorted parts of the waste management system as an integral a part of hospital designing and planning. Medical care is important for our life and health, however the waste generated from medical activities represents a true drawback of living nature and human world. Improper management of waste generated in health care facilities causes an instantaneous health impact on the community, the health care employees and on the atmosphere. Indiscriminate disposal of biomedical waste management and exposure to such waste possess serious threat tothe atmosphere and to human health that needs specific treatment and management before its final disposal. Most of the foundations world-wide don't seem to be specific for dental biomedical waste management and hinder simple understanding by dental practitioners.Considering its disposal and ill-effects on health and the atmosphere, a method of dental waste segregation protocol was needed. The current review deals with the definition, source, classification, methods to dispose and problems related to handling and disposal of bio medical waste.

Key Words: *Biomedical, waste, management, disposal, practice*

Introduction

Biomedical waste management has emerged as a problem of major concern not only to hospitals, institution authorities but also to the surroundings. The biomedical wastes generated from health care units depends on a variety of things like waste management strategies, forms of health care units, occupancy of tending units, specialization of tending units, quantitative relation of reusable things in use, handiness of infrastructure and resources etc [1]. Health care facilities like laboratories, clinics, nursing homes, medical, dental,and veterinary hospitals, generate a waste stream varied in its composition.Among these facilities the hospitals contribute most wastes [2].The proper management of biomedical waste has become a worldwide humanitarian topic today. Hazards of poor biomedical waste management have aroused as a major concern in affecting human and the environment [3]. Hospital waste could be a potential jeopardy to the health care staff, public and flora and fauna of the realm [4].According to Biomedical Waste (Management and Handling) Rules, 1998 of India “Any waste which is generated during the diagnosis, treatment or immunization of human beings or animals or in research activities pertaining thereto or in the production or testing of biological".Inadequate and inappropriate handling of health-care waste could have serious public health consequences and a major impact on the environment. Considering the increasing range of dentists in urban areas and magnified awareness regarding the dental treatment amongst the general public, it is more important to create awareness on biomedical waste management and make it anintegral feature of dental services.The current review deals with the definition, source, classification, methods to dispose and problems related to handling and disposal of bio medical waste management

Need for Biomedical Waste Management

The content of infectious waste within the total waste generated in an hospital may be 20 percentage. However it haspotential to infect whole of hospital waste if it is not transported in and prescribed manner [4]. Waste generated at hospitals and health care facilities is totally different from, general municipal waste. The municipal waste may require only one system for assortment, transportation and final disposal. Against this the biomedical waste may have additional systems, since it includes body components, human

and animal tissues, radioactive material, gauze, cotton, plastics, plaster-of-paris casts, infected liquid waste, blood and laboratory wastes. Medical waste generated at totally different health care facilities presents environmental and public health risks. Inappropriate treatment and disposal will unfold infectious diseases like TB, hepatitis, typhoid, HIV infection, or perhaps AIDS [2,5]. Injuries from sharps leading to infection among all categories of hospital personnel and waste handler. Risk of infection outside hospital for waste handlers, scavengers and at time general public living in the hospitals vicinity is always high.

Classification of Biomedical Waste

The World Health Organization (WHO) has classified biomedical waste into eight categories:

1. General Waste
2. Pathological
3. Radioactive - It is genotoxicand thus may affect genetic material. The effects of exposure can range from headache, dizziness, and vomiting to malignancies.
4. Chemical wastes
5. Pharmaceuticals - Hazards from chemical and pharmaceutical waste [5]. Many of the chemicals are toxic, genotoxic, corrosive, flammable, reactive, explosive or shock sensitive. Although present in small quantity they may cause intoxication, either by acute or chronic exposure and injuries, including burns. Reactive chemicals may form highly toxic secondary compounds
6. Sharps -Pathogens in infectious waste may enter the human body through a prick, abrasion or cut in the skin, through mucous membranes by inhalation or by ingestion. There is a particular concern about infection with Human immunodeficiency virus and hepatitis virus B and C, for which there is a strong evidence of transmission via health-care waste. [5].
7. Infectious to potentially infectious waste
8. Pressurized containers

Sources of Biomedical Waste

The sources of health-care waste are classified as major or minor according to the quantities created. [1-5]

Major Sources

- Govt. hospitals/private hospitals/nursing homes/ dispensaries.
- Primary health centers.
- Medical colleges and research centers/ paramedic services.
- Veterinary colleges and animal research centers.
- Blood banks/mortuaries/autopsy centers.
- Biotechnology institutions.
- Production units.

Minor Sources

- Physicians/ dentists' clinics
- Animal houses/slaughter houses.
- Blood donation camps.
- Vaccination centers.
- Acupuncturists/psychiatric clinics/cosmetic piercing.
- Funeral services.
- Institutions for disabled persons

Table 1: Steps in management of health care wastes

Color cryptography	**Type of Material**	**Waste Category**	**Treatment option**
Yellow cover	Plastic bag	Human Anatomical Waste, Animal Waste. Human tissues, organs, body parts including the waste generated from animals used in experiments or testing in veterinary hospitals or colleges or	Incineration or burning

		animal houses and fetus below the viability period. **Expired or Discarded Medicines** **Chemical Waste:** Chemicals used in production of biological and used or discarded disinfectants. Discarded linen, mattresses, beddings contaminated with blood or body fluid. **Chemical Liquid Waste :** Liquid waste generated due to use of chemicals in hospitals and health care centers.	
Red cover	Plastic bag	Infected /Non-Infected Plastics Contaminated Wastes generated from disposable items such as tubing, bottles, intravenous tubes and sets, catheters, urine bags, syringes (without needles and fixed needle syringes) and vaccutainers with their needles cut) and gloves	Shredding after Autoclaving
Blue cover	Plastic bag	Broken or discarded and contaminated glass including medicine vials and ampoules except contaminated cytotoxic wastes.	Autoclaving /Destruction
Black cover	Carboy bag	Needles, syringes with fixed needles, needles from needle tip cutter or burner, scalpels, blades, or any other contaminated sharp object that may cause puncture and cuts. This includes both used, discarded and contaminated metal sharps	Autoclaving /Destruction

Problems Associated with Biomedical Waste

A major issue related to current Bio-Medical waste management in many hospitals is that the implementation of Bio-Waste regulation is unsatisfactory as some hospitals are disposing of waste in a haphazard, improper and indiscriminate manner. Various communicable diseases spread through water, sweat, blood, body fluids and contaminated organs and it is very important to be disposed properly [4-6]. The bio medical waste scattered in and around the hospitals invites flies, insects, rodents and dogs that are responsible for the spread of communicable disease like plague and rabies. Improper disposal of disposable syringes, needles, IV infusion sets and other articles like glass bottles without proper sterilization are responsible for the transmission of diseases. It became the primary responsibility of Health administrators to manage hospital waste in the safest and eco-friendly manner[6].The waste, if allowed to accumulate, is a health hazard, because it decomposes and favors fly breeding, it attracts rodents and vermin, the pathogens, which may be present in the waste may be conveyed back to man's food through flies and dust. There is a possibility of water and soil pollution. Heaps of refuse present an unsightly appearance and nuisance from bad odors [7].

Biomedical Waste Management Process

There is a big network of Health Care Institutions in India. The hospital waste like body parts, organs, tissues, blood and body fluids along with soiled linen, cotton, bandage and plaster casts from infected and contaminated areas should be properly disposed [8]. This involves the following steps,

1. Waste collection
2. Segregation
3. Transportation and storage
4. Treatment & Disposal
5. Transport to final disposal site
6. Final disposal

Treatment and Disposal Methods

Incineration Technology

It is a high temperature thermal process involving combustion of the waste under controlled condition for converting them into inert material and gases. Incinerators can be oil fired or electrically powered or a combination of both. Three types of incinerators are used for hospital waste - multiple hearth type, rotary kiln and controlled air types. All the types can have primary and secondary combustion chambers to ensure optimal combustion.It is a controlled combustion processin which the waste is completely oxidized and harmful microorganisms present in it are destroyed/ denatured under high temperature[7-9]

Non-IncinerationTechnology

Non-incineration treatment includes four basic processes: thermal, chemical, irradiative, and biological. The main purpose of the treatment technology is to decontaminate waste by destroying pathogens [10-12].

Autoclaving

- ✓ The autoclave operates on the principle of the standard pressure cooker.
- ✓ The process involves steam at high temperatures.
- ✓ The steam generated at a high temperature penetrates waste material and kills all the micro organism .

In the Gravity type, air is evacuated with the help of gravity alone. The systemoperates with temperature of 121^{o} C and steam pressure of15 psi for 60-90 minutes. Vacuum pumpsare used to evacuate air from the Pre vacuum autoclave so that the time cycle can be reduced to 30-60 minutes. It operates at about 132^{o} C.Retort type autoclaves are designed to work at much higher steam temperature and pressure. Autoclave treatment has been recommended for microbiology and biotechnology waste, sharps and solid wastes. Autoclave treatment has been recommended for microbiology and biotechnology waste, waste sharps, soiled and solid wastes [11-16]. Common items from a hospital that should be autoclaved for sterilization include:

- Gloves, gauze, gowns, or other items worn by patients or doctors.
- Used bandages, Band-Aids, and gauze.
- Used or contaminated sharps (needles, syringes, scalpels, medical knives, etc.)

Microwave Irradiation

The microwave is based on the principle of generation of high frequency waves.These waves cause the particles within the waste material to vibrate, generating heat.This heat generated from within kills all pathogens.Irradiation attempts to sterilize waste by exposing it to gamma rays that are fatal to bacteria. A radioactive isotope of cobalt is employed. This is basically the same radiation source used for radiation treatment for cancer. In irradiation for sterilization of equipment or treatment of waste, the radiation is intended to kill pathogens, or probably any living cells. Ultra violet rays is lower frequency and generally less lethal than gamma radiation.

Chemical Methods

Chemical disinfection, primarily through the use of chlorine compounds, kills microorganisms in medical waste and can sometimes oxidize hazardous chemical constituents. Chlorine has been used for many disinfecting processes for years. Ethylene oxide treatment is used for disinfection and in treatment of medical waste. Ethylene oxide treatment is used more often to sterilize equipment that will be reused. This gas, mixed with air at a ratio of at least 3% EtOgas, forms an explosive mixture. Most of the time, it is mixed with Nitrogen or CO2.1 % of hypochlorite solution can be used for chemical disinfection.

Plasma Pyrolysis

Plasma pyrolysis is a technology for safe disposal of medical waste. It is an eco-friendly technology, which converts organic waste into commercially useful byproducts. The heat generated by the plasma enables disposal of all types of waste including municipal solid waste, biomedical waste and hazardous waste in a safest and most reliable manner. Medical wastes arepyrolysed into CO, H2, and hydrocarbons when it comes in contact with the plasma-arc. These gases are burned and produce a high temperature (around 1200^{o}C) [13-17]

Benefits of Biomedical Waste Management

- ✓ Cleaner and healthier surroundings.
- ✓ Reduction in the incidence of hospital acquired and general infections.
- ✓ Reduction in the cost of infection control in the hospital.

- ✓ Reduction in the possibility of disease and death due to reuse and repackaging of infectious disposables.
- ✓ Low incidence of community and occupational health hazards[18-20]
- ✓ Reduction in the cost of waste management and generation of revenue through appropriate treatment and disposal of waste.
- ✓ Improved image of the healthcare establishment and increase the quality of life[23].

Legislative Aspect in Relation to Biomedical Waste

Various central legislation related to biomedical waste management in India are as follows

- ✓ The water (prevention and control of pollution) Act, 1974
- ✓ The Air (prevention and control of pollution) Act, 1981
- ✓ The Environment(Protection) Act,1986
- ✓ The hazardous waste(management and handling) rules,1998
- ✓ The Biomedical waste(management and handling) rules,1998
- ✓ Municipal Solid waste (management and handling) rules, 2000
- ✓ The Biomedical waste(management and handling) rules Amendment ,2000 and 2003
- ✓ The Bio-medical Waste (Management and Handling) Rules, 2011 [Draft].

Recommendations

- ✓ Bio-medical waste should not be mixed with other waste of Municipal Corporation.
- ✓ Private hospitals should be allowed to use incinerator. For this purpose a specific fee can be charged from private hospitals.
- ✓ As provided by bio-medical waste rules, the whole of the waste should be segregated into colors due to their hazardous nature.
- ✓ Bio-medical waste management board can be established in every districts.
- ✓ Housekeeping staff should wear protective devices such as gloves, face masks, gowned, while handling the waste.
- ✓ There is biomedical waste label on waste carry bags.
- ✓

Conclusion

The segregation of waste at its supply is the key step to protect the environment. The challenge is to manage growing quantities of medical specialty waste that transcend past practices. If we would like to safeguard the environment and health of community we should sensitize ourselves to the present necessary issue. As a dentist we tend to do have some responsibility toward our surroundings and descendents. The method we dispose waste affects the standard of the atmosphere that we should expire to living standard of the future generations..The authoritative bodies in Asian nations and alternative developing nations ought to strictly implement and monitor biomedical waste management consistent with their needs during a systematic and oversimplified manner. The governmental bodies ought to take responsibility of creating these services obtainable to the active dentists furthermore at dental hospitals.

Abstract

Bleeding disorders are a group of disorders that share the inability to form a proper blood clot. They are characterized by extended bleeding after injury, surgery, trauma .Initial recognition of a bleeding disorders which may indicate presence of systemic pathological process may occur in dental practice. Oral care providers must be aware of the impact of bleeding disorders on the management of dental patients.With appropriate management strategies,nearly all bleeding disorder patients can benefit from the full range of dental procedures available to establish and maintain good oral health. Patient with bleeding disorders places a major challenge for dentists. Hence, adequate understanding of the medical conditions is essential to reduce the risk of dangerous complications and by providing required replacement therapy for the common bleeding disorders before the dental procedure and by theselecting the appropriate conservative treatment approaches, use of local hemostatic measure to facilitate haemostatis. From this review we can understand the types and management of bleeding disorders and its effects on the delivery of oral health care.

Key Word:*Bleedingdisorders, von willebranddisease,mennorahgia,thrombocytopenias,streptokinase.*

Introduction

Bleeding disorders are due to altered ability of blood vessels, platelets, and coagulation factors to maintain haemostasis. Most of the bleeding disorders are iatrogenic.These may be inherited due to genetic transmission or acquired secondary to diseases affecting vascular wall integrity, platelets, and coagulation factors or due to drugs, radiation or chemotherapy[1]. Three factors of haemostatis are vascular, platelet and coagulation phase is followed by fibrinolytic phase which forms fibrin as clot.

Vascular phase results in vasoconstriction of arteries and veins at the site of injury , it also builds up extra vascular pressure by blood lost from cut vessels and it lasts for seconds[2,3].

Platelet phase – it also known as primary haemostatis in which platelets interact with elements of the damaged vessel wall, leading to the initial formation of a “platelet plug”[2,3]

Coagulation phase - it takes place more slowly than other phases where blood lost into surrounding area and coagulates through both extrinsic and common pathways. Fibrin secure the primary platelet plug, exceptionally in larger blood vessels where the platelet plug is inadequate only to block hemorrhage[2,3].

Fibrinolytic phase – activates simultaneously with the coagulation and functions to maintain fluidity of blood during coagulation, serves as clot lysis and anti thrombic agents are released[2,3].

Coagulation casade –development of blood clot is changeover from a soluble protein fibrinogen into insoluble fibrin under the response of a thrombin. The conversion of prothrombin to thrombin involves a series of plasma serine proteases that normally exist ininactive and pro-enzyme forms[2,3].

Dentists may encounter patients with various types of bleeding disorders in their daily practice[4].Clinical bleeding can be presented in two forms:the first can occur during surgery and the second can manifest several days after the procedure.In both situations,the clinician need to take immediate action to control the haemorrhage and stabilize the patient[5].Dental procedures are associated with post operative bleeding .Procedures like extractions,oral surgeries

and periodontal surgery are the most common invasive procedures[6].In order to control haemostasis following an injury to blood vessel,a series of events is iniated are as follows:

- Local vasoconstriction
- Adhesion and aggregation of platelets
- Activation of the clotting casade to create a fibrin clot
- Activation of coagulation inhibitors to restrict coagulation to the site of the injury;
- Fibrinolysis occurs later to restore vessel potency[4].

Proper medical and dental reports of the patient is necessary before treatment ,especially if an invasive dental procedure is planned.Many bleeding disorders, such as hemophilia and Von Willebrand's disease run in a families; therefore a family history of bleeding disorders should be carefully elicited[7].This article is review on to understand causes of bleeding disorders prevailed during dental procedures.

Type of Bleeding Disorders

Congential Coagulation Defects

Haemophilia A is due to deficiency of clotting factor VIII. It is an inherited X-linked recessive trait found in 1:5,000 in the male population. Symptoms may include delayed bleeding,epitaxis,spontaneous gingival bleeding and hemarthrosis[9].Severe bleeding is seen when F VIII level is less than1% of normal. Severe hemorrhage leads to joint synovitis and hemophilic arthropathies, intramuscular bleeds, pseudotumors (encapsulated hemorrhagic cyst).Moderate bleeding is found when F VIII levels are 1% to5% of normal[10].Treatment for hemophilia is by administration of a intravenous replacement of Factor VIII or IX using purified plasma derived concentrates or rather by recombinant factor concentrates. Desmopressin (DDAVP) is used to achieve a transient increase in factor VIII level through the release of endogenous factor VIII in patients with hemophilia A and Von Willebrand's disease[11]. Haemophilia B is due to deficiency of F IX(Christmas factor).It is managed by replacement therapy with highly purified,virally inactivated factor IX concentrates. Factor IX replacementtreatment prothrombin complex concentrates is used [9].Von Willebrand's disease

is a unique disorder that was described originally by Erik Von Willebrand in 1926.It is an autosomal dominant trait with varying penetrance,defect is found in the F VIII protein complex. It is classified as type I to type IV and may vary in severity. For mild condition,use of DDAVP may be sufficient,bt severe disease warrants factor VIII replacement [11].

Rare Coagulation Factor Deficiencies

Rare coagulation factors deficienciesare Afibrinogenaemia, Factor II, Factor V, Factor XI and Factor XIII. These disorders are inherited as autosomal recessive traits and unambiguous clinically in homozygotes or compound heterozygotes. Treatment for rare coagulation factor deficiencies are fresh frozen plasma is used as the source for others(eg Factor V)[6].Fresh whole blood platelet concentrates, factor VIII concentrates[11].

Acquired Coagulation Abnormalities

Patients on eternal anti coagulant therapy with either warfarin or heparin are at increased liablity of bleeding with trauma or surgical procedures. In liver diseases,the synthesis of clotting factors may be reduced due to parenchymal damage or obstruction[6]. Management benefits for hemostatic shortage in liver diseasesincludes vitamin K and fresh frozen plasma in fusion for prolonged prothrombin time and partial thrombo plastin time;cryoprecipitate for replacement of factor VIII deficiency; and replacement therapy for disemminated intravascular coagulation[11]. Drug doses frequently needed to be modified in these patients due to impaired liver function. Warfarin, low molecular weight heparin and dicumarol are the commonly used anticoagulant drug[6].

Platelet Disorders

The large number of platelet disorder can be inherited and acquired and it is broadly categorized as defects of number(thrombocytopenia)or of function. Its classification is somewhatbased on the platelet disorders which are characterized by both decreased number and function[6]. Thrombocytopenias are primarily managed acutely with transfusions of platelets to maintain the minimum level of 10,000 to 20,000/mm^3 necessary to prevent spontaneous hemorrhage.

Congential Platelet Disorder

Congential abnormalities of platelet function or production are rare.Glannzmann's thrombocytopenia is a qualitative disorder characterized by a deficiency in the platelet membrane glycoproteins IIa and IIIb. Clinical signs include are brusing,epistaxis,gingival hemorrhage,and menorrhagia.Treatment of oral surgical bleeding involves platelet transfusion and use of antifibrinolytics and local heamoistatic agents[13,14].

Acquired Platelet Disorder

Idopatic or immune thrombocytopenia purpura(itp) and thrombotic thrombocytopenia purpura (ttp) clinical science are petechiae and purpura over the chest, neck and limbs . mucosal bleeding occur in oral cavity and git tracts. Thrombocytopenia is a component of other hematologic disease such as myelodysplastic disorder,aplastic anemia,and leukemia[13]. Alcohol can induce thrombocytopenia. Drug induced platelet is also part of thrombocytopenia,a large number of drugs attenuate platelet activity. The most common is aspirin,acetylates COX which blocks TxA_2 release from activated platelets.Other nonsteroidal anti-inflammatory drugs (NSAID'S)such as ibuprofen,naproxen,ketorolac and indomethacin inhibit COX.[6].

Vascular Disorders

Vascular defects are rare and usually associated with mild bleeding confined to skin or mucosa. It relates diseases such as epithelium and connective tissue of blood vessels. Scurvy (vitaminC deficiency) affects the formation of connective tissue and also perivascular connective tissue network and weakening of capillaries will lead to hemorrhage[15]. It can be treated with laser ablation and embolization.

Fibrinolytic Disorders

Disorders of fibrinolytic system can lead to hemorrhage when clot breakdown is enhanced ,or excessive clotting and thrombosis when clot breakdown mechanisms are retarded. They are two types of fibrinolysis are primary fibrinolysis and reduced fibrinolysis which is caused due to plasminogen activators,prostate carcinoma is caused when there is rise in plasmin levels and fibrinolysis. Medications are streptokinase,urokinase,TPA is used to accelerate clot lysis in patient with acute thromboembolism[17].

Laboratory Tests

Quantitative

Normal platelet count – 1,50,000 – 4,40,000/mm^3

Thrombocytopenia - < 150,000/mm^3

Bleeding time = 3-5 min

Clotting time = 4- 10 min

Partial thromboplastin time = 25-45 seconds

Thrombin time = 9-13 seconds

Qualitative

Ivy bleeding time = 1-6 min

Closure time from PFA 100 = 60-120 seconds [12].

Dental Management

Managing a patient with bleeding disorders is most important during dental treatment as it requires the infusions of clotting factor and medications to control bleeding. Based on the severity of conditon, invasive procedures to be planned in order minimise the hemostatis. Patient undergoing coagulation factors replacement or other anti platelet drugs must be noticed and stopped for certain periods and then proceed with treatment.

Pain Management

Dental pain can be contolled with analgesics and especially acetaminophen, codeine and cox-2 inhibitors must be advised carefully after a consulatnt of physician. During invasive procedures local anaesthic agent does not cause severe blood loss as it is combined with vasoconstrictors[11].Nerve block techniques is contraindicated in coagulopathies patient so prophylaxis is provided. Patient can be treated with general anaesthesia in case of factor

replacement defects. Infiltrations, intra ligamentary, intra osseous or intra pulpal injections are still safer[18].

Surgical Procedures

Extraction of tooth or other minor surgical procedures causes severe bleeding. Local hemostatic agents such as pressure packs, sutures, oxygel, surgicel, bone wax and other topical agents which are required during surgical treatments[23]. Patients undergoing warfarin therapy must be measured by INR [international normalised ratio] , if its greater than 3 treatment can be proceeded. Heparin taking patients can be treated in between dialysis as its short span is for 5 hours. Upatake of anti platelet drug should be stopped in order to lessen the increased risk of bleeding. Careful pre-operative planning and use of antifibrinolytic agents will reduce post operative complications. Desmopressin and tranexamic acid are primary alternatives[11].

Periodontal Procedures

Healthy periodontal tissue is essential to prevent bleeding and tooth loss. Periodontal problems is more troublesome in patients who has bleeding disorders experiences inflamed and hyperemic gingival tissues will be a source for the increased prospect of bleeding[10]. People will denied normal oral hygiene prophylaxis such as brushing of teeth, flossing etc. Patient undergoing factor replacement will require nerve blocks and periodontal packing , mouthgards will protect the surgical site from excessive bleeding. To achieve hemostatis post operative antifibrinolytic mouth washes can be used. On combination of 30% tricholor acetic acid with tranexamic acid was used to delay the bleeding in moderate hemophilia.Extremely inflamed and bloated gingival tissues are treated priorly with chlorhexidine oral mouthwashes or by gross debridement with a cavitron or hand instruments to allow gingival shrinkage prior to deep scaling[24].

Restorative Procedures

Usage of rubber dam, saliva ejectors and high speed suction can cause bleeding in ginvival tissue or oral mucosae so it must be handled carefully. Endodontic therapy might require factor replacement therapy. Restorative procedure can be undergone routinely by providing care,taken to protect the mucosa. Chances of severe bleeding is caused due to use of matrix bands or wooden wedges its controlled by application of topical agents[11].

Prosthodontic Therapy

Patient with bleeding disorders can usedentures as long as they are comfortable. Partial dentures isadvised so that the periodontal health of remaining natural teeth is maintained. Replacement of teeth does not involve much bleeding, oral tissues should be handled carefully on prosthesis fabrication and trial stages. Trauma should be minimal to soft tissues on post insertion process[17].

Orthodontic Treatment

Orthodontic therapy can take place without much bleeding complications. Care should be taken on using appliances which do not impinge soft tissue and provide atraumatic oral hygiene[11].

Oral Infections

Oral infections usually caused by streptococcus viridans, anaerobic gram positive cocci and anaerobic gram negative rods. Antibiotic regimes will control all these groups. Pencillin is first line drug regime to control oral infections. Metranidazole is combined with pencillin to treat aerobic and anaerobic bacteria present in oral cavity[11].

Conclusion

During anticoagulant medications, patient should be reviewed during their dental procedure periodically inorder to minimize the risk of thromboembolic complications. Dentist faces increasing numberof problem related to inherited,acquired and drug related associated with abnormal hemaostatic function. So we must maintain clear and open communication with patient and hematologist to ensure the contemporary information on the severity and control of the patients condition on and after dental procedures.

Abstract

Among the available blood group system, ABO system was first to be identified and Rh blood group system was the fourth one. Both are important for safe blood transfusion. A separate group called the Bombay blood group was categorised as the O group because it would not show any reaction to anti-A and anti-B antibodies similar to the O group. When a cross matching with O group is done, then it would show cross reactivity or incompatibility. Therefore, reverse grouping or serum grouping has to be performed to detect this group. Incompatibility in the context of blood groups is due to the binding of plasma antibody with red cell antigen, thereby causing a reaction. In laboratory tests this reaction is most commonly visualised by agglutination of the red cells. Therefore, proper blood matching should be done to avoid various complications.This article explains the importance of blood matching, the character of Bombay blood group and its complications as well.

Key Words: Bombay blood group, Cross matching, Serum grouping, Reverse grouping, Coagulation.

Introduction

Blood can save billions of lives. The need for blood and blood products in a country depends on the population, health care structure, prevalence of diseased conditions requiring regular transfusions, such as haemophilia and thalassaemia.The availability of surgical centresthat uses modern sophisticated techniques creates awareness amongst clinicians regarding judicious use of blood[1].The main objective of the blood bank is safe transfusion of blood from the donor to recipient without harming both. Landsteiner discovered ABO boood group system in 1901 and Rh system in 1940after which blood transfusion became much safer. Determining blood grouping and cross matching is an important prerequisite for blood transfusion. Nearly, 400 red cell antigens have been discovered till now. Among the available blood group system, the ABO system was identified first and Rh blood group system was the fourth one. Both are considered to be important for safe blood transfusion [2]. If proper blood grouping or testing practices are not followed, it can lead to people with Bombay blood group not being detected. This group would be categorised as the O group because it would not show any reaction to anti-A and anti-B antibodies similar to the O group. When a cross matching with O group is done, then it would show cross reactivity or incompatibility. Thus, reverse grouping or serum grouping has to be performed to identify this group.

There are four main blood groups identified. They are A, B, AB, and O [3]. If an individual has type “A” blood, this refers to them having an “A” antigen on the red blood cell. Subsequently, the patient with this type will have antibodies to type “B”. Those with type “O” blood type have no antigens present, but have antibodies to both “A” and “B” antigens. This is why type “O” blood is referred to as the universal donor. Conversely, those with AB blood types have no antibodies and therefore are considered as universal recipients of blood.

Bombay phenotype was first discovered in Bombay, India in 1952. In this blood group, no “A” or “B” antigens are detected on red blood cells or in other secretions and hence it is similar to “O” blood group. In Bombay phenotype, there is a void of A antigen, B Antigen as well as H antigen [4]. It is found that A and B blood groups are formed from the precursor carbohydrate H antigen. All blood cells, except for Bombay typeexpresses the H antigen. People having this blood type are mostly confined to Southeast Asia. About $1/10^{th}$of the population in that region have Bombay blood group. Mostly this Bombay phenotype is inherited by the offsprings from their parents. Caucasian incidence is 1/250, 000 [5].

When Bombay blood group is misdiagnosed, fatal hemolytic transfusion reactions occur. For this reason, and because of its rarity, inaccurate interpretation has led to these adverse effects[6].

In 1952 that Doctors Y.M. Bhende, H.M. Bhatia, C.K. Deshpande in Seth Gordhandas Sunderdas Medical College, Mumbai published an article in The Lancet (May 3, 1952) about two patients (X, a railway worker and Y, a stab wound victim) who required blood transfusion. No blood groups worked for them. The moment their blood samples were mixed with any other blood group types, the blood showed coagulation or clumping. Around 160 donors were tried for blood group matching and finally found one from Mr. Z, a resident of Bombay, suited the type of both patient X and Y. Thus, this donor blood group was then named as the 'Bombay Blood Type also called as hh group.

In 1955 Levine and associates reportedthe genetic suppression of blood group B in an American family in which 3 members were of the Bombay phenotype Oh- This convenient symbol was designated by Levine for persons with "Bombay" blood. In addition to the genetic suppression of blood group B, there was also evidence of suppression of the secretor gene »Se and the H antigen. In order to explain the phenomenon of the "Bombay" blood, 2 hypothetical genes were invoked, X and x. The former is very common and the latter very rare, but gene x in the homozygous state (xx) is responsible for the suppression of blood group substance B, the secretor gene Se and H antigen[6]. The characteristic features of Bombay blood group are absence of H, A and B antigens, no agglutination with anti-A, anti-B, or anti-H lectin, presence of anti-A, anti-B, anti-AB and potent wide thermal range anti-H in the serum, A, B, H non-secretor (no A, B, or H substances present in saliva) absence of H enzyme in serum and H antigen on red cell, presence of A or B enzymes in serum and red cell. Thus, the phenotype of Bombay blood group is considered to be recessive and the red cells of the Bombay group are compatible only withthe serum from another Bombay individual. This article aims at emphasizing the importance to detect the Bombay blood group and its need during emergencies.

Incompatibility

Incompatibility of blood groups is due to the binding of plasma antibody with red blood cell antigen and thereby resulting in antigen-antibody reaction. In laboratory tests, this clumping reaction is most commonly seen by agglutination of the red blood cells. In the body, an antigen-antibody reaction occurs as a result of errors in blood transfusion or pregnancy. These errors ultimately result inaccelerated destruction of red blood cells. It is therefore important to detect incompatibility between the plasma of a patient and the red blood cells of a potential blood donor before transfusion, to avoid a transfusion reaction. Incompatibility occurs in pregnancy when the mother is Rh negative and the foetusbeing Rh positive.

Antigen- antibody reaction occurs as the red blood cells crosses the placenta. This reaction occurs when the foetus has inherited a bloodgroupantigenfromthefatherwhichis ‘foreign’ to the mother. ABO system has the most important blood groups for blood transfusion. In pregnancy the D antigen of the Rh system from the foetus causes the reaction, ultimately resulting in erythroblastosis fetalis.

Antibodies are naturally produced in individuals who have never been transfused with red blood cells carrying the particular antigen or been pregnant with a foetus carrying the particular antigen. On studying about the presence of such antibodies, there can be some cells which may be capable of making specific antibody in the absence of antigenic stimulus or those antibodies, such as production of anti-A and anti-B as an immune response to substances in the environment which are antigenically similar to human blood group substances. For instance, the glycoproteins present on the surface of bacteria present in the gut are antigenically similar to the A and B antigens. Immune antibodies are formed and produced in response to an antigenic stimulus by a foreign antigen which may be due to blood transfusion or pregnancy. Any blood group can cause immune antibody production but out of all the blood groups the Rh system are the most common due to the presence of anti-D. Antibodies that are capable of causing an antigen-antibody reaction to blood transfusion or those which are harmful to a foetus are said to be clinically significant.

Blood group antigens are inherited characters by offsprings from their parents. These are detected by specific antibodies and may be protein or carbohydrate in nature. Though some are present on other cells and tissues of the body, the blood groups that will be referred to be those intrinsic to the surface of red cells. The genetic mechanism involved in the production of protein and carbohydrate antigens is completely different. Protein antigens (i.e. Rh) are direct products of their appropriate gene. However, the genes controlling the attachment of an immunodominant sugar to a cell membrane component encode transferase enzymes. Thus, carbohydrate antigens (i.e. ABO) are indirect products of the defining gene.

Laboratory Detection of Antigen-Antibody Reaction

Blood group antibodies are usually identified by a number of methods, known as serological techniques. Most of the methods utilise plasma or serum from the patient. Out of all the most commonly used is indicator of antigen–antibody interaction in blood grouping which results in agglutination, although haemolysis also indicates that antigen–antibody interaction has taken place.The agglutination reaction occurs when the repulsive forces that normally keep red blood cells apart gets overcome and also the multivalent IgM and bivalent IgG molecules

crosslink the red blood cells. The structure of the IgM pentamer which has 10 binding sites allows crosslinking more readily than the IgG monomer. IgM blood group antibodies are hence capable of acting as ‘direct’ agglutinins. Thus, if serum containing antibody is mixed with red blood cells possessing the specific antigen the cells will clump together ‘directly’, without an addition of anything else. This occurs because the pentameric structure of IgM ensures that the antibody molecules are close enough to link with antigens on two red blood cells and bind them together.Except IgG anti-A and anti-B, most IgG antibodies do not act as direct agglutinins. This is because there are a number of A/B antigen sites on red blood cells, which is about 100 times greater than D antigen sites. Indirect antiglobulin technique (IAGT) and potentiators like proteolytic enzymes can be used for agglutination ofIgG-sensitized cells.The action of proteolytic enzymes like papin on red blood cells may trigger agglutination in two different ways. One is it reduces the surface charge and allows red blood cells to come closer together and another by removing the structures which sterically interfere with the access of antibody molecules. However, we should realise that some blood group antigens are destroyed by papain and thus it cannot be used for the detection of all blood group antibodies.The antiglobulin test (AGT) was actually developed in 1945 and it still remains the most important and gold standard test for detecting clinically significant blood group antibodies. This test was named after its inventor and the test is called as Coombs test. The AGT test can be used as an indirect test (IAGT) to detect the presence of antibodies in the patient plasma or as a direct test (DAGT) to detect antibodies bound to red blood cells in the body. This test was very much useful in detection of red blood cells of babies with haemolytic disease of the newborn or patients with certain types of autoimmune haemolytic anaemia. In the AGT, agglutination is visualized by the addition of antihuman globulin (AHG) to the red blood cells which have sensitised antibody on their surface. It is usually washed in saline to remove residual unbound plasma proteins. In AGT unbound plasma proteins will bind with AHG and inactivate the reagent and hence washing with saline is an important procedure. AHGreagentsusually contain anticomplement (C3) as well as anti-IgG and also contain antibodies to human immunoglobulins. Methodology for performing the AGT has evolved since the usage of opaque glass tile. The tile is now replaced by the test tube, which today has largely been used bythe test name as ‘geltest’or‘column agglutination’ technology. In this the plasma proteins do not come into direct contact with the AHG, thereby neglecting the need for the washing procedure.

Screening of H-Deficient Phenotype

The presence of anti-H antibodies in sera was the first criterium used to define the Bombayphenotype.TheabsenceofH antigenonredcelsfromindividualswithcirculating anti-H was confirmed by hem-agglutination using the lectins Ulex europaeus and Lotus tetragonolobus and human anti-H sera from known Bombay subjects. With this protocol, the classical Bombay non-secretors were well detected. However, those with H-deficient erythrocytesandnormalABH secretionintheirsalivawerenotdetectedbecausethey generally have very low or undetectable titers of anti-H. This protocol is justified, in routine large-scale typing, for clinical reasons because the classical Bombay non-secretors with high titers of anti-H antibodies are susceptible to transfusion accidents if transfused with non-Bombay blood, while H-deficient secretors have a much lower risk of transfusion accidents. Although H-deficient secretors are interesting from a scientific point of view, they were unfortunately missed in our study[8, 9].

Genetics of Bombay Phenotype

Ceppellini suggested that this blood group results from the presence of homozygous recessive gene which inhibits the formation of A,B and H antigen. Subsequently, Watkin and Morgan postulated that the H antigen might be the product of the gene independent of A-B-O system and that the Bombay phenotype is the rare homozygous hh. Levine demonstrated the effective suppression of expression B and secretor gene by the Bombay phenotype extracted from a family of Italian-American. This same family also showed that the H-h locus was not linked to the A-B-O locus. A total of thirteen families with individuals of the Bombay phenotype have been reported from India. These have occurred in multiple castes and in both Hindus and muslims. Inaddition, Italian-American, Irish, French-American, English-American and German family studies have been reported. Although the frequency of the h gene is quite low, it appears to be present in widely separated population groups.

The results of family studies, serologic and biochemical investigations have shown that the A,B,H and Lewis antigens are the products of sequential action of transferases that modify a common precursor substance. The products of A and B genes are glycosyl transferases that add either N-acetylene-galactosamine or galactose to the terminal galactose residue of the H-substance. A fucosyl transferase is the product of H gene and adds a fucose residue[10].

In Bombay phenotype A, B, and H antigens are absent on its red blood cells and the serum of these individuals have anti-A and anti-B.But the serum that agglutinates red blood cells of

‘O’ group individuals, occurs due to presence of strongly reactive anti-H antibodies. It was identified that the h allele is a result of mutation of the H gene (FUTI) that would express the H antigen on the red blood cell of ABO blood groups. Bombay phenotype is homozygous (hh) for the 725G mutation in the FUT1 coding region; the consequence of this mutation is the production of an inactivated enzyme, the enzyme needed in the production of the H antigen. The H substance is bio-chemically produced by the binding of Fucose to the surface glycoproteins. This process iscatalysed by fucosyltransferase. When N-acetyl-galactosamine binds to the H substance, Blood group A gets formed. Blood group B is formed when galactose binds to the H substance. If neither occurs, that is, if the substance does not bind to H, then resultant will be ‘O’ blood group. Individuals that fail to express H transferase (FUT1) lack the H antigen, which is the foundation of Bombay phenotype. Few individuals cannot synthesize A or B antigenic structures as they lack the expression. It is also found that ABH antigens are absent from both their erythrocytes and secretions.

The practice of tribal and territorial endogamy is small population leads to smaller gene pools. Consequently, increased expression of homozygous genetic characters like Bombay phenotype occurs. Many studies show that in India consanguineous marriage is commonly practiced.During cell grouping or forward grouping, Bombay blood group would be categorized as O group because it would not show any reaction to anti-A and anti-B antibodies just like a normal O group would do. Cross reactivity or incompatibility was seen when cross matching with different blood bags of O group was done. Hence a thorough evaluation should be done for identification. Therefore, for detection of Bombay blood group, reverse grouping or serum grouping has to be performed. Thus, this method which is serum grouping or reverse grouping has to be performed in every transfusion medicine department, blood bank or blood donor centres so as to reduce the risk of fatal hemolytic transfusion reactions.The concern with Bombay blood group is that the individuals having this group can only receive either autologous blood donation or blood from an individual of Bombay phenotype [11]. In case of emergency situation, it is important to detect Bombay blood group as it may cause lethal effects on the recipient. Hence individuals identified with Bombay blood group should make all their family members and relatives tested for the blood group. They should also register themselves with leading blood banks so that they can be helpful in case of emergencies [12]. In other suggestions, cryopreservation facilities for rare donor units have been recommended.In the event that the blood banks can borrow or trade uncommon blood units in times of require, a part of issues related to uncommon blood bunches just like the Bombay blood group can be unraveled. Typically, as it were conceivable in case each

blood bank features a huge number of committed customary deliberate givers [13]. In the absence of blood donor registry, transfusion management of patients needing immediate surgery can be challenging. Acute normovolemic hemodilution (ANH) is a blood conservation technique that entails the removal of blood from a patient shortly after induction of anesthesia, with maintenance of normovolemia using crystalloid and/or colloid replacement. The blood is infused into the patient during or shortly after the surgical procedure [14]. ANH is available, cost effective for suitable patients and reduces blood viscosity [15]. Newer research with stem cells has provided an opportunity to produce a universal bloodgroup donor, in vitro, thus enabling cellular replacement therapies, once the safety issue is resolved [16].

Prevalence of Bombay Blood Phenotype

Bombay blood group was first reported in 1952. Bombay phenotype is seldom, since it is found to occur in about 1 in 10,000 individuals in India and 1 in 100,000 individuals in Europe.Regarding the distribution and spread of the Bombay phenotype in different states of India, it is found that this type of blood group is more common in the states of Western and Southern parts of India as compared to other states. Most cases belonged to Maharashtra from the 179 cases recorded at that time. A slightly higher frequency of the Bombay phenotype was also found in the neighboring state of Karnataka (15 cases), Andhra Pradesh (8 cases), Goa (6 cases), Gujarat (5 cases), Uttar Pradesh (5 cases), and so on in the decreasing order[17]. A person with this rare group should always be cautious and alert. People with this blood group can donate blood to any ABO group, but as this blood group is rare one shouldn’t be advised to donate to any other groups. And they should maintain healthy body to avoid Health problems.

Fate of Bombay Blood Group

In Bombay Blood group people, without fucose, neutrophils lack sialyl Lex and thus cannot roll and ingest bacteria. Thus, these patients can have high white blood cell count and severe recurrent infections. This condition is called leukocyte adhesion deficiency II or congenital disorder of glycosylation II[18]. Since this blood group is found to be rare, it would be difficult even for the blood banks to acquire these groups in their bank and use them in case of emergencies. Those anticipating the need for blood transfusion (e.g. in scheduled surgery) may bank blood for their own use (i.e. an autologous blood donation), but this option is not available in case of accidental injury.

If patients with anti-H in their circulation receive transfusions of blood that contains the H antigen (e.g., blood group O), they are at risk of suffering an acute hemolytic transfusion reaction.The maternal production of anti-H during pregnancy in an O_h phenotype mother could cause hemolytic disease in a foetus who did not inherit the mother's Bombay phenotype[19,20].

Conclusion
